the earlier part of the 17th, legal medicine made marked progress. Ambrose Paré, whom Foderé mentions as the first writer upon the subject in France, published during that time a treatise upon tardy births. Fortunatus Fidelis compiled and published at Palermo in 1602 all that was then known of medical science. At Rome, about 20 years later, Paolo Bacchia, or, as he is usually called, Paulus Bacchias, commenced the publication of his celebrated *Quæstiones Medico-Legales*. This famous work appeared in successive volumes between the years 1621 and 1650, and for its completeness and great learning deserves the merit of first worthily exhibiting legal medicine as a science. In France in 1609, under a patent of Henry IV., two surgeons were appointed in every considerable town to make examinations and reports in all cases of wounded or murdered persons. During this period the application of the so called hydrostatic test of Galen to cases of supposed infanticide, which had been suggested by Harvey, was discussed in several disquisitions by Bartholin (1668), Swammerdam (1677), Jan Schreyer (1682), and toward the close of the century by the celebrated Bohn, in his treatise *De Renunciatione Vulnerum*. In a later work Bohn treated of the office of the physician as expert in judicial tribunals. France produced during this time no very celebrated works on forensic medicine, but the *Doctrine des rapports en chirurgie* of Blégné (1684), and the more useful book of Devaux on the same subject, are honorably mentioned in this branch of the science. In 1722 Valentini contributed to the literature of the science the *Pandectæ Medico-Legales*. Between 1725 and 1747 were issued at Halle the successive volumes of the *Systema Jurisprudentiæ Medicæ* of Albertini. Among the more excellent portions of the work, those upon conception and utero-gestation are said to have discussed these topics with great ability. This work was followed by the *Institutiones Medicinæ Legalis vel Forensis* of Tischmeyer. The merit of this work may be inferred from the fact that it was used for a long time as a handbook in the German universities, and formed the text of Haller's celebrated lectures, which were published after his death in 1782 and 1784. The *Elementa* of Plenck (1781) and the *Systema* of Metzger (1795) are commended by writers of high authority. So too is the collection of Metzger's constitutions or opinions, many of which embody the results of his studies in mental disease as a branch of legal medicine. The *Collectio Opusculorum*, edited by Schlegel, and embracing upward of 40 dissertations by German authors on various topics, was one of the most valuable additions made during the 18th century to the learning of the science. During the latter part of the 18th century, infanticide was made the subject of elaborate research by Daniel and Ploucquet, among others, the latter of whom published an essay upon the evidences of respiration in new-born infants; and by Metzger, Portal, and Camper, of whom the last wrote upon the signs of life and birth

in new-born infants, and upon the causes of infanticide. During the same period the eminent French surgeon Antoine Louis, both by private dissertations and by his opinions pronounced before the tribunals, contributed to the illustration of some of the most difficult topics in legal medicine. Among the former are his memoirs upon tardy births, on the certain signs of death, on drowning, and on the mode of distinguishing between suicide and assassination in the case of a body found hanged. But his opinions, many of which are collected in the *Causes célèbres*, present perhaps the clearest evidences of his genius. A valuable memoir upon death from blows or wounds was read by Chaussier at Dijon in 1789, and the next year he delivered there a course of lectures upon legal medicine. Just before the close of the century in 1796 Foderé published *Les lois éclairées par les sciences physiques, ou traité de médecine légale et d'hygiène publique*. This treatise displays the entire system of the science. Dr. Parr published in England in 1788 the "Elements of Medical Jurisprudence." This book was a mere compilation from continental authorities, but was, at the time, the only English work upon the subject. In the first year of the present century, the first lectures in Great Britain upon medical jurisprudence were delivered at Edinburgh by Dr. Andrew Duncan, and in 1806 the first professorship was established in the same city, and conferred upon Dr. Andrew Duncan the younger. The most important accessions to the science of legal medicine during the last 50 years are those derived from studies of mental disease, and the application of the knowledge thus obtained to determining questions of legal responsibility; and from investigations into the nature and effect of poisons, and of the mode of detecting their presence in the human body. The first systematic work of this century is the posthumous one of Dr. Mahon (1807). He was professor of legal medicine at Paris, and occupied one of the chairs which, by the exertions of Chaussier, Fourcroy, and others, had been established by the revolutionary government. In 1808 Marc published a translation of the German work of Rose on medico-legal dissection, to which he added valuable original notes and essays. Foderé in 1818 issued a second and much enlarged edition of his treatise. Of a far higher character than any work which had preceded it was the *Toxicologie générale* of Orfila, which appeared in 1814, and was followed 5 years later by his *Leçons de médecine légale*. Orfila has rendered the most eminent services to the science, and particularly in the department of toxicology. The elaborate treatise of Devergie made still further advances alike in the theory and practice of legal medicine. Briand, Capuron, Biessy, Esquirol, and Marc are authors of learned treatises or of dissertations on single subjects. But any sketch of the French literature upon this subject would be incomplete without mention of the *Annales d'hygiène et de médecine*, a quarterly journal,

which from its first appearance in 1829 to the present time has been supported by the ablest medical men of France, and is an invaluable repository of information on the various branches of medical jurisprudence. The Germans still maintain their high rank in this science. Schmidmüller, Willberg, Gmelin, Remer, Bernt, Henke, and many others have made the most various and valuable additions to the learning of medical science and jurisprudence. The principal Italian authors of the present century are Tortosa, Martini, and Barzelotti. In 1815 Dr. Male produced the first respectable English work on forensic medicine. More comprehensive and better in many respects than any which had preceded it, was the treatise of Dr. John Gordon Smith (1821). Two years after appeared the more formal and elaborate work, the result of the combined labors of a lawyer and a physician, Messrs. Paris and Fonblanque. Dr. Christison's works on poisons are of the highest excellence. Haslam on insanity, Hutchinson on infanticide, Watson on homicide, Gavin on feigned diseases, Taylor, Guy, and Traill, are authors of high eminence in their various specialities. Lectures upon medical jurisprudence were first delivered in America in 1804 at Columbia college, by Dr. James S. Stringham. In 1815 Dr. T. Romeyn Beck was appointed to lecture on the science in the western medical college, and not long after Dr. Walter Channing received a similar appointment in Harvard college. American authors have furnished to the literature of medical jurisprudence some of the very best works upon the science. The well-known work of Dr. Beck, which has just reached its 11th edition, has been lately pronounced by Dr. Traill of Edinburgh to be the best book on the general subject in the English language. American editions of various English works, and the publication during the present year of the very excellent treatises of Wharton and Stillé, of a 4th edition of Dr. Ray's celebrated book on insanity, and of Elwell on malpractice, maintain the high reputation of our country in its culture of medical science and jurisprudence.—The very general survey of legal medicine which is here proposed will exclude all notice of medical police or public hygiene, and will be exclusively limited to a brief review of the more prominent branches of the science. Following the division of Briand, the subject may be conveniently arranged under three heads; the first embracing those branches which concern the reproduction of the species; the second considering injuries to health and life, the different forms of death by asphyxia, and the nature and effect of poisons; the third examining mental affections.—In the male, absolute and incurable impotence may arise from total absence, unnatural form, or paralysis of the organs of generation. Curable conditions may be the consequence of disease or sensual excesses, or of slight malformation which can be relieved by surgery. Accidental and temporary incapacity may be caused by nervous or malignant fevers,

particularly if they affect the brain and are accompanied by great debility, all affections of the head and spinal marrow, palsy, apoplexy, and the like diseases. This class of causes usually comes to be considered upon questions of contested paternity; for if it appear that any of these existed at the time of the child's conception, the presumption is strong against its legitimacy. In the female, malformation may render intercourse impossible. If it existed at the solemnization of the marriage and be incurable, it is sufficient ground for divorce. Female impotence may also be caused by diseases which may yield to medical treatment. In two instances familiar to the theory of the common law, though rare perhaps in its administration, medical testimony may be invoked by the courts upon the question of pregnancy: first, where a widow is thought to feign herself pregnant in order to supply a supposititious heir to an estate; and secondly, where a female condemned to death is supposed to be in that condition, for her execution will be delayed if she be quick with child. But in other respects, and particularly in relation to abortion and infanticide, the existence of pregnancy may be a significant fact. In respect to the crimes of abortion and infanticide, and also with reference to civil cases, when questions of heirship are involved, it is important to consider the signs of a child's death before or during delivery. From the sound health of the woman, and the usual signs of a healthy pregnancy, nothing can be conclusively presumed respecting the life of the foetus; and on the other hand, though violence and those other causes which tend to produce miscarriage may and usually do destroy the foetus, yet infants sometimes survive all these. The signs of death during pregnancy are numerous, and yet equivocal. Auscultation is one of the surest means of detecting foetal life. After the birth, the physician can judge from the appearance of the body, from the condition of the flesh, from its color, from the condition of the umbilical cord, and of the bones, whether the infant was dead or alive at delivery. The successive stages of foetal life, as they are marked by the size, weight, and development of the organs and functions of the child, should of course be familiar to the physician; they will throw much light upon the matter in question. In its latest researches science has found that the changes in the brain furnish an index of the general development. Yet all inferences derived from the structure and dimensions of the foetus will be modified and controlled by considering the age and vigor of the mother, her mode of life, and perhaps the climate in which she lives. All systems of law contain provisions respecting newly born infants. To succeed to property, according to the Roman law, the infant must be perfectly alive. The English law makes a like requirement. By the French civil code the child must be viable, or capable of life, in order to be capable of inheriting; and on the authority of the most

eminent surgeons and jurists of France, life, or being born alive, means complete and perfect respiration. The viability of a child, that is, its capacity of life, comes then to be considered in questions of property, and of the division of inheritances; for a child which is declared by medical science to have been viable may be presumed to have lived, and so to have inherited. "It is now very generally conceded," says Beck, "that no infant can be born viable until 150 days, or 5 months, after conception. The instances of exception to this rule are questionable; indeed, the survival of infants born at 6, 7, or even 8 months after conception, is by no means frequent." The criminal destruction of the foetus while still in the womb, generally described by its consequence as abortion, is more fitly named foeticide. Unlawful attempts to procure birth are variously punishable in the law as felonies or misdemeanors. In England, since the statute 1 Victoria, c. 85, an attempt to procure an abortion with the mother's consent, and before the foetus has quickened, is declared a felony. Whether in such a case an indictment lay in this country at common law has been variously determined; but statutes have now very generally disposed of the matter, and it is the tendency of later and better legislation, as it is also conformable to the teachings of medical science, to regard quickening of the child as no longer essential to the criminality of an unlawful abortion. The duty of the medical expert in cases of supposed foeticide (for in a medico-legal point of view that is the proper term) is to determine whether the substance expelled from the womb be really the product of conception; whether this was the germ of a human being; and also whether the causes of miscarriage were natural or artificial.—Infanticide is the murder of a child born alive. Here the medical examiner must address his inquiries first to the appearance of the body in order to determine whether it was born alive. If that be clear, he will seek to determine how long it lived, and the means by which it came to its death. These inquiries will naturally involve an examination of the female alleged to be the mother. Proof that life has existed in the child may be derived from the effects of respiration upon some of the organs of the body. In a child which has breathed completely and fully, the thorax will be found expanded and the diaphragm more or less depressed by the inflation of the lungs. These signs alone are not, however, of much value. Respiration will also have distended the lungs, and increased their volume, and will have changed their color from the brownish tint of the foetal lungs to a pale red or scarlet color. After respiration the lungs become soft and spongy, and they crepitate more or less upon pressure. The hydrostatic test is often applied. Galen had taught that by inspiration the lungs are rendered specifically lighter, and in modern times the test was first applied by Schreyer in 1682 to cases of suspected child

murder. In the course of experiments it has been found that the lungs may float from other causes than respiration, as for example from putrefaction, or the artificial introduction of air. But, observing certain precautions, it may be certainly known to what cause the buoyancy is due. If, says Beck, with such precautions it be found that the lungs float in the water, as well with the heart attached to it as separate from them; if when cut into pieces each fragment floats, then the proof is strong that the infant enjoyed perfect respiration. Something may also be concluded, though not with much certainty, from the character of the blood found in the body, but more from the changes in the blood-circulating organs which are known to be wrought by the establishment of respiration, as, for instance, in some of the vessels and ducts of the heart, and in the arteries and veins of the umbilical cord. The separation of this cord, in the living child, is preceded by several stages of desiccation; and if this characteristic be present, its condition will afford evidence of the infant's age. To the validity of these indicia, so far as they tend to show the fact of life, it has been objected that the child may have breathed during delivery, and yet have died before it was fully born. It is replied to this, that the fact of breathing during birth affords the best presumptive evidence that the infant was born alive, and that the marks of any accidental cause of death will generally be discovered on inspection. More than that, respiration in such cases is commonly imperfect, and the objection will therefore have but little weight where the body presents the appearances which are induced by complete respiration.—If the examination lead to the conclusion that the child was born alive, the means of death must next be determined, and whether they were innocent or criminal. The omission to tie the umbilical cord, permitting fatal hæmorrhage by its severed vessels, may be a cause of death. In such a case the body presents externally a singular paleness, and a peculiar waxy appearance. Internally is observed a loss of color in the muscles and viscera, and absence of the usual quantity of blood in the heart and blood vessels. Exposure to cold immediately after birth, want of proper nourishment, the infliction of blows and wounds, the thrusting sharp instruments into various parts of the body, are frequent modes of child murder. In cases of strangulation, suffocation, and poisoning, the indications of the cause of death are evident, and are suggested under the proper divisions of this article. It must be remembered also that accidental causes attendant upon birth, congenital disease, malformations or defects of internal structure, may deprive the child of life or render it incapable of living. The mother may have been overtaken by the pains of labor when alone and unassisted, and then there are many chances against the safe delivery of the infant. Fainting or convulsions, which sometimes attend labor, may render her incapable of ministering

to the first wants of her child; unskilful and imperfect ligature of the umbilical cord may produce death. An examination of the supposed mother has already been suggested.—In determining questions of legitimacy, the consideration of premature and tardy births necessarily arises. The ordinary period of gestation, derived from accurate data, is fixed at 10 lunar months, or 280 days. It is admitted on high authority that this time may be exceeded, but it has been suggested that the apparently exceptional cases may be explained by the fact of inaccurate computation. Still it is to be remembered that the human foetus is ordinarily expelled only when it has attained sufficient development, and that, as this may be delayed by disease or other causes, it is not strange that delivery may be for a longer or shorter time deferred. Whether a child born before the time expected is to be regarded as legitimate, has been already incidentally discussed. It has been seen that the best authorities deny that a perfectly natural child can be born in less than 7 months after conception. The absence or incapacity of the husband during this period, and all other causes which render intercourse impossible, tend strongly to prove illegitimacy of the child. Births occurring at 18 and even 14 months after an alleged coition have been sometimes claimed to be legitimate. This topic of protracted gestation has been abundantly discussed by medical writers. It must suffice here to say that, though the theory seems to be well opposed by many, it is yet favored by a majority of the authorities, among whom are included Bacchias, Haller, Petit, Foderé, Capuron, Orfila, and others of almost equal eminence. It may be added that, of the cases cited in support of this theory, the best authenticated are those in which the ordinary period of gestation was exceeded only by 3 or 4 months. But in a case of questioned legitimacy this eccentricity of nature is too marked to allow a too ready admission of its probability.—When a person is found dead under circumstances which render the cause of death doubtful, the medical expert may be called upon for an opinion whether death resulted from natural causes, or had been produced by violence; and, if by violence, whether that was self-inflicted or proceeded from the hands of an assassin. Under this division of our subject we propose to notice some of the more usual and characteristic phenomena observed in cases of death by blows and wounds; by asphyxia, considering here drowning, hanging, and suffocation; and finally, by poisons. The appearances in the body which are caused by effusions of blood, will attract the early attention of the examiner. He will determine whether these are in the nature of ecchymosis or of sanguinolence. When a blow or contusion is sufficiently violent to rupture blood vessels, the effused blood spreads into the cellular tissues and forms ecchymosis. The intensity and gradation of color in these spots give clear indications of their cause, and the freedom of the blood-

rhage shows that they were produced during life. Ecchymosis is named traumatic when, as is usually the case, it proceeds from external causes, and spontaneous when it is the effect of internal violence. From this must be distinguished the post-mortem appearances caused by agillation. This is the term applied to the determination of the blood, merely as an effect of gravitation, into the lower lying portions of the dead body, and into the capillary, and not into the cellular tissues. Ecchymosis may be imitated on the dead body within a short time after life is extinct; but very violent blows, inflicted then, will produce only the same effect as slight contusions during life. The body may plainly show, or dissection may disclose, that death was caused by wounds, that is to say, in the language of legal medicine, by a lesion of any part of the body. It may be remarked in passing, that, in law, a wound means a breaking of the skin, at least, by the application of extreme violence. A division of the cuticle alone is not sufficient. The true skin must be penetrated, though there be no effusion of blood. In surgery, a wound means a solution of continuity in the fleshy parts. The first inquiries of course will be whether the wounds discovered were self-inflicted, or resulted from accident, or were given by a homicide. The position and direction of the injuries will be noted. The presence of many wounds argues violence by another hand than that of the deceased. The suicide generally directs the hurt to a single vital point. A wound made by a cylindrical and pointed instrument has distinct angles. A cut is larger than the cutting edge, and in the living body is always accompanied by some effusion of blood. A wound by a perforating instrument is generally smaller than the instrument which inflicted it. The entrance made by a ball is distinguished by the regular roundness and depression of its edges; the exit wound is torn and ragged. The former is also larger than the latter. The spiral direction given by the rifle ball causes a more ragged wound than that produced by a ball from a smooth-bored arm. A single round wound can be produced by a shot charge only when it is fired at a distance of 10 or 12 inches, and then the injury is not the same as that of a ball, but is more extensive and more serious. The examination of spots supposed to be made by blood may lead to important discoveries. Blood washed from linen into water imparts to it a deep red color; boiling produces a muddy brown precipitate which is to be subjected to chemical tests. In fresh blood the microscope reveals the presence of red flattened disks, which are the blood disks, and among these, more rarely, the rounded colorless lymph globules. These latter may still be observed under the microscope in the water in which dried blood has been softened; the blood disks are less easily obtained. It is often a question for the medical expert, when disease has succeeded to the injury, whether death re-

sulted from the one cause or the other. If malignant or inflammatory symptoms follow upon slight wounds, the inference is ordinarily not difficult that the injury was not the cause of death. The habitual use of intoxicating liquors tends to induce a diseased condition of the system, and in a state of actual drunkenness the vessels of the body are in that condition in which an external injury is apt to produce rupture, and a less violent blow will cause it than would otherwise be required. Legal responsibility rests on the clear and direct consequence of the injury inflicted. This principle must always be borne in mind. For disease, though developed in organs far from the seat of the wound, may yet be its immediate result; as, for example, injuries of the head may promote a deposition of pus in the lungs, or give rise to abscesses of the liver; and on the other hand, death may result from improper medical treatment, or from the negligence or excesses of the injured party himself. (For the subject of malpractice, see *PHYSICIAN*.) Though external marks fail, the skilful anatomist may discover upon dissection internal signs of mortal injuries. Blows or wounds upon the surface of the body may possibly rupture the heart. Ruptures of aneurisms may be produced by the excitement of passion, and laceration of the spleen or liver by a fall or other sudden external violence. Death from starvation is characterized by distinctive phenomena. The body is extremely emaciated, and, even though death were recent, exhales an acrid and fetid odor; the eyes are red and open, the tongue and throat dry, and the stomach and intestines empty; the blood vessels are quite empty, and the intestines inflamed and ulcerated.—When life has been destroyed by the inhalation of noxious vapors, as for instance of carbonic acid or sulphuretted hydrogen gas, the head and face are found to be swollen, the eyes protruded, and the tongue fixed between the teeth. The face, if observed soon after death, may be pale, but generally soon becomes livid. The blood vessels of the head and lungs and the right vessels of the heart are filled with dark fluid blood. Pure carbonic acid gas is irrespirable, and inhalation of it causes death rather by asphyxia than by poisoning. When mixed with oxygen, 10 per cent. of this gas is very promptly fatal to life, and even a smaller proportion may produce the same result. Death from asphyxia is caused in various ways. When respiration is checked by mechanical compression of the organs which perform that function, or when it ceases either from want of air, as in cases of suffocation and strangulation, or from failure of vital air, and the inspiration of mephitic or deleterious gases, death is caused by asphyxia. Properly speaking, death ensues in those cases from non-aëration of the blood. It is preceded and accompanied by marked phenomena, more marked and evident in proportion to the rapidity with which death advances. In a violent struggle for breath, the eyes become distended, the veins

swollen, and the face is fully suffused. On dissection, the pulmonary vessels and the right auricle and ventricle of the heart are found charged with blood, the liver, spleen, and kidneys are gorged, and the lungs expanded. In cases of less violent death, where, for example, it is brought about by inhalation of noxious gases, these appearances are less strongly marked.—Hanging sometimes causes death by producing congestive apoplexy, the pressure of the cord preventing the return of blood from the brain, while it does not check the circulation by the intervertebrals; but more frequently the destruction of life is due to asphyxia. Luxation or fracture of the cervical vertebræ speedily causes death. The signs of strangulation are a livid depressed circle upon the neck, made by the cord; the face is distorted; the eyes are open and protruded; the face, shoulders, and chest swollen. The ecchymosis produced by the cord is an important sign, for, as has been already observed, ecchymosis is possible only when contusion of the tissues takes place in the living body; yet in inferring the mode of death it is to be remembered that as death in hanging may suddenly result from luxation, the cord may have had no time to act on living tissues. The condition of the genital organs also affords very important proof of death by hanging. The color of the countenance is also to be regarded. If the trachea or larynx was alone compressed, the face is pale; but when the veins of the neck were pressed, as by the cord, and the heart continues for some time its action, the blood is propelled into the head and causes suffusion of the face.—The question may arise whether, if the deceased came to his death by hanging, that were his own work, or the work of a homicide. An examination of cases of suicide has shown in a large proportion of them the absence of ecchymosis; and this because from the employment of less violence the contusion of the neck was less. Fracture of the vertebræ of the neck is often caused in execution by the fall of the body, or even by force which is sometimes applied by the hangman. But luxation is of course not conclusive evidence of homicide. An examination of the position of the body and of the objects which surround it, of its elevation above any possible support, and any marks which show resistance, must be made in all suspected cases. In strangulation, in its ordinary sense, death results not from fracture of the vertebræ, but from interruption of respiration. This is a rare mode of suicide, and when appearances indicate that it was the means of death they raise a violent presumption of assassination. Because death ensues from interruption of the breath, the mark of the cord must be quite distinct, and is rather horizontal than oblique. Bruises of peculiar form around the neck may show that strangulation was effected by the hands. It is impossible that these should have been made by the suicide, because the hands lose their power as insensibility progresses. In cases of hysteria, apoplexy, or epilepsy,

the sufferer may, however, in his agony have pressed the hands to the throat, and in this way have made the marks which give rise to a suspicion of murder.—Obvious and distinctive marks are, says Dr. Christison, rarely present in a case of death by suffocation. They are the less evident as death is the more rapidly induced; for if there be no time for the accumulation of blood in the venous system, there will be no enlargement of the pulmonary vessels, no turgescence of the veins, and no discoloration of the skin. In the cases which occurred in the Champ de Mars in Paris in 1837, of suffocation by pressure in the crowd, when death was probably caused by respiration being incomplete, and was long deferred, the bodies of the dead exhibited peculiar appearances. Their faces and necks were of a uniform violet tint, spotted with blackish ecchymosis, and in some instances blood and froth oozed from the mouth and nostrils.—As in hanging, so in drowning, life is destroyed by different modes, sometimes by suffocation, or rather by the asphyxia which that causes. This is the most usual form of death by drowning. Another form is that of syncopal asphyxia. In these cases, the coldness of the water, or perhaps intoxication, throws the system into a condition of nervous inaction, and the body presents only the appearance of simple asphyxia, paleness of the body, no froth in the trachea or bronchi, and but slight disturbance of the internal organs. Still another cause of death is apoplexy from cerebral congestion. A drowned body usually presents general paleness of the skin, yet the face will be discolored if death were preceded by long-continued struggling. It is to be remarked that upon exposure of the body to the air, discoloration very speedily ensues. The eyes may be found half open, attended by dilatation of the pupils. These signs, as also frothing at the mouth, may proceed from other violent means, but still are strong proof of drowning. Of the internal appearances of the body may be mentioned a fulness in greater or less degree of the blood vessels of the head and of the right side of the heart. The congested condition of the brain varies with the proximate cause of death. If that were apoplexy, it would certainly be present, but rarely or not at all in the case of syncopal asphyxia. The blood of the drowned is generally found fluid. The existence of froth in the bronchi is perhaps not a conclusive proof of the mode of death; but it is certainly the result of vital action, and so may be a valuable sign in conjunction with others to prove that life existed when the body was immersed. The presence of water in the stomach is merely accidental, and is not very nearly connected with the cause of death. As upon high authority it is asserted that water cannot pass into the stomach after death, its presence in it may be in certain instances significant. When death arises from obstruction of the breath by water, and not by apoplexy, some of the fluid enters into the lungs with the last efforts of inspiration.

Yet neither the fact that it is found there, nor its quantity, can be regarded as proving conclusively that death took place in consequence of immersion; for under favorable circumstances water may penetrate into the lungs even of a dead body.—Foderé defines poisons as those substances which are known by physicians to be capable of altering or destroying, in a majority of cases, some or all of the functions necessary to human life. The intent with which such a substance is administered enters of course into the legal conception of a poison. Poisons may be ranked under the two great divisions of irritant and narcotic. To irritant poisons belong the acids and their bases, the alkalies and their salts, the metallic compounds, and the vegetable, animal, and mechanical irritants. The characteristic of these poisons is the inflammation which their application excites. Their most notable effects upon the human body are heat, irritation, or singular dryness in the œsophagus, accompanied by a sensation of strangling; pain in the stomach and intestines or in the region of the kidneys, followed by strangury; evacuations both by vomiting and at stool, convulsions, faintings, cold sweats, and an irregular thready pulse. There is, usually, a retention of the intellectual faculties until the disease approaches a fatal termination. Narcotic poisons, on the other hand, which include many vegetable substances, prussic acid and its compounds, and the narcotic gases, nitrogen, carbonic acid and oxides, oxygen, hydrogen, and others, are distinguished by the disorders which they produce in the nervous system. They are defined by Orfila to be those which cause stupor, drowsiness, paralysis, or apoplexy and convulsions. Among their usual effects, in the various stages of their influence upon the body, may be mentioned numbness, coma, and sometimes delirium, cold and fetid perspiration, swelling of the neck, face, and sometimes of the whole body, dilatation of the veins, protrusion of the eyes, general prostration, chilliness and paralysis of the extremities, and, just preceding death in some instances, pain and convulsions. The narcotic-acrid poisons produce combinations of several of these symptoms. The effects of poisons differ widely in different persons, and are more or less distinctly marked according to the form, whether solid or liquid, in which the poisonous substance is administered. The symptoms are naturally varied too by the condition of the system, particularly of the stomach, when the poison is taken. It may be added here that the effects of poisons may be closely imitated by certain diseases, as, for example, by cholera. Rupture of various intestines, of the stomach, the duodenum, or the uterus may produce symptoms similar to those of irritant poisons. In seeking for the evidences of poison in a dead body, the first inquiry is as to the nature of the substance taken. It is a distinctive feature of the irritant poisons that they excite inflammation, in greater or less degree, in every part to which they are applied, and internally corrosions or perforations where

the poisonous matter rests longest. The inflammation varies in extent and intensity. It is usually observed in the mouth, throat, and stomach, but may reach through the whole length of the digestive tube. The membranes are of various degrees of redness, sometimes accompanied by dark patches of extravasated blood, and sometimes also by ulceration. The traces of narcotic poisons are not so evident. Dr. Christison says even that the marked appearances which they leave are insignificant. Certainly, it is not characteristic of this class of poisons, as is often supposed, that they induce putrefaction, or that the blood remains fluid. Often, however, the veins of the head are found gorged with blood, the lungs bear black and livid spots, and their texture is less dense. These same changes, both in the brain and in the nature of the blood, are produced by the narcotic-acrid poisons. For the purpose of charging innocent persons with murder, poisons have been in some instances injected after death. Orfila instituted experiments in this matter, and found that he could not reproduce in the dead body the appearances manifested by the living tissues. In the latter case, inflammation in graduated stages of intensity always attends the injury. But in his experiments there was always a perfectly defined line of demarcation between the points to which the poison was applied and those adjacent. In examination of the stomach, it is to be remembered that the vascularity or redness of this organ may arise as well from natural causes as from the influence of poisons. This appearance occurs, says an eminent author, in every variety of degree and character, under every circumstance of previous indisposition, and in situations where the most healthy aspect of the organ might be fairly inferred. Nor are marks of poisons to be confounded with those discolorations which may be produced by the liver and spleen. Ulcers and perforations have sometimes been wrongly attributed to the effects of poison. What is called the digestion of the stomach has often been mistaken for poison. In this condition of the organ its coats are rendered thinner and transparent, and sometimes the destruction of them advances even to perforation. These must be distinguished from those which are caused by corrosive poisons. The latter have clearly defined edges, and thick as the thickness of the coats which are pierced. These margins, too, are usually of a peculiar color, according to the poison employed; for example, yellow with nitric acid, brown or black with sulphuric acid and the alkalies, and orange with iodine. Finally, in a case of spontaneous erosion, there is generally a remarkable whiteness of the inner wall of the stomach; but in a case of poisoning there must be unequivocal signs of inflammation or of irritation.—In reference to the application of chemical tests, it may be remarked that poisons may be absorbed or decomposed, and in such cases it may be found by boiling the stomach and intestines, and subjecting the fluid to proper tests. Poisons which re-

main in the dead body may be affected by the chemical changes involved. By the ammonia disengaged during decay acids may be neutralized; and by the action of the animal matter the mineral salts may be decomposed. Soluble poisons, as oxalic acid, disappear; arsenic, opium, cantharides, and strychnia are not essentially changed. Our limits will not permit us to give the particular and specific evidence or indications of the action of different poisons; nor even to enumerate all those which have been considered in medico-legal practice, and are treated of in the various works on medical jurisprudence to which we have already referred. Nor can we indeed even enumerate all of these. But among the most important of the irritant class, or usually arranged in this class, are arsenic, the salts of mercury, lead, copper, and some other metals; sulphuric, nitric, oxalic, and some other acids. Of the narcotic class may be mentioned opium, prussic acid, strychnia, and the oils of cedar, tanzy, and savin; but some of this class also cause nervous irritation.—Insanity, in all its forms, is an important topic of medical jurisprudence. (See LUNACY.)

MEDIOL, a distinguished family of Florence, Italy. From an early period of Florentine history the Medici were conspicuous in the service of the republic. In 1351 Giovanni de' Medici, at the head of only 100 men, relieved the fortress of Scarperia by forcing his way through a Milanese army which was then besieging the place. A few years later Salvestro de' Medici acquired great reputation by his firm resistance to the tyranny of the nobles. In 1379 he was chosen chief magistrate, and effected important reforms in the government in spite of the commotions raised against him by the nobility. His son Veri held also a high rank in the state, and was very popular with the common people. The family were largely engaged in commerce, in which they had accumulated great wealth. The most successful merchant of them all was a second Giovanni de' Medici, who, after serving for many years as a member of the seignory and of the council of ten, was chosen, in Sept. and Oct. 1421, gonfaloniere, or chief magistrate, the term of the office being then two months. He died in 1428, leaving an immense estate to his two sons, Cosmo and Lorenzo.—Cosmo, or Cosimo, called **THE GREAT**, was born in 1389, and even in the lifetime of his father he had been deeply engaged in commerce, and had filled offices of state, having attained to a seat in the seignory in 1416. The death of his father made him the head of the family, and he soon became the leading man in the state, exercising a prodigious influence by his personal popularity, prudence, urbanity, and unbounded generosity. His power and that of his immediate descendants was of a very peculiar nature; it consisted in a sort of tacit influence voluntarily acquiesced in by the people, and not in any definite authority. The government of the republic continued to be directed by a council of ten and a gonfaloniere elected every two months. But the Medici

generally either assumed to themselves these offices, or nominated their friends and partisans to them, paying at the same time great deference to popular opinion, and, content with substantially controlling the state, avoiding all offensive display of power. Cosmo, however, in spite of his prudence and moderation, was at the outset opposed by a powerful party, headed by the Albizzi family; and in 1433 Rinaldo de' Albizzi carried the elections against him, and procured a decree banishing Cosmo for 10 years and his brother Lorenzo for 5 years. At the end of a year the party of the Medici again prevailed in Florence, repealed the sentence of banishment, and sent Rinaldo and his principal adherents into exile. The rest of Cosmo's life was passed in prosperity, and in the promotion of letters and arts, and the management of the foreign affairs of the republic. He continued to the last engaged in commerce, which he carried on by means of agents. His mercantile transactions seem to have been chiefly with the East through Alexandria, where an immensely lucrative trade existed in oriental productions, prior to the passage of the Portuguese around the cape of Good Hope. The banking houses which the Medici maintained by agents in the chief cities of Europe were also the source of vast profits; and a considerable revenue was drawn from their numerous farms and mines, especially the mines of alum, of which they had nearly the monopoly in Italy. Cosmo himself lived in a simple style, but spent vast sums of his own money in adorning the city with splendid public edifices. His wealth and influence ranked him with the most powerful princes of Italy, any of whom would have been glad to ally themselves by marriage with his family; but as such connections would have given rise among the Florentine people to unfavorable suspicions of his designs, he selected wives for his sons among the aristocracy of his native city—Piero, the eldest, marrying Lucretia Tornabuoni, while Giovanni, the youngest, espoused Cornelia de' Alessandri. Cosmo died Aug. 1, 1464. By a public decree shortly before his death he was honored with the title of *pater patriæ*, and the appellation was inscribed on his tomb. His son Giovanni died before him.—Piero, who succeeded Cosmo, was in such ill health as to be almost constantly confined to his bed. He was less popular than his father, and a powerful party, headed by Luca Pitti, the builder of the famous Pitti palace, and by other powerful nobles, was soon formed against him. Failing, however, to overthrow the Medici by peaceful measures, they attempted in 1466 to assassinate Piero, but their plot for this purpose was baffled by the vigilance of his son Lorenzo. The failure of this conspiracy strengthened the Medici, and their principal opponents were banished, with the exception of Pitti, who abandoned his own party and suddenly went over to that of the Medici, who now became the almost undisputed masters of the state. Piero died Dec. 3, 1469.

He was inferior in talent to his father Cosmo, but had conducted with skill and credit several important negotiations during his father's lifetime, and his subsequent direction of the affairs of state was marked by prudence and solidity of judgment. He was a munificent patron of letters and arts. "It is probable," says Tiraboschi, "that had Piero enjoyed better health and longer life, he might have done more for the interests of literature; but if he had only been known as the father of Lorenzo de' Medici, it would have been a sufficient title to the gratitude of posterity." Piero left two sons, Lorenzo and Giuliano.—LORENZO, surnamed THE MAGNIFICENT, was born Jan. 1, 1448. At an early age he gave striking indications of extraordinary talent, and the munificent disposition which afterward gave him a claim to the appellation of Magnificent was apparent in his childhood. He had rendered himself conspicuous before he arrived at manhood by his poetical talents, and by his penetration, courage, and good sense. He was tall and robust, with a dignified countenance and pleasing manners, but labored under some peculiar disadvantages. His sight was weak, his voice harsh, and he was totally devoid of the sense of smell. He received the first rudiments of education from Gentile d'Urbino, afterward bishop of Arezzo. In 1457 Christoforo Landino, an eminent professor of poetry and rhetoric, became his teacher; while in the Greek language, and in the philosophy of Aristotle, he was instructed by the learned Argyropulus, and in Platonism by Marsilio Ficino, for whom he contracted a friendship that lasted through life. When his domestic education was completed he visited the various courts of Italy, and his correspondence with his father during his absence shows that the latter had already learned to repose great confidence in the discretion and judgment of his son in political matters of the highest consequence. The share taken by Lorenzo in defeating the conspiracy headed by Lucca Pitti, and the lenity and magnanimity with which he treated the conspirators, extended his reputation throughout Italy. On June 4, 1469, he was married to Clarice Orsini, of the noble and powerful Roman family of that name. Their nuptials were celebrated with splendid exhibitions of military spectacles and other pageants. On the day after the death of his father in the same year, Lorenzo was waited upon by many of the principal inhabitants of Florence, who requested that he would take upon himself the administration and care of the republic in the same manner as his father and grandfather had before done. In 1471 he was sent to Rome at the head of a magnificent embassy to congratulate Sixtus IV. on his elevation to the papacy. The pope on this occasion formally invested him with the office of treasurer of the holy see. The friendship of Sixtus, however, was not of long continuance. He undertook in 1474 the conquest of the city of Castello, against which place he sent an army. As Castello bordered the territory of Florence, and

its ruler Niccolo Vitelle was a personal friend of Lorenzo, Florence lent some assistance to its defence, which, though ultimately unsuccessful, was so vigorous and protracted as to cause the pope great expense and vexation, which he attributed chiefly to Lorenzo, against whom he conceived a violent hatred. An additional motive of resentment was found in the fact that Lorenzo had lately effected an alliance between Florence, Venice, and Milan, for the purpose of checking the ambitious projects of the pope and protecting the independence of the minor states of Italy. Regarding the Medici as the chief obstacle to his aggrandizement, Sixtus zealously strove to destroy their power, and he is even accused by many historians of having instigated a conspiracy for the assassination of Lorenzo and his brother Giuliano. Into this plot entered the cardinal Riario, the archbishop of Pisa, several priests, and Francesco and Giacompo de' Pazzi, of a noble Florentine family hostile to the Medici. The attempt was made during divine service in the church of the Reparata, on Sunday, April 26. The signal agreed upon was the elevation of the host, at which moment Francesco de' Pazzi and another conspirator named Bandini stabbed Giuliano, and instantly killed him. Two priests at the same instant attacked Lorenzo, but only succeeded in giving him a slight wound in the neck. He defended himself with vigor, and was presently surrounded by his friends, who escorted him home after putting to death all the conspirators within reach except a few who were saved by the generous interposition of Lorenzo himself. Meantime an unsuccessful attempt had been made to seize the government palace by the archbishop of Pisa, who was taken prisoner by the magistrates, and summarily hanged from its windows, together with Francesco and several others of the Pazzi, of which family the only one who escaped the popular fury received shelter in the house of Lorenzo. Bandini, the murderer of Giuliano, escaped from the city and from Italy, and took refuge in Constantinople; but the sultan ordered him to be seized and sent in chains to Florence, because, as he declared, of the respect which he had for the character of Lorenzo de' Medici. The ill success of this flagitious conspiracy did not mitigate the wrath of Sixtus against the Medici, and he forthwith issued a bull excommunicating Lorenzo and the magistrates, and suspending the entire Florentine clergy from their functions on account of the execution of the archbishop of Pisa. He also, in conjunction with the king of Naples, made open war upon the republic, offering, however, to conclude peace upon the condition that Lorenzo should be banished from Florence, or delivered into their hands. As the resources of Florence were inadequate to long maintain a contest with two such powerful enemies, Lorenzo, perceiving that the war was waged against him personally, took the extraordinary resolution of proceeding to Naples and putting himself in the king's power. He accordingly went thither, and was received with great distinction.

His personal influence had such an effect upon the king of Naples, that, in spite of the utmost efforts of the pope, Lorenzo in the course of three months converted him from an enemy to a warm friend, and returned to Florence, bringing with him a treaty of peace and alliance with Naples. Peace with the pope followed soon after. Lorenzo now began to take measures for securing the peace of Italy by establishing a balance of power in the peninsula, of which Florence was to be the political centre. He also proposed and persuaded the people to agree to the institution of a permanent senate, nominated by himself, to govern the republic instead of the democratic councils to whom the supreme power had been previously intrusted. A second attempt to assassinate him was made in the church of the Carmeli, May 31, 1481. The assassins were seized before they could execute their purpose, but the attempt furnished Lorenzo with a convenient excuse for surrounding himself with a body guard. His inveterate enemy Sixtus IV. died in 1485, and was succeeded by Innocent VIII., who was friendly to Lorenzo, and in a short time made the Florentine his most intimate confidant, and thus opened to the Medici the dignities and emoluments of the church by which the family afterward so much profited. The alliance of the pontiff augmented still more the influence of Lorenzo upon the affairs of Italy, which was now in a more prosperous condition than it had been for 1,000 years past, while Florence itself had reached the highest pitch of power and opulence to which it ever attained. "This extraordinary felicity of Italy," says the historian Guicciardini, "several circumstances contributed to preserve; but among the rest, no small share of it was by general consent ascribed to the industry and the virtue of Lorenzo de' Medici; a citizen who rose so far beyond the mediocrity of a private station, that he regulated by his counsels the affairs of Florence, then more important by its situation, by the genius of its inhabitants, and the promptitude of its resources, than by the extent of its dominions; and who, having attained the implicit confidence of the Roman pontiff, rendered his name great and his authority important throughout Italy." Lorenzo's attention to public affairs had obliged him to neglect his own, and he became so involved by expenditures for political purposes that in 1490 the republic granted him a sum to pay his debts, of so large an amount that Hallam says she "disgracefully screened the bankruptcy of the Medici by her own." At this time he abandoned commerce, which his family had pursued for so many generations. In the beginning of 1492 he was attacked by a strange species of fever which baffled the skill of the physicians, and of which he died on April 8. He left three sons, of whom Piero, the eldest, was born Feb. 15, 1471; Giovanni, the second, who had been made a cardinal at the age of 18, and became afterward pope under the title of Leo X., was born Dec. 11, 1475; and Giuliano, the youngest, who became duke of Nemours, was

born in 1478. Lorenzo was eminent not only as a statesman, but as a poet and scholar. Among his most intimate friends were the poets Politiano and Pulci. He was a munificent patron of authors and artists, and spent vast sums in erecting public edifices and in establishing schools and libraries. He reestablished the university of Pisa, and greatly enlarged the famous Laurentian library at Florence, which derives its name from him, and which was founded by his grandfather Cosmo. See Roscoe's "Life of Lorenzo de' Medici" (2 vols. 4to., London, 1798, the 10th and best edition of which forms a volume of Bohn's "Standard Library" (London, 1851).—PIERRO DE' MEDICI, the successor of Lorenzo, had much of the talent without the prudence of his father. His ambition and temerity involved Florence in war with Charles VIII. of France, and led to his own expulsion from the city in 1494, and to the occupation of Florence by the French army shortly afterward. After an exile of 10 years, during which he made repeated though futile attempts to regain his authority in Florence, he entered the service of France, and was present at the great defeat of the French army by Gonsalvo de Cordova on the banks of the Garigliano, in which river he was drowned while endeavoring to escape from the pursuit of the Spaniards. By his death his second brother, Cardinal de' Medici, became the head of the family. In 1512, partly by policy, partly by force, he effected the restoration of the Medici to Florence, and shortly afterward, March 11, 1513, was himself elected pope. (See Leo X.; vol. x. p. 456.) He intrusted the direction of Florentine affairs to his younger brother GIULIANO, who, having more taste and capacity for literature than for politics, soon resigned his authority into the hands of his nephew Lorenzo, the son of the Piero who fell at Garigliano, and retiring to Rome became commander-in-chief of the papal troops. Having married Filiberta of Savoy, a descendant of the house of Bourbon, he was made duke of Nemours by Francis I. of France. He died at Florence in March, 1516. He left a natural son, IPPOLITO, who became a cardinal with an immense revenue, which enabled him, without territories and without subjects, to maintain at Bologna a court far more splendid than that of any Italian potentate. He was, says Roscoe, "at once the patron, the companion, and the rival of all the poets, the musicians, and the wits of his time. His associates and attendants, all of whom could boast of some peculiar merit or distinction which had entitled them to his notice, generally formed a body of 800 persons." He died while yet young from poison administered by one of his domestics.—LORENZO II., after the resignation of Giuliano, governed Florence for some time under the orders of Leo X. He made himself by force of arms duke of Urbino in 1516, and in 1518 married Magdeleine de Boulogne, of the royal house of France. He died in the following year, a few days after the birth of his famous daughter Catherine de' Medici, afterward queen of France. Prior

to his marriage the duke of Urbino had an illegitimate son named ALESSANDRO, whose mother was an African slave. The paternity of Alessandro has also been attributed to Pope Clement VII., who was himself an illegitimate son of Giuliano, the brother of Lorenzo the Magnificent. It is certain that Alessandro was in high favor with the pontiff, who, on the death of Lorenzo II. without a legitimate male heir, and the consequent failure of the descendants of Cosmo the Great, brought him forward in order to prevent the power of the family from passing into the hands of a collateral branch descended from a brother of Cosmo. He accordingly availed himself of the dissensions of the Florentines, and in 1532, with the assistance of the emperor and the king of France, he compelled the republic to receive Alessandro as its ruler, with the title of duke. He proved, however, to be a licentious tyrant, and was assassinated in 1536 by Lorenzino, a member of the collateral branch of the family. The citizens assembled on this event, and invested Cosmo DE' MEDICI, the cousin of Lorenzino, with the sovereignty under the title of the chief of the republic, which he afterward exchanged for that of grand duke. He became the progenitor of a line of grand dukes, 6 in number, who ruled Tuscany till 1737, when the main line of the Medici family became extinct.

MEDICI, MARIA DE'. See MARIA DE' MEDICI.

MEDICINE, the art and science of curing disease. The practice of medicine must have everywhere arisen from the accidents and infirmities to which mankind are liable. Some rude appliances to wounds and injuries, some equally rude observances in cases of internal disease, are common among the most barbarous people. The idea that disease is caused by the anger of superior and invisible beings placed its treatment in the hands of the priests, and the same idea caused that treatment to consist mainly of superstitious rites. In what beyond this consisted the medicine of the Egyptians, the Hindoos, &c., is a matter of conjecture only. In Greece as elsewhere the early history of medicine is involved in darkness, and it is idle to guess how much truth is contained in the fables concerning Chiron and his pupil Æsculapius, or the sons of the latter, the Homeric heroes Machaon and Podalirius. We know, however, that the temples of Æsculapius were from an early period the resort of the sick, who submitted themselves to the regulations of the Asclepiads, the priests of the temples, and that these priests must have thus had large opportunities for the study of disease. It was common among those who were cured to deposit in the temple a votive tablet, on which was inscribed some account of the case and of the remedies by which it was relieved; but if the tablets which have come down to us are fair samples, but little information could have been communicated in this way. Much more must have been due to the education in the temple, to personal observation,

and to the restless and inquiring spirit which animated the early Greeks. But the temples of Æsculapius are not the only source to which the origin of scientific medicine is to be traced; in the schools of philosophy some attention was always paid to the healing art as a branch of general education. When the school of Pythagoras was broken up, and his disciples dispersed, some of them attended to the practice of medicine; and unlike the Asclepiads, who confined their consultations to the temples, the Pythagoreans visited the sick at their residences. Of the extent of their knowledge or the value of their treatment we have no means of forming a judgment. Even at this period it seems that there was still another class, the charlatans, who, without any pretension to education, offered their nostrums for sale in the market place. Beside the temples of Æsculapius and the schools of philosophy, the gymnasia undoubtedly contributed to form the earlier physicians. The gymnasiarchs directed the regimen of those who resorted to the gymnasia; they acquired practical skill in the treatment of the injuries to which their pupils were liable; they set fractures, reduced dislocations, directed frictions, dressings, &c.—In these various ways medicine had already made sensible progress when Hippocrates (born in Cos about 460 B. C.) collected the scattered knowledge of his time, and added to it by his own genius and observation. Of the numerous works ascribed to Hippocrates, enough are decided to be genuine by the unanimous consent of the learned to justify the veneration in which he has always been held as the father of rational medicine. Of anatomy the notions of Hippocrates were crude and limited, and must have been derived solely from the inspection of animals, since the religious prejudices of the ancients prevented the dissection of the human body, until a period long posterior to the one of which we speak. His physiology is on a level with his anatomy. The glands are spongy bodies destined to absorb moisture from the neighboring parts, and the brain, the largest of the glands, draws the vapors from the whole interior of the body. The use of the muscles is to cover the bones, &c. (Renouard, *Histoire de la médecine*.) The body itself is composed of the 4 elements differently combined in different individuals, and derived from them we have the 4 humors of the body, blood, phlegm, bile, and black bile, from which again are derived the 4 temperaments. Disease consists in a disordered condition of the fluids; these are subject to coction, which when complete terminates in a critical evacuation, the localization of the disease, and the formation of a critical abscess, the occurrence of erysipelas, &c. When coction could not take place the disease was mortal. Crisis was apt to occur on certain days, hence termed critical. He speaks of a principle which he terms nature (*φύσις*), which influences every part of the human frame, superintends all its actions, promotes those that are beneficial, and represses those that are injurious; the great ob-

ject of the physician was to watch the operation of this principle, to aid or restrain it, rarely to counteract it. He regarded acute diseases alone as the subject of treatment; chronic affections were esteemed beyond the resources of art. The great merit of Hippocrates lies not in his theories, but in his descriptions of disease; and when we bear in mind the limited scope of his methods and his ignorance of anatomy and physiology, we cannot but admire the sagacity and fidelity of his observations.—Not long after Hippocrates, Praxagoras of Cos, the last of the Asclepiadae whose name is mentioned in the history of medicine, and probably belonging himself to the family of Hippocrates, observed the relation which exists between the pulse and the general condition of the system. None of his writings have been preserved. Aristotle was the son of a physician, and probably in the earlier part of his life himself practised medicine; his knowledge of the structure of the body, derived entirely from the dissection of animals, was far in advance of that of his contemporaries; and he laid so widely the foundations of comparative anatomy, that for ages little that was new was added to what he had written. He distinguishes between the nutritive, the sensitive, the motive, and the intellectual faculties. The first is common to plants and animals to every thing which lives and dies; the last is confined to a very few species of animals. The 3 first faculties reside in every part of the body; the intellect alone has a special seat. Where this is he nowhere expressly states, but it is evident from a variety of passages that he placed it in the heart. He speaks of the greater size of the brain in mankind, states that it is composed of two lobes and of the cerebellum, and mentions the ventricles. Of the nervous system he was ignorant, confounding the nerves with the tendons. Of the lungs his account is reasonably correct. The blood vessels as well as the nerves he derives from the heart, which alone contains blood of itself, that of the lungs being contained in the vessels connected with the heart. The blood is the most important of the fluids, and is necessary to life; deprived of it to a slight extent, the animal faints, to a greater dies, while its attenuation and alteration give rise to disease.—Soon after its foundation, Alexandria, under the fostering care of the Ptolemies, became the centre of the science and learning of the time. This was especially the case with regard to medicine; the formation of the Alexandrian library at a time when books were rare and expensive, the personal support of the Ptolemies, the new drugs which commerce brought from distant countries, and above all the authorization of human dissections, gave a great impulse to medical science. Unfortunately the works of the great men who illustrated the Alexandrian school have entirely perished, and we can only judge of them by the reports which are scattered through the writings of Aretæus, Celsus, Pliny, Galen, &c. Of the earlier members of the Alexandrian school, Herophilus

and Erasistratus were the most distinguished. The former was familiar with the lacteal vessels and their connection with the mesenteric glands; the muscles were no longer a mere covering for the bones, but their proper office was attributed to them. Erasistratus was acquainted with the functions of the nerves, and is said to have invented the catheter; while Ammonius, another member of the Alexandrian school, invented an instrument for the crushing of stone in the bladder, thus perhaps anticipating an improvement of our own day. With Herophilus and Erasistratus the zeal for anatomy seems to have died out; between them and himself, a period of 500 years, Galen enumerates 5 or 6 physicians only who occupied themselves with human dissections.—Until the rise of the Alexandrian school, dogmatism or rationalism, fortified by the authority of Hippocrates, had been the prevailing system. The dogmatists maintained that in order to treat disease we must be acquainted with its occult as well as exciting causes, and with the natural actions of the body, as concoction, nutrition, &c. To this Philinus of Cos and Serapion of Alexandria replied that the occult causes of the dogmatist depended entirely upon hypothetical opinions; that the minute motions and changes of the internal parts were beyond our observation; that even where the cause of a disease was known, it by no means followed that such knowledge led to a remedy; and that close observation of disease and experience of the effects of remedies in its treatment were the only safe guides to medical practice. The new doctrine, or empiricism as it was termed, long divided medical opinion with dogmatism, though the writings of its advocates have entirely perished, and we are acquainted with their views mainly through the summary given by Celsus. About 150 years after the origin of empiricism, Asclepiades of Bithynia, at first an eminent rhetorician, and as such honored with the intimacy of Cicero, began to practise medicine at Rome. A philosopher rather than a physician, he was a follower of Epicurus; and on the theories of his master he founded a new medical doctrine which, aided by the popularity of the Epicurean philosophy, as well as by its novelty and simplicity, soon found numerous followers. According to Asclepiades, the human body is permeated in every direction by pores through which at all times atoms varying in form and volume are constantly passing. Health consists in the symmetry between the pores and the atoms which pass through them. Disease is an obstruction of the pores or an irregularity in the distribution of the atoms. This theory was further developed by Themison of Laodicea, a pupil of Asclepiades, who made all diseases depend upon constriction or relaxation, or upon a third and mixed condition, while all remedies were divided into astringents and relaxants. Asclepiades, it is said, was the first to divide diseases into the two great classes of acute and chronic. While the dogmatists made the fluids

the prime seat of disease, and ascribed the origin of all maladies to some alteration in them, the methodists on the other hand thought the solids were first affected, and that the derangement of the humors was but secondary; and the dispute about the humoral pathology and solidism, thus originated, has under various forms continued to our own time.—For 600 years, according to Pliny, Rome had no physicians; not that no attempt was there made to cure diseases, but that these attempts consisted mainly in superstitious observances. Thus, according to Livy, following the advice of the Sibylline books, pestilence was repeatedly stayed at Rome by erecting a temple to Apollo or to Æsculapius, by celebrating public games, or by the dictator driving a nail into the capitol; and Cato the Censor trusted to simples with charms and incantations. When intercourse with Greece became common, Grecian philosophy and science were transplanted to Rome. As has been already mentioned, Asclepiades was the friend of Cicero, and Cæsar when he was taken by the pirates was accompanied by his physician. On attaining supreme power, Cæsar decreed that all physicians at Rome should enjoy the privileges of citizenship. After the names of Asclepiades and Themison, that of Soranus occurs prominently among those practising medicine at Rome; there were probably 3 physicians of this name, but the most celebrated was a Greek educated at Alexandria and settled at Rome; his writings have perished, unless, as some have supposed, those of Cœlius Aurelianus are a translation of them. C. Aurelianus is said to have been a native of Numidia, and probably flourished early in the 2d century. Of numerous works of which he was the author, that on acute and chronic diseases is alone preserved. It is written in barbarous Latin, but in its description of disease is a great advance on earlier authors. C. Aurelianus, like Soranus, belonged to the methodic sect, and is its principal exponent. Of the few Latin medical authors, Celsus is the chief. As is the case with so many of the physicians of antiquity, we know nothing of his personal history, and are uncertain indeed whether he ever practised medicine. He would appear to have lived toward the termination of the 1st century, and to have written voluminous treatises on a variety of subjects, on architecture, rhetoric, philosophy, &c., all of which have perished. His book *De Medicina* is a digest of what was known to the ancients on the subject, and shows the great progress which medicine had made in consequence of the labors of the anatomists of Alexandria. Celsus treats of most of the great operations of surgery, of the operations for stone and hernia, of wounds of the intestines, of catarrh; he gives directions for the use of the catheter, speaks of the trephine in injuries of the brain, and of the use of the ligature in divided or lacerated blood vessels, in varices, and in hæmorrhoids. The name of Andromachus, a native of Crete and physician to Nero,

has come down to us as the inventor of certain polypharmaceutical compounds, one of which, the theriac, containing the dried flesh of vipera, with 60 other ingredients, was retained in the pharmacopœias of the last century; and he is likewise the first to whom was given the title of archiater. Probably contemporary with Cœlius Aurelianus was Aretæus of Cappadocia; we know nothing of him but his birthplace; he has left a treatise on diseases remarkable for accurate and spirited description, and which is one of the most valuable of the medical works of antiquity. We now come to Galen (born in Pergamum, A. D. 180), who after Hippocrates has had a far wider share of renown than any other physician; for more than 12 centuries his authority reigned supreme in the schools; even a fact was disputed if it was against the authority of Galen. He adopted the Hippocratic theory of the 4 elements, the 4 humors, and the 4 qualities, elaborating and refining upon them at great length and with great subtlety, and making them the groundwork of his doctrines. Beside the solids and the fluids, he assumed a third principle, the spirits, as entering into our composition. These spirits were of 3 kinds: the natural spirits, derived from the venous blood; the vital spirits, formed in the heart by the action of the air we breathe upon the natural spirits, and which are driven through the arteries; and the animal spirits, formed in the brain from the vital spirits. He also supposed the human soul to be composed of 3 parts: a vegetative, residing in the liver; an irascible, in the heart; and a rational, having its seat in the brain. The most valuable of the works of Galen are those in which he treats of anatomy and physiology. He appears to have dissected animals only, and he recommends students to visit Alexandria, where they could study from the human skeleton. Considering the narrowness of his resources, his descriptions are wonderfully correct, and they comprehend all that was known of anatomy until the time of Vesalius. Another author, who lived probably in the latter part of the 2d century, Dioscorides, for many centuries shared the authority of Galen. He has left a work on the materia medica which comprises all that was known to the ancients upon the subject; its arrangement is bad, and the descriptions of the articles so vague that many of them can no longer be recognized with certainty; yet imperfect as it may be, it was for 1,500 years a standard treatise.—From the time of Galen medicine began to participate in the decline which had already overtaken art and literature. Dissections were no longer made; the earlier Christians had as great a horror of profaning the dead body as the pagans, and medical writers, appearing at rare intervals, contented themselves mainly with abridging or copying the works of Galen. Oribasius in the 4th century, Ætius in the 5th, Alexander Trallianus and Paulus Ægineta in the 6th, all wrote in Greek, and were all zealous Galenists. It is but just to observe that Paulus seems to have

been fuller than his originals in the description of surgical diseases and operations. It was only when medicine already tended toward its decline that it became legally organized. In the pagan world every one practised at his will, making his way by such qualities as he possessed. The injury done by quackery and imposture led finally to a remedy. Under the Christian emperors every town of a certain size had its archiateres (chief physicians), and no one could practise medicine without having undergone an examination by them. They were paid by the state, and in return were bound to attend the poor gratuitously. In a number of the principal towns medical schools were established, in which the professors and lecturers received a regular salary. The archiateres of the emperors had the title of count or duke, and ranked with the principal officers of state. —Hospitals and dispensaries owe their origin to Christianity; the pagans appear to have had no analogous institutions. The first hospital would seem to have been founded at Jerusalem by St. Paula toward the end of the 4th century, and the example once given was soon followed by the pious, the powerful, and the wealthy.—While the western empire had sunk into barbarism, and the eastern, sadly limited, was struggling for existence, medical science found refuge for a time among the Arabians. Excepting on two points, they contributed but little or nothing to its advancement; but Rhazes, Ali Abbas, Avicenna, Albucasis, with the Spanish Saracens Avenzoar and Averrhoes, were all voluminous writers. Their writings consist mainly of compilations from the Greek authors, and chiefly from Galen, whose subtleties and refinements were suited to their genius; yet the "Canon" of Avicenna was for several centuries the received text book in the medical schools of both the Arabians and Europeans; and all the knowledge Europe had of the Greek authors was derived from the translations of the Arabs. In two particulars, as was mentioned, the writings of the Arabians are of high interest: 1. In them we get the earliest clear account of the existence of eruptive fevers; these were divided by them into two forms, *variola* (small pox) and *morbilli* (the little pest), the latter including measles, scarlet fever, and probably other non-vesicular eruptions. It is impossible to determine whether these diseases now appeared for the first time, or whether, after having for ages been confined to some obscure corner of the East, they were now first distributed over the world by the conquests and commerce of the Saracens. It certainly seems very unlikely that a disease so well marked and leaving such permanent traces as the small pox could have previously existed in Greece or Rome without some account of it having been transmitted to us. 2. Not only do we derive from the Arabians a number of our milder purgatives, cassia, manna, senna, rhubarb, together with tamarinds, camphor, &c., but in their pursuit of alchemy they pro-

duced distilled liquors, some of the metallic salts, and many new pharmaceutic preparations, and laid the foundations of a science which has been of the most essential service to medicine. —As order again began to emerge from the chaos of barbarism which succeeded the fall of the western Roman empire, monks and priests became the principal physicians, and a little medicine was taught in some of the monasteries; for a long time the Benedictine monks of Monte Cassino enjoyed in this respect an extended reputation. From the 9th to the 18th century the Jews, acquiring in their commerce with the Saracens such knowledge as was possessed by the latter, became celebrated as physicians; and as such, despite the laws which forbade them to administer remedies to Christians, obtained access to courts and even to the palace of the Roman pontiff. One small town affords a glimmer of light during the darkness of this period. The school of Salerno is said to have been founded about the time of the destruction of the Alexandrian library by the Saracens. Toward the end of the 8th century it had attained reputation, and from the 10th to the 18th was at the height of its celebrity. The *Regimen Sanitatis Salerni*, the dietetic precepts of the school of Salerno, composed by John of Milan for the use of Robert duke of Normandy, the son of William the Conqueror, has been frequently republished and commentated. The most celebrated member of this school was Constantinus Africanus, who, driven from his native country as a sorcerer, for a time taught at Salerno. His works, which are numerous, are translations from the Arabic, written in barbarous Latin. In the course of the 18th century Frederic II. published an edict that no one should practise medicine in the kingdom of Naples until he had been examined by the faculty of Salerno. The candidate, after completing his course of studies, was examined on the Therapeutics of Galen, the first book of Avicenna, and the Aphorisms of Hippocrates. He afterward swore to be pure in his life, to be submissive to the laws, to attend the poor gratuitously, and not to share the profits of the apothecary. He then received a diploma, but for the first year was compelled to practise under the superintendence of an older physician.—About the year 1815 Mondini, a professor in the university of Bologna, dissected the bodies of two females; he afterward published an anatomical description of the body, illustrated with woodcuts, which for the next 800 years was used as a text book in the Italian universities. His merit consists mainly in the boldness of his undertaking, as his anatomy was not much in advance of that of Galen. He did not open the cranium for fear of committing a mortal sin. Before the year 1500 human dissections were prosecuted at Bologna, Padua, and Pavia. Toward the commencement of the 15th century Du Bois, or Sylvius, as his name was Latinized, used the human body in his demonstrations at Paris as often as it could be procured.

Galen was still looked up to as an indisputable authority; and when the results of dissection did not coincide with his descriptions, they were looked upon as exceptions to the general rule, or as evidence of the degeneracy of the human race. Such was the state of things when, about the year 1543, Vesalius, professor of anatomy in the university of Padua, published his great work on anatomy, in which he pointed out the errors of Galen, and maintained that his descriptions were taken, not from human dissections, but from those of apes. The age was one of anatomical discovery, and Columbus, the successor of Vesalius at Padua, Eustachius at Rome, and Fallopius, confirmed and increased the discoveries of Vesalius. The prejudices against human dissections were mitigated, subjects became comparatively abundant, and printing and engraving served to spread abroad and perpetuate the discoveries that were made. —After the fall of Constantinople, learned Greeks escaping from the captured city carried a knowledge of their language and literature to the western world. Previous to this date the Greek medical writers had been read only through the medium of faulty Arabic translations; but medical men now availed themselves of this new source of information, and translations of Galen, Hippocrates, Dioscorides, &c., were made directly from the Greek. Thomas Linacre, physician to Henry VIII. and to Mary, distinguished himself in this career; he established professorships at Oxford and Cambridge for illustrating the works of Hippocrates and Galen, and laid the foundations of the royal college of physicians at London. Among those distinguished in the same path were Mercurialis, Foëx, and J. Fernel; and the attention of physicians as of the learned throughout Christendom was directed to rescuing and illustrating the remains of antiquity rather than to original research. —While medicine was thus recovering the ground it had lost, surgery too was improving. Physicians in the middle ages being invariably priests, whom a canon of the church forbids to shed blood, surgical operations commonly fell into the hands of an inferior and ignorant class of barber surgeons, who frequently were itinerants. Gradually matters improved, the clerical physicians occasionally operated, while the barber surgeon struggled to raise himself to a higher rank. Gui de Chauliac, a learned priest who published about the year 1363 the earliest modern work on surgery, operated himself; while in the 16th century the great anatomists Vesalius, Fallopius, &c., were likewise distinguished surgeons. It was from Ambrose Paré, however, who commenced his career as a barber surgeon, that surgery received its greatest impulse. At that period wounds received from firearms were considered poisonous, and it was customary on this account to cauterize their track with boiling oil. In 1586, on one occasion, while serving as surgeon with the French army in Provence, Paré's supply of oil failed him. He could not sleep for anxiety,

but in the morning he found that those who had not been cauterized were doing better than those who had been cauterized, and the observation thus made soon led to a revolution in practice. The application of the ligature instead of the actual cautery to restrain hæmorrhage after amputations was another of his discoveries. —While the authority of the Galenists was disputed by the anatomists on matters of fact, his opinions were attacked by a new school of physicians, who were the offshoot of the prevailing study of alchemy. Of this school Paracelsus obtained the greatest notoriety. He publicly burned the works of Galen and Avicenna at Basel, but had nothing to substitute for them but wild and incoherent speculations. Perhaps it was partly owing to the growing spirit of independent observation that we first hear during the 15th century of a number of new diseases. Whooping cough, scurvy, the sweating sickness, and syphilis were now first described. Of scurvy we must believe that the causes which produce it at present must have produced it from all time; and that if it seldom occurred in ancient times, it must have been because of the different modes of living and from the short duration of the voyages. With syphilis the case is different; the theory of the American origin of the disease is now shown to be destitute of foundation, and whether it had existed obscurely for a long time, or whether it arose, as some think, from a degeneration of the leprosy so prevalent in the middle ages, its sudden explosion at Naples in 1493 and its rapid spread throughout Europe are equally unaccountable. —The great anatomists of the 16th century had paved the way for the discovery of the circulation of the blood; Servetus had proclaimed the lesser circulation through the lungs; the valves of the heart, of the aorta, and of the veins were known; it was proved by experiments on living animals that when an artery was tied the blood no longer flowed, and the pulse ceased on the side most distant from the heart; that when a vein was tied it swelled below the ligature, while it became empty on the side toward the heart; and yet the last step was not made. At length William Harvey, after having for 12 years taught the circulation of the blood in his lectures, in 1628 published his doctrine to the world; and though meeting at first with opposition from some of the older members of the profession, it made rapid progress and was universally adopted during the lifetime of its discoverer. In 1661 Malpighi by the aid of the microscope showed the course of the globules of the blood in the smaller vessels, and 80 years later Leeuwenhoek was able to follow the circulation into the minutest capillaries. The true theory of respiration soon followed the discovery of the circulation. The ancients taught that the minute bronchial tubes inoculated with the pulmonary veins, and that the air thus found its way into the heart. In 1661 Malpighi demonstrated the vesicular substance of the lungs, and about the same time Borelli, Haller, and others showed the

mechanism by which respiration is accomplished. In 1622 Gaspard Asselli, professor of anatomy at Milan, discovered the lacteal vessels; and 25 years later Jean Pecquet demonstrated the reservoir which bears his name, together with the thoracic duct from its commencement to its termination in the left subclavian. The lymphatic system, the nerves, the brain, and the organs of special sense were all studied with care by observers whose names we have not space to enumerate. In 1747 Haller published his *Primæ Lineæ Physiologia*, and 10 years later his *Elementa Physiologia Corporis Humani*; and from this period physiology had a distinct existence as a science.—In the mean time the materia medica had been enriched by a number of new articles. The chemists had introduced a variety of metallic and alkaline salts, and the new world had yielded guaiacum, sarsaparilla, ipecacuanha, &c.; but two remedies from their importance require a more special notice. On the first appearance of syphilis the surgeons had attacked it by means of mercurial frictions, and with success; but their employment in numerous instances was attended by such terrible consequences, that they gradually fell into disuse. Paracelsus had employed mercury internally, but in the hands of such a practitioner it could rarely be productive of other than mischief; the Galenists condemned its use, and the chemical physicians gave it rarely and secretly. Gradually it again came into favor, and in 1750 Van Swieten, the physician of Maria Theresa, directed all the cases of syphilis in the military and civil hospitals of the Austrian empire to be treated with small doses of corrosive sublimate in solution, and the practice soon became common throughout Europe. The ancients, with whom malarious diseases were common, had no specific means of arresting their attack; even mild intermittents often continued for an indefinite time, and finally induced organic changes and dropsy. In 1639 Peruvian bark is said to have been introduced into Spain by the countess of Cinchon; and though the extravagance of its price, the adulterations it sometimes met with, and its nauseousness were obstacles to its success, its use soon became common throughout Europe.—As chemistry, from vain search after the philosopher's stone or the *elixir vita*, began to assume the aspect of a science, it influenced more markedly the prevailing medical doctrines. Francis de Leboë or Sylvius, a Fleming called to the professorship of practical medicine in 1658, was the first to present a chemical theory of the actions of the animal economy. According to this theory, digestion and nutrition were the consequence of specific fermentations, in which the saliva, the pancreatic juice, and the bile take part. Fevers were produced by other fermentations caused by a vicious bile or lymph. Certain of the humors were naturally acid, others alkaline; in a state of health these were in equilibrium, but disease was consequent upon the predominance of one or the other. This

doctrine, more or less modified, had many followers, and for a time was prevalent both upon the continent and in England. Willis and Thomas Sydenham may be ranked among the iatro-chemists; but Sydenham is much the more remarkable for the careful and conscientious manner in which, uninfluenced by theory, he gave himself up to the observation of disease.—While the chemical school was taking form at the north, in Italy the progress of physical science was turning the attention of theoretic physicians in a new direction. Alfonso Borelli, a profound mathematician, was the originator of what has been termed the iatro-mathematical school. In the first part of his work *De Motu Animalium* he applies the received principles of physics to the subject of muscular action, treats of the various attitudes and modes of progression of men and animals, of walking, running, leaping, flying, swimming, and enters into learned and curious calculations of the amount of force which is expended in particular acts. In the 2d part he treats of the internal movements, of those of the heart, of the blood in the vessels, and of the action of the intestinal canal; the whole body was regarded as a machine, and the laws of mechanics, of hydraulics and hydrostatics, were rigidly applied to it. As an instance of the futile but elaborate calculations into which the mathematical physicians were led, Borelli calculates that the heart at each contraction overcomes a weight of 180,000 lbs. The physiology of the mathematical school had its influence upon their pathology; and the terms derivation, revulsion, lentor, obstruction, resolution, &c., all founded on physical principles, were universally used. The mathematical school had many and eminent followers throughout Europe—in Great Britain, Pitcairn, Freind the historian of medicine, and Mead; in Holland and Germany, Boerhaave and Jean Bernoulli; in France, Sauvages, the eminent and learned nosologist, and Senac, the physician of Louis XIV. Hermann Boerhaave, professor of medicine at Leyden, was possessed of great talent and immense learning, and was an accurate observer and a sagacious practitioner. He was one of the first to devote himself to clinical teaching, and he was fortunate in the devotion of such pupils as Van Swieten and Haller. Unfortunately for his permanent reputation, he lived in an age of transition, and his system, generally received during his lifetime, scarce survived its author. Jean Senac, another of the mathematical physicians, to whom Morgagni applies the epithet of "great," published a book on diseases of the heart, which has only been rendered obsolete by the introduction of the new methods of auscultation and percussion.—While the chemical and mathematical physicians were reducing the actions of the living body to the laws which govern inert matter, a wholly opposite tendency manifested itself in Germany. Previously indeed Van Helmont, a mystic and alchemist rather than a physician, in accounting for the vital operations, had introduced

what he termed the *archæus*, now a chemical ferment and now an intelligent being, as a controlling power; but his opinions found no followers, and only influenced indirectly the progress of medicine. George Ernest Stahl, a great chemist as well as physician, appointed professor of medicine in the university of Halle in 1694, was the author of the new system. According to Stahl the *anima* (the soul) is the great motor and directing principle of the human body. It exercises a recuperative and superintending influence, guards against injuries, or when they occur takes the best means of repairing them; it is the common source of all motion, of all secretion, of all the vital actions. In showing the insufficiency of the known chemical or physical forces to account for the vital actions, Stahl is happy and ingenious; but in his subtle disquisitions on his own agent, he becomes confused and unintelligible. He has the merit of showing much more clearly than had hitherto been done the influence which the mind exerts over the body. Stahl's opinions, contrary to most theories, exerted a controlling influence over his medical practice, reducing the office of the physician to that of watching and forwarding the operations that nature undertakes for her own relief; while his doctrines, set forth with great logical subtlety, at a time when metaphysical speculations were in vogue, though they found few direct followers, yet had a large influence on the minds of the profession. Friedrich Hoffmann, a fellow professor with Stahl at Halle, was a voluminous writer, whose reputation has extended to our own time. He attributed to the nervous system most of the functions and influences which Stahl ascribed to the *anima*. In speaking of the animal fibre, he ascribes to it a certain natural "tone," which may be increased into "spasm" or diminished to "atony;" and connected with both these hypotheses, while admitting the fluids to be sometimes primarily diseased, in the majority of cases he thought the solids were first affected.—As early as 1752 Boissier de Sauvages of Montpellier published his methodic nosology, in which he endeavors to class and distinguish diseases in the same manner as the vegetable kingdom is classed and described by the botanists. His work was of great use in the advancement of medicine, and remained the standard treatise on the subject until the publication in 1772 of the nosology of Cullen. This author, a professor first in the university of Glasgow and afterward in that of Edinburgh, contributed greatly to raise the latter school to the high rank which it has since enjoyed. His teaching and writings exercised a wide influence, and their effects can still be traced in English medicine in our own day; his descriptions of disease in particular are remarkable for their force and conciseness, but the progress of science has shown the fallacy of the views on which his system was founded. A contemporary and rival of Cullen, John Brown, a man of genius but of wayward and ill regulated character, was likewise the author of a sys-

tem which enjoyed a temporary popularity, and which, somewhat modified, found eminent followers in Italy within a recent period.—The end of the last century witnessed the most important practical discovery ever made in medicine. Up to that period small pox annually committed the most fearful ravages; the deaths from it in Europe alone were estimated to amount to 400,000 a year, while it left many others blind or disfigured. The practice of inoculation, brought from Constantinople by Lady Mary Wortley Montagu, had indeed diminished the evil, but the remedy itself was attended with great inconvenience, and was not destitute of danger. The discovery of Jenner, announced in his "Inquiry into the Causes and Effects of the Variolæ Vaccinæ" (London, 1798), has placed the disease completely under our control; and if it still commits occasional ravages, it is owing to the laxity of the laws and the carelessness of individuals. Another great improvement in practical medicine, the use of lemon juice, sour kraut, &c., in the dietary of seamen, by which scurvy, which formerly committed fearful havoc on both the naval and mercantile marine, has become almost unknown, is due to the naval surgeons of the last century.—In the last 60 years practical medicine has made greater advances than in any other similar period. This may be attributed: 1, to the brilliant discoveries which have rendered chemistry a new science, by the aid of which we are now able to comprehend much more clearly than before the processes of nutrition, respiration, calorification, secretion, and excretion; 2, to the increased attention paid to microscopy, by which the mode of development of the germ, the organization and growth of the different tissues, the process of repair and that of inflammation, and other morbid processes, have been investigated; 3, to the rapid progress of experimental physiology, aided by chemistry and microscopy; 4, to the increased cultivation of comparative anatomy and physiology; 5, to the cultivation of morbid anatomy not only in relation to the symptoms of disease during life, but to the various degrees of morbid developments, and to the relation which those developments bear to each other; 6, to the new and more perfect methods of investigating disease, by which its diagnosis has become more certain. Under the last head two discoveries are prominent, which have changed the whole face of medicine, giving it a degree of certainty which at one time seemed hopeless—that by Laennec of auscultation and percussion, and that by Bright of the disease of the kidney which bears his name. The development and perfecting of each of these discoveries has employed and is employing the lives and founding the reputation of a crowd of learned, zealous, and able men. 7. The discovery by pharmaceutical chemists of the active principles of various drugs, has not only rendered those drugs more certain and less nauseous, but has enabled us to exhibit necessary doses which the stomach otherwise would be unable to retain. 8. Not

only has the *materia medica* been benefited in the manner above mentioned, but by the discovery of various other remedies, by which diseases hitherto rebellious have been rendered more amenable to the resources of art; and by that of anæsthetics, one of the greatest boons medicine has ever conferred upon suffering humanity. (See HOMŒOPATHY, HYDROPATHY, and SURGERY.)

MEDINA. I. A S. W. co. of Texas, drained by the Medina river and Hondo and Seco creeks; area, about 1,100 sq. m.; pop. in 1850, 909, of whom 28 were slaves; present white pop. estimated at 1,500. The surface is rolling and in some parts hilly, and the soil fertile. In 1859 there were 18,200 head of cattle, and in 1857 10,000 acres under cultivation in Indian corn. Aggregate taxable property in 1859, \$447,255. Capital, Castroville. II. A N. co. of Ohio, drained by Black and Rocky rivers; area, 425 sq. m.; pop. in 1850, 24,441. The surface is uneven and the soil fertile. The productions in 1850 were 182,446 bushels of wheat, 418,027 of Indian corn, 215,380 of oats, and 806,602 lbs. of wool. There were 6 grist mills, 18 saw mills, 4 iron foundries, 8 tanneries, 42 churches, and 9,915 pupils attending schools. Capital, Medina.

MEDINA (Arab. *Medinet el Nabi*, "city of the prophet"), a city of Arabia, in the province of El Hejaz, situated upon the vast plateau of high land which forms central Arabia, about 250 N. from Mecca, in lat. 25° 15' N., long. 89° 30' E.; pop. about 18,000. It is the second in sanctity of the three holy cities of the Mohammedans. The sacred area is embraced within an imaginary line forming an irregular circle, of which the town is the centre, and of which the diameter is about 12 m. The place consists of 3 parts, a town, a fort, and a large suburb. The town itself is a walled enclosure, forming an irregular oval with 4 gates. The walls are well built of granite and lava blocks in regular layers, cemented with lime. The streets are narrow and dark, and only paved in a few places. There are few public buildings. The houses are well built of brick, basalt, and palm wood; the best of them enclose spacious courtyards and small gardens with wells. The castle joins on to the N. W. angle of the city, whose wall its own wall resembles, but its towers are more solid. The suburbs lie to the S. and W. of the town, and between it and them is the plain of El Munakhah, about 1,200 yards in length by 800 in breadth. In the suburbs the only buildings of importance are the governor's house, a plain building, and 5 mosques of stone, surmounted by cupolas and minarets. The mosque of the prophet, which is at the eastern extremity of the city, is the principal edifice, and is one of the most famous temples of the East. It is held in peculiar veneration by the Mohammedans, and a saying of Mohammed is cited to the effect that one prayer in this mosque is more efficacious than 1,000 in other places, save only the mosque at Mecca. The approach to the building is

choked up by common structures, some actually touching it, others separated by narrow lanes. There is consequently no general view to be had, and the building has a mean and tawdry appearance. It is a parallelogram about 420 feet long by 840 broad. It has a spacious central area open to the sky, surrounded by a peristyle with numerous rows of pillars, surmounted by small domes. There are 5 gates and 5 minarets. In the centre of the court is a piece of ground about 80 feet square enclosed by a wooden railing, and called the garden of Fatima, the prophet's daughter. Near this enclosure is the well of the prophet. In the covered part of the mosque are the tombs of Mohammed and of the caliphs Abubekr and Omar. They are concealed by a curtain of silk, and nothing is known with certainty about them, as they have never been seen by a Christian, and the accounts given by Mohammedan writers are very contradictory. At present even Mohammedans are not allowed to see them, the officers in charge declaring that whoever should look upon them would be blinded by supernatural light. This mosque has been many times destroyed and rebuilt, the last time in 1710. There is little commerce at Medina, and what trade exists is in grain, cloth, and provisions. The climate, though hot in summer, is severely cold in winter, owing to the elevation above the sea. The people are proud and indolent, and live in great part upon the revenues of the mosque, which has estates in almost all parts of the Mohammedan world.—Medina is of unknown antiquity. It is mentioned by Ptolemy under the name of Jathrippa, and is celebrated in Mohammedan history as the place to which the prophet fled from persecution at Mecca, and at which he died. From 682 to 678 it was the seat of the caliphate. Its subsequent history is of little importance.

MEDITERRANEAN SEA, a large inland ocean, almost landlocked, which divides Africa from Europe and touches Asia on its eastern extremity. Extending from lat. 30° to 46° N., and from long. 6° to 36° E., it has a length of 2,800 m., and a breadth varying from 1,200 to 80 m. (between Cape Bon in Africa and Sicily). Its area, including all its lesser basins and inlets, is over 1,000,000 sq. m. Its only point of connection with the Atlantic ocean is the strait of Gibraltar, through which a strong current toward the E. is perceptible, owing to the fact that the Mediterranean does not receive a sufficient afflux from rivers to make up for the loss of water caused by evaporation. A like current enters the Mediterranean proper through the straits of the Dardanelles from the Black sea, which is better supplied by large rivers. The current from the W. flows along the N. coast of Africa to Syria, where it turns to the N., and, being united with the current from the Black sea, flows along the European shore. In the Adriatic sea it flows up on the Dalmatian and down on the Italian coast, forming in the straits between Italy and Sicily the whirlpools which appeared so dread-

ful to the unskilful navigators of ancient times. The depth of the Mediterranean sea averages 8,000 feet, and is even 5,000 feet in many places, while in others the bottom is only from 40 to 180 feet below the surface. Such is especially the case between Sicily and Africa, and this is the principal basis of a theory according to which Europe and Africa were in an early period united at two points, Gibraltar and Sicily. The waters of the Mediterranean are subject to tides, which, however, are inconsiderable in comparison with other seas, and very irregular. The water is more salt than that of the Atlantic ocean, the proportion of saline ingredients which they respectively contain being as 41 to 88. The prevailing color is a deep blue, which changes into a greenish hue in the Adriatic, and further E. approaches purple. Beside a number of small streams, there are only 5 rivers of any importance emptying into the Mediterranean: the Ebro, Rhone, Po, and Adige on the N. shore, and the Nile in Egypt. The prevailing winds are mostly from the N. and W. Some of them are known by specific names, such as the mistral, a cold wind blowing from the Alps along the valley of the Rhone to the sea; its opposite, the sirocco, a scorching hot wind carrying the dry heat of the African deserts over the N. coast of Sicily and all Italy; and the bora (Boreas of the ancients), a N. wind usually accompanied by terrible thunderstorms. These winds, with waterspouts, which are very frequent, especially in the W. basin, render the navigation of the Mediterranean rather dangerous during certain seasons of the year. One of the peculiarities of the Mediterranean is the frequent occurrence of remarkable electrical phenomena, known as the St. Elmes fire, being balls of fire playing in mid air around the masts of ships, and called by the ancients Castor and Pollux. The scenery of the coast is as variegated as its lineal configurations. The entrance of the sea is marked by the steep and lofty rocks of Gibraltar and Genta (the pillars of Hercules), and the same character appears in the headlands by which the Pyrénées terminate at the sea, the Apennines on the gulf of Genoa, the Acroceraunian mountains on the Dalmatian and Albanian coast, and Mta. Pelion, Ossa, and Olympus on the coast of Thessaly; while at a great many other places the shore is low and even marshy. This is the case on a great part of the coast line of Italy. The African shore, with the exception of its westernmost part, is almost wholly devoid of considerable headlands. The shores of Naples and of Greece are especially celebrated for the beauty of their scenery. Of the many islands which dot the Mediterranean, Sicily, Sardinia, Candia or Crete, Cyprus, Negropont (the ancient Euboea), and Corsica are the most extensive. Beside these, the Balearic islands (Majorca, Minorca, and Ivica), Malta, the Ionian islands, and the islands of the archipelago deserve to be mentioned.—The Mediterranean was known to the ancient Romans as the *mare internum*,

though the specific designations of its different portions (Adriatic sea, *Ægean* sea, Tyrrhenian sea, Propontis or sea of Marmora, gulf of Genoa, gulf of Valencia, &c.) were more common. The shores of the Mediterranean have for thousands of years been the principal seats of civilization. The most important periods of the history of mankind have been determined by the rule of different nations over the countries bordering on this vast inland ocean. The Egyptians, the Phœnicians, the Hebrews, the Greeks, Romans, Carthaginians, and Saracens flourished there under distinct forms of society. The Mediterranean was always considered as the focus and the point of gravitation of political power, and even now every commanding position there is anxiously coveted by the nations that are able to aspire to political preponderance in Europe.

MEDUSA. See GORGONS.

MEDWAY (anc. *Vaga*), a river of England, which rises in the S. E. part of Surrey, and, after traversing Kent in a N. N. E. direction, falls into the estuary of the Thames at Sheerness near its mouth. It is about 60 m. long, and navigable to Penshurst, a distance of 40 m. In its lower course it expands into a broad, deep tidal inlet, and a little above its embouchure it sends off a navigable branch on the right called the East Swale, which cuts off from the mainland the isle of Sheppey. The Medway is one of the most important havens for the British fleet, and on its banks are two large government dockyards, Sheerness and Chatham. Ships of the line can anchor in the channel as far up as Maidstone.

MEEK, ALEXANDER BEAUFORT, an American author and lawyer, born in Columbia, S. O., July 17, 1814. His father, a physician and clergyman of the Methodist church, removed with his family to Alabama in 1819, and settled at Tuscaloosa. The son was graduated at the university of Alabama, and in 1835 was admitted to the bar, and in the same year became editor of the "Flag of the Union," a democratic journal published at Tuscaloosa. In 1836 he went to Florida as lieutenant of volunteers against the Seminole Indians. The campaign lasted 8 months, at the close of which Mr. Meek returned home and was appointed attorney-general of the state; but he soon resigned this office for the purpose of engaging regularly in the practice of his profession. In 1839 he edited "The Southron," a literary monthly at Tuscaloosa. In 1842 he was appointed judge of the county court of Tuscaloosa co., and held this office for nearly two years, during which time he prepared and published a supplement to the "Digest of Alabama." In 1845 he was appointed law clerk in the office of the solicitor of the treasury at Washington, and in 1846 removed to Mobile, having received the appointment of U. S. district attorney for the southern district of Alabama, an office which he held for 4 years. In 1848 he became associate editor

of the "Mobile Daily Register," which position he held for 5 years, though at intervals during that period his editorial labors were interrupted by other duties. In 1853 he was elected to the legislature, where he distinguished himself by originating and securing the establishment of a free school system in Alabama. In 1854 he was appointed judge of the probate court of Mobile co. to fill a vacancy, and at the election in the following year was an unsuccessful candidate for the same office. In 1855 he published "The Red Eagle, a Poem of the South," a romance founded upon the career of Weatherford, the famous chief of the Creek Indians. In 1856 he served as presidential elector on the democratic ticket. In 1857 he published a volume of orations, sketches, and essays entitled "Romantic Passages in South-Western History," and "Songs and Poems of the South," being a collection of his miscellaneous productions for several years. In 1859 he was again elected to the legislature, and upon the meeting of that body he was chosen speaker of the house. Beside the works enumerated, he has delivered before different societies a great many orations, essays, and criticisms, in prose and verse, and has now (1860) nearly ready for the press a history of Alabama.

MEERSCHAUM (Germ., sea foam, so called from its lightness and whitish appearance), or **MAGNESITE**, a hydrous silicate of magnesia, of composition represented by the formula $MgO, SiO_2 + 2HO$. It is a mineral of soft earthy texture somewhat resembling chalk, of hardness 2.5, and of variable specific gravity. It is found in Spain and several countries at the head of the Mediterranean, occurring in the form of veins in serpentine, and also in tertiary deposits. Dr. J. Lawrence Smith found it in Asia Minor in alluvium, apparently the result of the decomposition of carbonate of magnesia belonging to neighboring serpentine rocks. It is largely collected there for the manufacture of pipes and cigar tubes, the town of Kouieh furnishing the principal supplies. It is roughly shaped into blocks, or sometimes into rude forms of pipes, for exportation, and freed as far as practicable from the associated minerals which impair its quality by interfering with the carving and smoothing of its surface. It is fashioned into finished pipes, which are often highly ornamented, in different cities of Europe. Pesth and Vienna were formerly famous for this manufacture. To produce the yellow and brown colors, which are much admired in the pipes, and which are brought out only after long smoking, the blocks are kept for some time in a mixture of wax and fatty matters. A portion of these is absorbed, and, being subsequently acted upon by the heat and the tobacco fumes, assumes various shades of color. The lightest qualities are too porous for producing the best pipes; and the heaviest are rejected from suspicion of their being artificial products. These artificial preparations are from the parings of the genuine material, which, being reduced to fine powder

are boiled in water and moulded into blocks, sometimes with the addition of clay. After drying and contracting, they are ready for carving. This kind is known by the name of *mama-köpfa* or *massa* bowls. In the jury report of the London exhibition of 1851, it was stated that there was no certain test for distinguishing the real meerschaum from the preparations. The latter are generally heavier, and are more free from blemishes, some of which, arising from the presence of foreign minerals, are often seen in the genuine meerschaums. The value of the pipes and cigar tubes imported into the United States in 1858, it is stated, amounted to \$200,000.

MEERUT, a British district of Hindostan, in the lieutenant-governorship of the North-West Provinces, forming part of the Doab, and bounded E. by the Ganges and W. by the Jumna; area, 2,882 sq. m.; pop. in 1851, 1,135,072, of whom 885,288 were Hindoos. A ridge of low hills traverses the district from N. to S., separating the valleys of the Ganges and Jumna, but the general character of the surface is remarkably level. The soil is abundantly watered by the two great rivers above mentioned, and by the Ganges canal, about 50 m. of which lies in the district of Meerut. The vegetation of the tropics alternates here with that of more northern latitudes, wheat being cultivated in the cool season, and sugar cane, indigo, and cotton in the wet. The climate is one of the finest in India.—**MEERUT**, the capital of the above district, is situated on the river Kalee Nudda, nearly equidistant from the Ganges and the Jumna, 980 m. N. W. from Calcutta, and 33 m. N. W. from Delhi; pop. 29,014. The streets are narrow and dirty, and the native part of the town is wretchedly built, though it contains some ruined mosques and pagodas of considerable architectural interest. It is an important military station, having an extensive cantonment about 2 m. distant. The English church, which is capable of holding 3,000 people, is one of the finest in India.—Meerut is noted as the scene of the outbreak of the sepoy rebellion in 1857. It contained at that time about 4,300 troops, nearly half of whom were Europeans. The native soldiers showed insubordination as early as the month of April; and on May 9. 50 troopers were imprisoned for refusing to receive the new cartridges. On the next day, Sunday, the comrades of these men and the sepoys of the 20th native infantry rushed from their lines on a given signal and proceeded to the quarters of the 11th native infantry, whose colors fell riddled with balls while endeavoring to persuade them to return to their duty. The 11th now joined the rebels, the imprisoned troopers were released, 1,200 ruffians were let loose from the gaol, and the mutineers and the rabble began to set fire to the cantonment and to murder every European who fell in their way. In the mean time the English troops, who previously commanded would have been a match for 4 or 5 times their number of natives, were manoeuvred with such inefficiency that the reb-

els had their own way for several hours, and then took the road to Delhi, scarcely any attempt being made to pursue them. The British commander, Gen. Hewitt, was much censured for his conduct at the time, but in the judgment of many his course was after all the wisest that could have been taken under the circumstances.

MEGALONYX (Gr. *μεγας*, *μεγαλη*, great, and *ονξ*, claw), an extinct genus of giant edentates, allied to the sloths, established in 1797 by Thomas Jefferson, in a communication to the American philosophical society of Philadelphia, in whose "Transactions" the bones were described by Dr. Caspar Wistar, who first suggested the affinity of the animal to the recent sloths. The first bones were discovered in a limestone cavern in western Virginia, and were referred by Mr. Jefferson, from the large size of the claws, to some carnivorous animal; the original specimens of this, the *M. Jeffersonii* (Harlan), are in the cabinet of the academy of natural sciences at Philadelphia. These, and other bones found in Tennessee, Kentucky, Mississippi, and Alabama, form the materials of the most complete monograph on the subject, that of Prof. Joseph Leidy, in vol. vii. of the "Smithsonian Contributions to Knowledge" (1855). The skull is about 14 inches long, with the upper outline nearly horizontal, depressed forehead, and convex nose; the sagittal crest prominent and rugged; zygomatic process strong, and temporal fossa rough for the attachment of muscular fibres; the mastoid process strongly marked; the orbital cavity shallow; the hard palate between the 3 posterior molars 14 lines wide, with a median convexity nearly as prominent as the teeth, becoming almost plane in advance of the 3d molars, and varying in width from 2½ to 4 inches, perforated by large foramina and by a large incisive foramen between the 1st molars; the occipital foramen circular, 16 lines in diameter, the surface of this bone being rough for the attachment of powerful muscles; orifice of nose irregularly circular, about 3 inches in diameter; lower jaw about 13 inches long. The teeth are long, without fangs, sub-elliptical, of nearly uniform diameter, with the crown hollowed in the middle and projecting border; as in other edentates, they are deeply excavated from the bottom for the persistent dental pulp; they have no enamel, being composed of very porous dentine in the centre, surrounded by a harder layer of the same which is enclosed by a thinner crust of cementum; the formula is $\frac{f-1}{f}$, the anterior tooth being considerably in advance of the others, in form and position like a canine; they vary in diameter from 8 lines to an inch; the rami of the lower jaw are widely separated, and the symphysis narrow. The bones of the skeleton are strong, though less so than in the allied megatherium; the scapula is about 1½ feet long, the humerus 20 inches; the thigh bones relatively shorter and broader than in the sloths and about 21 inches long. the tibiae

relatively very much shorter than in the sloths, but of greater relative length than in the mylodon; the shaft of the humerus suddenly expands toward the lower extremity, and is pierced by a large foramen; the astragalus like that of recent sloths, 5½ by 3½ inches; the heel bone developed in an extraordinary manner, being long, compressed, and high; the phalanges large and narrow, and armed with powerful claws; the tibia and fibula distinct, and the foot articulated obliquely, the last leading Mr. Lund to the opinion that the animal was a climber; the anterior limbs a little larger than the posterior; the tail strong and solid. From the study of the toes Cuvier pronounced the animal an edentate; the well-marked ridge in the middle of the articulating surface of the last phalanx indicates a more restricted motion than in carnivora, to which Mr. Jefferson referred it; the upper edge extends further back than the lower, preventing the claws from being raised above a horizontal line, but permitting complete flexion below, as in sloths; their form and proportions are also those of edentates; the middle and ring fingers are large, with very strong claws, the index being smaller with a less strong claw, and the thumb and little finger rudimentary. This animal was less heavy in form than the megatherium, which it doubtless resembled in its habits; it was probably of the size of a large ox. The bones are found in the pleistocene or drift formations of America, contemporaneous with the elephant and mastodon, and perhaps surviving them; bones of another species are found in Brazil. Like the megatherium, it probably used its powerful claws, not to dig subterranean retreats, nor to climb, nor to uncover edible roots, but to loosen trees, and break them down by its weight, in order to feed upon their leaves. (See **MEGATHERIUM**.)

MEGALOPOLIS, a city of ancient Greece, in the territory of Arcadia, on the river Helisson. It was founded at the suggestion of Epaminondas, after the battle of Leuctra, in 371 B. C., and was designed by him as a counterpoise to the power of Sparta. Forty townships furnished inhabitants for the new city, which was 50 stadia in circumference, and had a larger domain allotted to it than that possessed by any other Arcadian state. Megalopolis, from the period of its foundation, became the capital of the Arcadian confederacy, and the seat of the general assembly. Apprehension of Sparta afterward drove the Megalopolitans into alliance with the Macedonians, and held them aloof from the coalition formed in Greece on the death of Alexander for the recovery of independence. They at length fell under the dominion of tyrants, the last of whom, Lydiades, resigned his authority in 234 B. C., and united Megalopolis to the Achaean league. In 222 Cleomenes III., king of Sparta, captured it by surprise, and destroyed the greater part of it; but after his defeat at the battle of Sellasia, the Megalopolitans who had previously fled returned under the conduct of Philopœmen,

and rebuilt their city, which however never regained its former prosperity, and on the death of Philopœmen rapidly sunk into insignificance. Polybius the historian was a native of this city. The ruins of its theatre, once the largest in Greece, are still to be seen at the village of Sinano.

MEGALOSAURUS (Gr. *μεγας*, great, and *σαυρα*, lizard), a gigantic fossil reptile of the family of dinosaurians, which includes the iguanodon, previously described. This family, entirely extinct, was remarkable for great size and for certain mammalian characters; the long bones have a medullary cavity, the feet are short and pachyderm-like, the sacrum composed of at least 5 anchylosed vertebræ, the ribs doubly articulated to the spine, the vertebral laminae greatly developed, and the lower jaw capable of a horizontal triturating motion; but the teeth, scapular arch, and most of the skeleton resemble those of lizards. The genus *megalosaurus* (Buckland) was discovered by Dr. Buckland in the Stonesfield oolite near Oxford, Eng.; their remains have also been found in the wealden and jurassic formations. The *M. Bucklandi* (Cuv.), the best known species, had probably a straight muzzle, thin, and laterally compressed; the teeth were flat, pointed, curved backward like a pruning knife, with the enamel of the posterior edge serrated to the base, and for a short distance from the point also on the anterior; the structure of these teeth, calculated to lacerate flesh and to hold a prey once seized, shows that the animal was highly carnivorous. The teeth, some of them 8 inches long, were implanted in distinct sockets formed by partitions running across from the higher external to the lower internal border of the jaw, combining crocodilian and lizard characters. This animal must have attained a length of 30 or 40 feet; it was terrestrial, and probably preyed upon the smaller reptiles and the young of the larger.—The dinosaurian genus *hylæosaurus* (Mantell), or wealden lizard, was discovered by Mantell in the wealden of Tilgate forest in 1832; it shows a similar blending of crocodilian and lizard characters. The bodies of the vertebræ are biconcave, rather short, with well-developed laminae and large processes; the transverse processes indicate the support of large dermal plates, and perhaps of a dorsal crest as in iguanas; the scapula is crocodilian, and the coracoid lacertian; the teeth were probably like those of the pleurodont lizards; the locomotive organs are imperfectly known; its length has been estimated at from 25 to 30 feet. The *H. armatus* (Mantell) was terrestrial and carnivorous.

MEGARA, a city of ancient Greece, capital of Megaris, situated about 1 m. from the sea, opposite the island of Salamis, 26 m. N. W. from Athens, and 81 m. N. E. from Corinth, in lat. 38° N., long. 23° 21' E. It consisted of a double acropolis and the city proper. The more ancient acropolis is said to have been built by Car, son of Phoroneus; the other, together with the city, by Alcathous, son of Pelops. Subsequently, however, a Dorian colony, under Alethes and

Athemeneas, took possession of the city, and enlarged it. Its original name appears to have been Polichne. In the 7th and 8th centuries B. C. Megara was opulent and powerful, and sent forth several colonies by whom the cities of Megara Hyblæa in Sicily, Astacusan Bithynia, and Chalcedon and Byzantium on the Bosphorus were founded. It even entered into a contest with Athens, in the time of Solon, for the island of Salamis, but was at length constrained to yield. In the Persian war it contributed 8,000 hoplites and 20 ships to the confederate forces. After the conclusion of that struggle Megara deserted the Peloponnesian confederacy, and joined that of Athens, to which ere long it became virtually subject; and the Athenians, to secure their supremacy over it, built the long walls which connected Megara with its port Nisæa. The Athenian garrison, however, was expelled by the aid of some Peloponnesian troops in 445 B. C. This so exasperated the Athenians that they passed a decree excluding the Megarians from their markets and harbors, which decree operated so injuriously to the interests of the latter that its enforcement was one of the pretexts advanced by the Spartans and their allies for the commencement of the Peloponnesian war. During that war Megara suffered severely from siege and famine, the Athenians being still in possession of Nisæa; and subsequently, though it recovered a considerable portion of its ancient prosperity, it does not figure prominently in history. It was celebrated for its philosophical school, founded by Euclides, the disciple of Socrates. Comedy is said to have been invented in Megara, and introduced thence into Athens. Theognis, the elegiac poet, was born there.

MEGARIS, a district of ancient Greece, bounded N. by Boeotia, E. by Attica, S. by the Saronic gulf, and W. by Corinth and the Corinthian gulf; area about 148 sq. m.; capital, Megara. It is in general a rugged and hilly country. The principal mountains are Mt. Cithæron, which separates it from Boeotia, and the Geranean chain, which extends E. and W. across its S. part from sea to sea. Through this chain are three passes: one, styled the Scironian pass, runs by the Saronic gulf, and formed the direct road from Corinth to Athens; another, which runs along the Corinthian gulf, was the great thoroughfare between Boeotia and Peloponnesus; and a third crosses the centre of the mountains. The territory of Megaris contains no plain except that in which its metropolis stood. Its aboriginal inhabitants were Æolians and Ionians, and it originally constituted part of Attica.

MEGATHERIUM (Gr. *μεγας*, great, and *θηριον*, animal), an extinct edentate animal, of gigantic size, coming in many respects near to the sloth family, and with its allies, the megalonix and mylodon, seeming to form the transition from the edentates to the pachyderms. Pictet calls the family *gravigrada*, placing them between the sloths and the armadillos; in all the molars are hollow cylinders of dentine

and cement without enamel, the tube of dentine being filled with a porous substance; the form of the head, which is short and truncated, the large descending zygomatic process, and many parts of the skeleton (as the union of the acromion and coracoid processes of the scapula), resemble those of the sloths; the teeth consist only of molars, the canines of the sloths being absent; in their heavy forms, nearly equal limbs, and long and strong tail, they come nearer the armadillos and ant-eaters. The genus *megatherium* (Cuv.) is the first described of the family, the first skeleton having been sent in 1789 from the vicinity of Buenos Ayres to Madrid, where it now remains; since then other skeletons and fragments have been discovered in Peru, Paraguay, and other parts of South America; another species is described by Dr. Leidy in North America. This genus is distinguished from the other megatherioids by the quadrangular prismatic form of the teeth and the marked transverse ridge on the crown; the dental formula is $\frac{4}{1}-\frac{4}{1}$; the anterior limbs have 4 fingers, the posterior only 3, the 2 outer being without nails, the others with large claws. The well known South American species, *M. Cuvieri* (Desm.), is intermediate in size between the elephant and the rhinoceros; the skull is relatively longer than in sloths, and the large foramina for the passage of nerves and vessels indicate that the animal had very thick lips; the teeth, from 7 to 9 inches long, are implanted deeply in firm alveoli, and the ridges of the upper fit into the depressions of the lower; the lower jaw is large and heavy; the vertebrae are 7 cervical, 16 dorsal, 8 lumbar, 5 sacral, and 15 caudal, of medium size in the anterior portions of the body; those of the tail are enormous, the largest measuring 18 inches from one end of the transverse process to the other; the V-shaped bones are also greatly developed, the tail serving as a means of support and perhaps of defence; the ribs are short and thick, and roughened for muscular attachments. The anterior limbs are remarkable for the strength of the shoulder, the clavicle being massive and curved like the letter S, and the acromion and coracoid processes united; the humerus is much enlarged at the lower portion to support a wide ulna and a radius freely turning around it, as in the monkeys and sloths; the large processes indicate immense force of rotation; the fore feet were strong, and armed with powerful claws. The pelvis is very large and solid, measuring 4½ feet from hip to hip, considerably more than the largest elephant; the cotyloid cavity is directed downward, so that the thigh bones support the body without obliquity, securing great strength and solidity at the expense of rapidity of motion; the thigh bones are at least 3 times as thick as in the largest elephants, and the length is only double the width; the tibia and fibula are very thick, and united at the top; the heel bone is almost as long as all the rest of the foot, and the nail of the middle toe enormous. These details suffice to show that the megatherium

was a very large and powerful animal; the entire fore foot being about a yard long and the claws set on obliquely to the ground, it may be inferred that the anterior limbs were principally used for the purpose of digging; the great size of the pelvis and hind legs, and strength of the tail, were necessary to sustain so heavy an animal in an upright position while using its fore feet in digging around the trees which it afterward prostrated by the weight of its body. The teeth show that it was herbivorous, feeding on the stems and roots of trees and succulent fruits. Their size and structure indicate that they did not burrow under ground like the mole, nor climb trees like the sloth, nor dig up roots or ant hills like the armadillos and ant eaters, but loosened and cut the roots of trees with their powerful claws, and then, supported on the hind limbs and tail, pulled them down with the fore limbs aided with the great weight of the body. Like the living sloths, this species was limited in geographical distribution to South America, in the alluvial deposits of which, on the immense plains called the Pampas, their bones have principally been found. Dr. Leidy, in vol. vii. of the "Smithsonian Contributions to Knowledge" (1855), describes a North American megatherium (*M. mirabile*, Leidy), discovered in the maritime portion of Georgia and upon the shores of Ashley river, South Carolina, in connection with bones of the elephant, mastodon, horse, and ox; it is now preserved in Washington and Philadelphia. (See MYLODON for comparative measurement and other interesting points.)

MEGISSEE Co., Mich. See ANTRIM.

MEHEMET ALI, or MOHAMMED ALI, pasha of Egypt, born at Kavala, a small seaport town of Macedonia, in 1769, died in Cairo, Aug. 8, 1849. He lost his father at an early age, and was brought up by the governor of the town. Soon after attaining the age of manhood he was made a collector of taxes, and by his energy and resolution in this office acquired such favor that he was made *buluk-bashi* or commander of a body of infantry, and received a rich relation of the governor in marriage. He next became a tobacco merchant, and had acquired considerable property when in 1799 he was sent to Egypt as second in command of the contingent of 800 men furnished by his native place to the Turkish army, despatched to that country to carry on the war against the French expedition commanded by Napoleon Bonaparte. Soon after his arrival he succeeded to the principal command of his corps, with the rank of *bin-bashi* or commander of 1,000 men. His ability attracted the notice of the pasha and of the soldiers, and he soon became one of the most distinguished and popular of the military chiefs of the Turkish army in Egypt. After the expulsion of the French a civil war broke out between the Turks and the Mamelukes, in which Mehemet Ali took an active part. In 1803 the Albanians in the ser-

vice of the pasha revolted because they could not get their pay, and after several conflicts in Cairo they became masters of the city, under the direction of Mehemet Ali. A long and confused struggle now ensued between various factions, the result of which was that in May, 1805, Mehemet Ali was invested with the supreme authority by the principal inhabitants of Cairo, as the only man capable of restoring order; and shortly afterward his elevation was confirmed and made legal by a firman from the sultan. But although he possessed the title of pasha of Egypt, his authority did not actually extend beyond the walls of Cairo, as everywhere in the country the Mameluke beys were still in rebellion. On Aug. 17, 1805, a considerable body of the beys, who with their followers had encamped not far from Cairo, were enticed into making an attempt to seize upon the city. They forced an entrance by a gate purposely left undefended, and marched triumphantly through the streets until they were suddenly surrounded by the troops of the pasha, who slaughtered them without mercy, a few only breaking through and escaping. The rest of the Mamelukes fled to Upper Egypt, whither Mehemet Ali pursued them with a considerable force. He had defeated them near Asiout when the arrival of a British expedition at Alexandria, March 17, 1807, consisting of 5,000 men under Gen. Fraser, who had been sent to conquer Egypt and restore the beys to power, led him to conclude a truce with the beys, and to promise to comply with all their demands if they would cooperate against the invaders. Most of them agreed to his proposals, and were marching against the British, when Gen. Fraser, who had been already several times defeated by the pasha's troops and had lost about 1,000 men, re-embarked his army and abandoned the country, Sept. 14. Many of the beys now took up their abode in Cairo, and for 3 or 4 years Egypt was comparatively tranquil, notwithstanding occasional battles between the Mamelukes and the pasha's troops, in one of which the latter were signally beaten. At length, on March 1, 1811, Mehemet Ali enticed all the Mamelukes in Cairo into the citadel on pretence of witnessing the ceremony of investing his son Toosoon with the command of an army to be sent against the Wahabees in Arabia. The gates of the fortress were then closed upon them, and they were killed to the number of 470. Immediately afterward the pasha's officers and soldiers throughout Egypt massacred all the Mamelukes within their reach. The few who escaped fled to Nubia, where they dwindled away till the corps became extinct. These energetic proceedings, atrocious in the eyes of Christendom, but not abhorrent to the theory and practice of oriental governments, fully established the power of Mehemet Ali, and gave to Egypt an internal tranquillity unknown for ages, and which has lasted to the present time. Toosoon Pasha was now sent with 8,000 men against the Wahabees, from whom he recaptured the sacred cities

of Mecca and Medina, and whose leader he took prisoner. He subsequently met with disasters, however, and in 1813 Mehemet Ali himself went to Arabia to conduct the war. He was successful, and in 1815 returned to Egypt after concluding a treaty with the Wahabee chiefs. He now made an attempt to introduce the European system of discipline into his army; but a formidable mutiny breaking out in consequence among the soldiers, he temporarily abandoned his design. The Wahabees not having fulfilled all the conditions of the late treaty, he sent his son Ibrahim against them in 1816, with an army composed in part of the recent mutineers. The expedition succeeded in capturing El Derayah, the Wahabite capital, and in suppressing all armed opposition in Arabia to the sultan's power. Mehemet Ali now turned his attention to the improvement of manufactures in Egypt, and to the revival of the commerce of the country. He also caused the construction, at an enormous sacrifice of the laborers from sickness and want, of a great canal from Alexandria to the Nile. In 1820 his youngest son Ismael was sent with an army to conquer Sennaar, and to collect captives to be sent to Cairo with the view of forming them into an army disciplined in the European manner. Nubia, Sennaar, Dongola, and Kordofan were subdued; and although in 1822 Ismael was surprised and with his retinue burned to death by a native chieftain, these provinces have since remained subject to Egypt. The captives taken in Sennaar and Kordofan were trained by French officers, as were also many thousands of the native Fellahs of Egypt, who it was found made very good troops. In 1828 the army thus organized amounted to 24,000 men. In 1829 the pasha sent about 8,000 Albanians to assist the Turks in suppressing the Greek insurrection. He also sent his fleet, which was engaged at Navarino, and chiefly supported the contest till in 1828 the European powers compelled him to withdraw his troops from the Morea. In 1831 Mehemet Ali sent an army of 38,000 men into Syria under command of Ibrahim Pasha, ostensibly to chastise the pasha of Acre for refusing to deliver up a multitude of deserters who had taken refuge in his territories, but in reality for purposes of conquest and aggrandizement. This step brought him in immediate conflict with his suzerain the sultan, to whom he still professed allegiance. Ibrahim took Acre after a long siege, and rapidly overran Syria, defeating the Turks in a great battle at Homs, July 8, 1832. He then advanced into Asia Minor, and at Konieh on the plains of Anatolia encountered the grand vizier Reshid Pasha with 60,000 men, his own army being less than 30,000. The discipline of the Egyptians prevailed, the Turks were routed, Reshid was made prisoner, and Ibrahim was within 6 days' march of Constantinople, when the European powers intervened and compelled Mehemet Ali, in May 1833, to accept a treaty by which the whole of Syria and the district of Adana in Asia Minor were ceded

to him, beside the island of Candia, which he had formerly received for his services in Greece. The sultan was not disposed to submit quietly to the losses inflicted by his rebellious vassal; and in June, 1889, after long and vast preparation, the Turkish fleet sailed for Egypt, and an army of 80,000 men commanded by Hafiz Pasha invaded Syria. It was met by Ibrahim with 46,000 men at Nisib, June 24, and utterly routed in less than two hours. Hardly had the news of this triumph reached Alexandria when the Egyptian fleet entered the port of Alexandria, bringing with it the whole Turkish fleet, which had, through treachery, surrendered without a battle. The Turkish empire was now again preserved from total destruction by the intervention of Great Britain, Russia, Austria, and Prussia, although France, under the short ministry of Thiers, strongly favored Mehemet Ali. Alexandria was blockaded, and a British fleet bombarded and captured Beyrout and Acre. Terrified by these vigorous demonstrations, Mehemet Ali accepted terms of peace dictated by the allies, by which the pashalic of Egypt was secured to him and his descendants, on condition of paying one quarter of his clear revenues to the sultan as tribute, restoring to him his fleet and the Syrian provinces, and limiting his own army to 18,000 men. Henceforth Mehemet Ali devoted himself to the internal improvement of Egypt. The administration of the government was reformed on European models and under European advice. New systems of taxation, of import and export duties, of quarantine, and of police were introduced. Colleges for the study of languages and of medicine were established, and also printing presses, together with many minor improvements. With few exceptions all former usages were destroyed, and an entirely new system of government formed. Cotton was introduced and largely cultivated, and many extensive manufactures were created. Among the public works of utility, one of the most important was the barrage of the Nile, a vast undertaking scarcely yet complete. In 1847 Mehemet Ali for the first time visited Constantinople, where he was well received, and had the rank of vizier conferred upon him. In 1848 he became imbecile from extreme old age, and his son Ibrahim was appointed pasha in his stead; but the latter died two months afterward while his father yet lived, and was succeeded by his nephew Abbas Pasha, son of Toosoon.—An English writer, long resident in Egypt and thoroughly acquainted with the country, Mr. R. S. Poole, says of Mehemet Ali: "That he really esteemed European civilization may be doubted; but his intelligent mind could not fail to perceive that therein lay his great strength, and of this he availed himself with consummate ability. To his firm government Egypt is indebted for the profound tranquillity which it has long been its good fortune to enjoy; a traveller of any name or faith may traverse it in its length and breadth with greater security than almost any other

country out of western Europe; and the display of fanaticism has been rigorously punished. This has undoubtedly increased the hatred of the Muslims for the professors of other religions; but we may hope that it will eventually produce a better state of feeling. While, however, Egypt has benefited by the establishment of order, the people have suffered most severe exactions. The confiscation of private lands has been before mentioned; to that arbitrary act must be added the seizure of the lands of the mosques, the imposition of heavy taxation, and a system of merciless impressment. In fact, the condition of the Egyptian Fellah has rarely been as wretched as it is at the present day. He also misunderstood the real resources of Egypt, which are certainly agricultural; by the much lauded introduction of cotton he dealt a severe blow to native produce; and he did more to injure the country by endeavoring to encourage manufacturing industry, and by establishing enormous government monopolies, a measure which crushed the spirit of the agriculturists. His military and governing abilities were assuredly very great, and his career is almost unequalled in Turkish history."

MÉHUL, ÉTIENNE HENRI, a French composer, born in Givet, Ardennes, June 24, 1768, died Oct. 18, 1817. He was of humble extraction, and having shown a strong taste for music was at the age of 16 taken to Paris, where he was instructed in dramatic composition by Gluck. He wrote 3 or 4 entire operas, but did not appear before the public as a composer until 1790, when his *Euphrosine et Coradin* was produced with great success. His *Stratonice*, which appeared 2 years afterward, established his reputation. Critics complained of a lack of graceful melodies in his operas, and of a dryness and monotony in the harmony and accompaniments. He seems to have justified this censure by the startling innovations he attempted to introduce into operatic composition, as in the opera of *Uthal*, produced in 1806, in which he excluded the violins from the orchestra; but in his *Joseph*, in 1807, he vindicated his claim to be ranked among the great composers. This opera is regarded as his *chef d'œuvre*, and has frequently been performed in England as an oratorio. He composed in all 42 operas, beside ballet music, songs for the festivals of the republic, and a variety of instrumental pieces, including the *Ouverture du jeune Henri*, which is considered an admirable specimen of descriptive music. He was an inspector of the conservatory, and, after the suppression of that institution, professor of composition at the royal school of music and declamation.

MEIBOM, a learned German family, whose most eminent members were HEINRICH (born in 1638, died in 1700), who made important discoveries in anatomy, and MARKUS (1630–1718), whose most celebrated work is *Antiqua Musica Auctores Septem* (Amsterdam, 1652). The fame of the latter procured invitations for him at the courts of Sweden and Denmark, and he officiat-

ed as professor of belles-lettres in Upsal, Amsterdam, and other places. He also visited France and England, but was a person of unsteady habits, and died in penury.

MEIGS. I. A S. E. co. of Tenn., bounded N. W. by the Tennessee river; area, 215 sq. m.; pop. in 1850, 4,879, of whom 395 were slaves. The surface is hilly and the soil fertile. The productions in 1850 were 432,875 bushels of Indian corn, 72,022 of oats, 18,890 of sweet potatoes, and 17,667 lbs. of tobacco. There were 15 grist mills, 9 saw mills, 19 churches, and 2,145 pupils attending public schools. Capital, Decatur. II. A S. E. co. of Ohio, bordering on Virginia, and bounded E. by the Ohio river; area, 425 sq. m.; pop. in 1850, 17,971. It has a broken surface and clayey soil. There are mines of coal along the river, and large salt works. The productions in 1850 were 113,091 bushels of wheat, 267,404 of Indian corn, 70,550 of oats, and 44,142 lbs. of wool. There were 17 grist mills, 26 saw mills, 2 iron founderies, 7 tanneries, 37 churches, and 5,366 pupils attending public schools. Capital, Pomeroy.

MEIGS, JAMES ATKINS, an American physician and author, born in Philadelphia, July 31, 1829. He was graduated at Jefferson medical college in 1851; chosen librarian of the academy of natural sciences of Philadelphia in 1856; elected in 1857 to the chair of institutes of medicine in the Philadelphia college of medicine, and in 1859 transferred to the same chair in the medical department of Pennsylvania college, which post he now (1860) occupies. In 1857 he arranged and classified the collection of human crania in the academy of natural sciences, of which he published a catalogue. In the same year he edited Kirke's "Manual of Physiology," and contributed to Nott and Gliddon's "Indigenous Races of the Earth" an elaborate article on "The Cranial Characteristics of the Races of Men," which is a very complete general survey of human skulls in their ethnical relations. In 1858 he published "Hints to Craniographers on the Importance and Feasibility of some uniform System for the collection and promulgation of Craniological Statistics, &c.;" and in 1859 an erudite paper on a deformed, fragmentary skull, from a quarry cave in Jerusalem. Dr. Meigs has also been an active contributor to various scientific periodicals.

MEIGS, RETURN JONATHAN, an American revolutionary soldier and western pioneer, born in Middletown, Conn., in Dec. 1740, died at the Cherokee agency, Ga., Jan. 28, 1823. At the commencement of the revolutionary war he raised a company of men and marched to the American camp at Cambridge, subsequently accompanied Arnold on his expedition against Quebec, where he was taken prisoner, and after his release was commissioned a colonel in the continental army. He signalized himself by a brilliant expedition against a British post at Sag Harbor on Long island, for which he received the thanks of congress and a sword, and took a distinguished part in the capture of Stony Point

under Gen. Wayne, and elsewhere in the course of the war. In 1788 he emigrated to Ohio, and established himself at Marietta. In 1801 he was appointed by President Jefferson Indian agent of the Cherokees, among whom he passed the remainder of his life.

MEINERS, CHRISTOPH, a German historian, born in a village of Hanover in 1747, died in Göttingen, May 1, 1810. He was educated at the university of Göttingen, where in 1771 he was appointed professor of philosophy, and subsequently vice-rector. He was charged with the task of selecting professors of science and literature for the Russian colleges by the czar Alexander. Of his numerous works, the most important are devoted to the history of religion, philosophy, and science.

MEISSEN, a town of Germany, in the kingdom of Saxony and circle of Dresden, on the left bank of the Elbe, 15 m. N. W. from Dresden; pop. 8,914. It is celebrated for its manufactures of porcelain, known as Dresden china. It was founded in the earlier part of the 10th century by Henry I. of Germany, and during the middle ages figured as the seat of a margravate, bishopric, and burgraviate of its name, or Misnia.

MEISSONIER, JEAN LOUIS ERNEST, a French painter, born in Lyons in 1815. He established himself when a young man in Paris, studied painting under Coignet, and in 1836 exhibited his first pictures, "The Chess Players" and "The Little Messenger," which attracted considerable attention by their spirited expression and miniature-like delicacy of execution. He has since that period devoted himself almost wholly to small pictures of *genre*, the subjects of which are generally similar to those selected by the old Dutch and Flemish masters, whom he more nearly approaches than any of his countrymen, or perhaps than any other living painter, at the same time that he preserves sufficient originality of manner to avoid being classed among imitators. Several of his works have been exhibited in the United States; among the best are "The Reader;" "The Chess Players," which in 1841 gained him a 2d class medal of the academy of fine arts; "The Painter in his Studio," for which in 1848 he obtained a first class medal; "The Game of Piquet," "The Bowlers," "The Smoker," "Soldiers," &c. He has recently been commissioned to paint a picture of the emperor Napoleon at the battle of Solferino, and one of the emperors Napoleon and Francis Joseph at Villafranca, for which purpose he has made visits to Italy and Vienna. He has at various times painted small portraits and furnished vignette designs for illustrated books, including an edition of "Paul and Virginia." At the exhibition of 1855 he received one of the grand medals of honor, and in the following year he was created an officer of the legion of honor. His pictures bring immense prices, and his style has many imitators.

MEJERDA (anc. *Bagradas*), a river of N. Africa, formed by the union of several streams

which rise in the Atlas mountains in Algeria, and running N. and N. E. through the regency of Tunis to the gulf of Tunis, into which it falls, 24 m. N. of the city of that name. Its whole course is about 200 m., and it is the only considerable river of Tunis. As it approaches the sea it enters a wide plain whose numerous lakes or ponds seem to have been formed by inundations of the river. Its waters are deeply colored by the soil, and the mass of sediment which it bears down has enlarged its delta and made many alterations in the coast line. Its whole lower course has changed, the ruins of Utica now standing close to its left bank, whereas in ancient times it flowed much nearer to Carthage. Its original Punic name is thought to have been Macaras.

MEKONG RIVER. See CAMBODIA.

MELA, POMPONIUS, a Roman geographer, who most probably flourished in the reign of the emperor Claudius. He was a native of Spain, and is said to have been the first Roman author that composed a methodical treatise on geography. His work is entitled *De Situ Orbis*, and consists of 3 books, which give a brief description of the whole world as known to the Romans. The text is corrupt, but the style is simple, and the Latinity pure. The *editio princeps* appeared at Milan in 1471; the best edition is that of Tzschucke (Leipsic, 1807).

MELAMPUS, in Grecian mythology, son of Amythaon by Idomene, Aglaia, or Rhodope, esteemed the first mortal who had been endowed with the gift of prophecy, and who had practised the medical art. He is said to have been the introducer of the worship of Bacchus into Greece.

MELANCHOLIA. See INBANDITY.

MELANCHTHON, PHILIPP, the second leader of the Lutheran reformation, sometimes called the "teacher of Germany," born in Bretten, in the Lower Palatinate, now belonging to the grand duchy of Baden, Feb. 16, 1497, died in Wittenberg, April 19, 1560. His family name was Schwarzerd (black earth), but his uncle, the celebrated Greek scholar Reuchlin, translated it, after the literary fashion of the age of the revival of letters, into the corresponding Greek Melanchthon (sometimes written Melanthon, and incorrectly Melancthon). His parents were honest and pious, and in easy circumstances. He was educated at the Latin school of Pforzheim, and at the universities of Heidelberg and Tübingen. He distinguished himself by uncommon precocity of mind, and graduated as master of arts in 1514. He then began to lecture at Tübingen, and published a Greek grammar and editions of Aristotle and other classics. He took rank at once among the very first Greek and Latin scholars of the age. Before he had reached his 20th year (in 1516), Erasmus said of him: "My God! what expectations does Philipp Melanchthon excite, who is yet a youth, yea, we may say a mere boy, and has already attained to equal eminence in the Greek and Latin literature. What acumen in

demonstration, what purity and elegance of style, what comprehensive reading, what tenderness and refinement of his extraordinary genius!" With the study of Greek and Roman literature he combined a careful and reverent study of the Bible in the original. This, in connection with the influence of his friend and patron Reuchlin, predisposed him favorably to the great movement of the reformation, which commenced, during his residence at Tübingen, with the controversy between Luther and Tetzel in 1517. At the recommendation of Reuchlin he was called to the professorship of Greek at the rising university of Wittenberg in 1518, and thus became the colleague of Luther. Although he was subsequently called to other prominent positions in Nuremberg, Tübingen, Heidelberg, and even France and England, he preferred remaining at Wittenberg to the close of his life. He was decidedly the most popular teacher of the university, and attracted students from every direction. He had at times (as we learn from Heerbrand's *Oratio Funebris*) not fewer than 2,000 hearers, among whom were princes, counts, and barons, and heard 11 languages at his frugal table. Even Luther was not ashamed to sit at his feet. At first he lectured on classical literature, but in 1519 he was graduated as bachelor of divinity, and thenceforward devoted himself mainly though not exclusively to theology. Yet he did not properly belong to the clergy, having never been ordained; nor would he ever accept the title D.D. He never ascended the pulpit, although he frequently wrote sermons for others, and delivered in his house practical lectures on the Gospels in Latin, which were taken down by some hearers and published as sermons (*Postilla*). He was therefore a lay theologian; but as such he was of the greatest importance in that great ecclesiastical movement which makes the 16th century, next to the apostolic age, the most important period in church history. He acted a prominent part in all the leading events of the German reformation, and is inferior only to Luther and Calvin among the reformers. His constitutional modesty, gentleness, and peacefulness stand in strange contrast with the fiery contest into which he was reluctantly drawn. But, while Luther had to brace up his courage and to arm himself for the conflict, Melanchthon was admirably adapted to restrain the fiery zeal of his elder colleague, and to lend him the aid of his superior, well digested, and orderly learning. In 1519 he attended the Leipsic disputation, and defended Luther by his pen against Dr. Eck, the champion of the church of Rome. In 1521 he published the *Loci Communes*, the first system of evangelical Protestant theology, which passed through more than 50 editions during his lifetime, and was used long after his death as a text book in the Lutheran universities. At first it was but a fresh effusion of the vigorous evangelical faith in the Scriptures and the all-sufficient grace of God in Christ; but subsequently it was greatly enlarged and improved, although

it never attained the philosophical depth, logical order and precision, polished elegance, and scientific perfection of Calvin's "Institutes." In 1522 and the following years he wrote several commentaries which created an epoch at the time, but were overshadowed afterward by some of Luther's and especially by Calvin's commentaries, and are less valuable in a philological point of view than we might expect from so eminent a Greek scholar, who wrote Greek even easier than his native German. He also lent valuable aid to Luther in the translation of the Bible, which was commenced in 1522 and completed in 1534. In 1527 he visited the churches of Saxony with a view to correct abuses and to introduce various reforms. In 1529 he accompanied his prince to the diet of Spire, and helped to draw up the famous protest of the evangelical minority against the Catholic majority of the diet, which gave rise to the name Protestants. In the same year he attended the unsuccessful theological conference with the Zwinglians at Marburg. At that time he agreed with Luther's view on the Lord's supper. In 1530 he spent several months at Augsburg during the session of the diet, and wrote with unusual ability, conscientious care, calm moderation, and practical wisdom, his most important official work, the "Augsburg Confession," which was signed by the Lutheran princes, publicly read before the diet, and became by general consent the principal symbolical book of the Lutheran denomination. Soon afterward he replied to the "Refutation" of the Roman divines by the "Apology of the Confession," a work of great theological merit, and likewise of symbolical authority in the Lutheran church, though far less used and quoted than the Confession. Subsequently he made considerable modifications and alterations in the Confession, with the view to improve and to adapt it to the Reformed churches. Hence the difference between the "Altered" Augsburg Confession of 1540, and the "Unaltered" of 1530. The principal change refers to article X. on the Lord's supper, and the omission of all those words which favored the view of the corporeal presence and an oral fruition of the body and blood of Christ by all communicants. The changes were first passed by or acquiesced in, but subsequently gave rise to violent controversies. In 1536 he endeavored, with Bucer of Strasbourg, to bring about a doctrinal compromise between the Lutheran and Zwinglian views on the Lord's supper. In 1537 he signed the "Articles of Smalcald," drawn up by Luther, but added the singular proviso that he would acknowledge the supreme authority of the pope *jure humano*, if he would tolerate the freedom of the gospel; i. e., he was willing to become a semi-Catholic, if the pope would become a semi-Protestant. In all the conferences with the Roman Catholics, at Worms (1540), and at Ratisbon (1541), he was the delegate of the Lutheran party. In these conferences, and especially in the adiaphoristic controversy concerning the Augsburg and the Leipsic Interim

(1547), he incurred the censure of the more determined Protestants. His motives were always disinterested and praiseworthy; yet his constitutional timidity, modesty, love of peace, and the hope of an ultimate reconciliation of Catholicism and Protestantism, which he probably cherished to the end of his life, led him to make too many concessions, and to agree to compromises which satisfied neither party and were soon broken up. This compromising disposition, his doctrinal changes on the Lord's supper and other articles, together with various personal causes, disturbed his relations with Luther, of whose overbearing disposition and capricious humor he often complained in confidential letters to Camerarius and others. He even speaks once of a *servitus deformis* which he had to bear. Yet their friendship, based as it was on mutual esteem and affection, as well as equal zeal for the reformation, was never entirely dissolved. Luther, though often dissatisfied with Melancthon's timidity and vacillation, never openly took ground against him; and Melancthon, in his funeral oration on Luther, though not expressing himself with that warmth of feeling which he displayed 10 or 20 years before, called him the Protestant Elijah, and lamented his death as a great calamity for the church of Christ. From Luther's decease in 1546 to his own death in 1560 Melancthon was the acknowledged leader of the German reformation, and was consulted by princes and universities in all important events and measures. In the mean time the Lutheran divines became more and more (and are to this day) divided between two schools, the strict old Lutherans, headed by Flacius, Amsdorf, Hessus, and other violent polemics against Roman Catholics as well as Calvinists, and the more moderate, conciliatory, and progressive Melancthonians, or Philippists, as they were generally called, after the Christian name of their leader. Melancthon bore the violent abuse of his former friends and pupils with exemplary patience and meekness. What he lost in the confidence of the zealots for exclusive Lutheranism he gained in esteem and confidence with the Reformed churches in and out of Germany. He stood in friendly correspondence with Calvin to the last, and was invited to England. In 1551 he set out for the council of Trent as delegate from Saxony, when Maurice suddenly changed the aspect of affairs by his famous military stratagem against the emperor and dispersed the council. The peace of Augsburg in 1555 materially improved the political condition of the Lutherans, and secured to them liberty of worship within the German empire. In 1557 he attended, at the request of the emperor, the last theological conference with the Roman Catholics at Worms. He was received with great honor, but the conference ended in a complete failure, and the hope of reconciliation utterly vanished. This, in connection with the violent eucharistic or crypto-Calvinistic and other doctrinal controversies in the Protestant party, which made him so often with

for deliverance *a rabie theologorum*, the unsparing attacks of the strict Lutheran party, and various domestic afflictions, greatly embittered the last years of his life, and broke down his weak physical frame, already exhausted by incessant study and application. Nevertheless he continued to write *responsa et vota* to the last. A few days before his death he wrote in Latin on a piece of paper on his desk the reasons which made the king of terrors a welcome messenger of peace to him, viz.: on the left side, deliverance from sin and from the acrimony and fury of theologians; on the right side, the light of eternity, the vision of God and his Son, and the full knowledge of those wonderful mysteries of faith which we can but imperfectly understand in this life. On an official journey to Leipsic in March, 1560, he contracted a cold which proved fatal. His last and greatest care and sorrow was the distracted condition of the church; his last and most fervent prayer, the unity of believers, in the words of the Saviour, that they may be perfected in one even as he is with the Father. When Peucer, his son-in-law, asked him whether he desired any thing, he replied: "Nothing but heaven;" and soon afterward he breathed his last. He was buried in the principal church of Wittenberg by the side of Luther.—As a reformer, Melancthon was admirably adapted to complete Luther, and to assist him in his work. He differed from him as the quiet stream of the meadow from the wild mountain torrent, as the gentle breeze from the thunder storm, or as the gentle St. John from the fiery St. Paul. He was more a man of thought than of action, and better suited for the quiet study than the commotion of public life. Greatly Luther's inferior in strength of intellect and will, he surpassed him in scholarship and moderation of spirit. The one was the hero, the other the theologian of the German reformation. He reduced the new ideas to order and system, and commended them to literary men, while Luther powerfully impressed them upon the people. Luther was the most warlike and commanding, Melancthon the most peaceful and amiable of the reformers. The one gave free vent to his uncontrollable passions, and indulged often in the most violent and contemptuous terms; the other expressed himself always in gentle, scholarly, and courteous language, speaking in "the still small voice" after the thunderstorm had spread terror and desolation. He was modest and timid even to a fault, yet not cowardly; he lacked only the aggressive positive courage of heroic natures, but had the passive courage of self-control, self-denial, silence, and endurance. Luther stood firm as a rock against the pope and the emperor. Melancthon felt most painfully the evils of the schism, and was always ready to make any concession consistent with principle to restore peace and harmony. "If my eyes," he said on one occasion, "were a fountain of tears, as rich as the waters of the river Elbe, I could not sufficiently express my sorrow over the divisions and distractions of Christendom."

The *pax, concordia, tranquillitas ecclesie* constantly occur in his writings as the greatest desire of his heart. He was truly a man of peace in the midst of war, and a man of union in the midst of discord. He represents also the union tendency within Protestantism itself, and acted, especially in the latter part of his life, as a theological mediator between the Lutheran and the Reformed Calvinistic confession. The formal ecclesiastical union of the two churches in Prussia, Württemberg, Baden, and other German states since 1817, is to be attributed in great measure to the influence of the Melancthonian spirit, which was violently suppressed in the 17th century, but powerfully revived in the 19th. Luther has admirably characterized both himself and his friend in the following words of the year 1529: "My mind, being untrained in the liberal arts and unpolished, is constantly spitting out volumes of words. I am rough, boisterous, stormy, and altogether warlike, born to fight innumerable monsters and devils, to cut down stumps, to remove stones, to burn thistles and thorns, and to clear the wild forests; but Master Philippus (so he generally called Melancthon) comes along softly and gently, sowing and watering with joy, according to the rich gifts which God has bestowed upon him." In 1580, during the diet of Augsburg, Luther wrote to his friend: "I am somewhat weak in private matters, and you are stronger; but in public affairs you are weaker and I am stronger. You say, you could easily lay down your life, but tremble for the state of the church. I am well contented and perfectly at ease as regards the course of events, knowing that Christ is abundantly able to defend his cause." Melancthon was of small stature, and of tender, delicate frame, but had a fine blue eye and noble forehead. He married in 1520, by the strong advice of his friends, the daughter of the burgomaster of Wittenberg, and lived happily with her till her death in 1557. He called his nursery the "little church" (*ecclesiola Dei*), and was occasionally seen by visitors rocking the cradle with one hand and holding a book in the other. He cared little or nothing for money, was extremely good-natured and benevolent, and unblemished in all his moral relations.—The works of Melancthon reveal the extent of his scholarship, his rare talents, immense industry, and fine taste. They embrace a Greek and Latin grammar, editions of and commentaries on several classics and the Septuagint, biblical commentaries, doctrinal and ethical works, official documents, declamations, dissertations, responses, and a very extensive correspondence with friends and the leading men of the age. The first edition of his collected works appeared at Basel, in 5 vols. fol., in 1541; the second under the editorial care of Peucer, his son-in-law, at Wittenberg in 1562-'4; but both are incomplete. The last and most valuable edition is that of Bretschneider and Bindseil in the *Corpus Reformatorum* (28 vols. fol., 1884-'60). The life of Melancthon has been written by his friend Camerarius (1566), and in

the present century by Niemeyer, Köthe, Ledderhose (Heidelberg, 1847; translated into English by Krotel), Galle (1840), Matthes (1841), and Wohlfahrt (1860). But a full and satisfactory biography, like that of Luther by Jürgens, is as yet a desideratum in German literature.—On April 19, 1860, the tricentennial celebration of Melanchthon's death was held with great enthusiasm throughout Protestant Germany. At Wittenberg, where "he lived, taught, and died" (as the inscription on his house reads), the corner stone of a noble monument to his memory, to be erected at the side of that of Luther, was laid on that occasion by the prince regent of Prussia in the name of the king. The festival oration was delivered by the venerable Dr. Nitzsch of Berlin, the last surviving professor of the once famous university of Wittenberg. At the same hour the foundation of a similar monument was laid at Bretten, the birthplace of the *præceptor Germaniæ*.

MELANESIA. See MICRONESIA.

MELANOSIS (Gr. *μελανω*, to become black). For a long time melanosis was looked upon as a distinct disease, and melanotic tumors formed a class by themselves. This is no longer the case, and it is now believed that melanosis (the deposit of a black pigment) may occur in any of the textures, natural or morbid. It is thus found in the lungs, in the bronchial and mesenteric glands, in the sympathetic ganglia, as well as mixed with new deposit as cancer and tubercle. The coloring matter is generally thought to be derived from the hematine of the blood. The black deposits in the air cells of miners is a mere accumulation of carbonaceous dust.

MELAS. See CEFISSIA.

MELAZZO (anc. *Mylæ*), a seaport town on the N. coast of Sicily, in the province of Messina, 20 m. W. from Messina, built on a promontory which forms a spacious bay, the *Basilicus Sinus* of the ancients, affording excellent anchorage; pop. about 7,000. It is divided into two parts, one on the promontory strongly fortified, and the other at the harbor near the bottom of the bay. The exports are wine, oil, olives, and fruits of every kind. Many of the inhabitants are employed as sailors and fishermen, the tunny fishery being considerable. The plain of Melazzo, bounded by the mountains of Pelorus, is renowned for its beautiful scenery. The promontory of *Mylæ* was the scene of a victory of the Roman fleet over that of the Carthaginians in the first Punic war, 260 B. C., gained by means of the engines called *corvi*, then used for the first time. In 86 B. C. Agrippa, the commander of Octavian's fleet, defeated there that of Sextus Pompey. In 1719 Melazzo was unsuccessfully besieged by the Spanish army. On July 20, 1860, a brilliant victory was achieved at Melazzo by Garibaldi over the Neapolitans under Col. Bosco, resulting in the evacuation of the town and citadel by the latter. Fifty guns, 139 horses, and 100,000 rounds of ammunition were taken by the troops of Garibaldi; but the most important consequence of

the battle was that it opened the gates of Messina to the revolutionary forces.

MELBOURNE, the capital of the British colony of Victoria in S. E. Australia, on the banks of the Yarra-Yarra river, about 9 m. from its mouth, at the upper end of the large estuary of Port Phillip, 587 m. S. S. W. from Sydney; lat. 37° 48' S., long. 144° 58' E.; pop., including suburbs, about 140,000. The principal part of the town is on the N. side of the river, but some wards lie on the S., where South Melbourne, Sandridge, St. Kilda, and the W. part of S. Yarra are comprised within the city boundary. N. and S. Melbourne are connected by a bridge. On the N. side the chief part of the town lies in a valley with its extremities carried over two hills. The S. side is flat and swampy, excepting the sandy margin of Hobson's bay, where Sandridge stands. The streets of Melbourne are mostly laid out at right angles, wide, straight, and running the whole length or breadth of the town. They are macadamized in the centre, well drained, mostly flagged at the sides, and lighted with gas. In the original plan of the city lanes alternating with the main streets were left with the idea of their affording private back entrances to the houses situated in the former; but as the value of property increased these lanes were occupied by merchants and tradesmen, became independent streets, and form a very unsightly feature in the older part of Melbourne. If we except temporary erections of wood and iron, which were put up during the first years of the movement to the gold diggings, and which are gradually being replaced, the town is well built of brick and stone. The great number of laborers and seekers of fortune of all nations, including Germans, French, and Chinese, add considerably to the animated appearance of the city. The principal streets are constantly crowded with cabs, carts, and vehicles of every description. Collins street is the Broadway of Melbourne, and about $\frac{1}{2}$ wider than the great thoroughfare of New York. Melbourne became the seat of a bishop in 1847 (in 1860, Charles Perry, D.D.). The most numerous churches are those of the church of England, Wesleyans, and Roman Catholics, and there are also places of worship for Independents, Lutherans, Baptists, and other Protestant denominations, as well as for Jews. The new Wesleyan church, opened in Aug. 1859, is said to be one of the handsomest church edifices belonging to that denomination in the world. The city contains 9 banks, 8 theatres and a circus, an exchange, a court house and public offices, a very substantial market place, a government house, a great number of handsome shops and warehouses, beside many very elegant private residences. The exterior of the new parliament house is not yet completed. The cost of the building, when finished, will not be much below £1,000,000. There is a hospital for both in and out door patients, a benevolent and lunatic asylum, and other charitable institutions. The university of Mel-

bourne was opened April 18, 1855. It is built from the designs of Mr. F. M. White, upon a fine site to the N. of the city, and has 40 acres of land attached, forming part of extensive pleasure grounds. The form of the building is that of a parallelogram, the 4 sides facing the cardinal points, with a quadrangle in the centre. It is open to all classes of British subjects without any religious tests. It has professorships for the classics, mathematics, modern history, and natural science. The number of national and private schools in 1860 was upward of 200, and is constantly increasing. There are also scientific and literary associations, and the public library is among the finest public buildings; its large hall is supported by Corinthian columns and paved with tessellated marble. The average attendance is 200 daily. Another wing is to be added to it, and the colonial government has granted £20,000 for that purpose. The number of books is about 8,000. The legislature voted in 1859 and 1860 respectively £5,000 for the purchase of new books. The principal journals are the "Age," "Herald," and "Argus." The new post office, opened in 1859, is a magnificent building in the Italian style, elaborately adorned with sculptures; it stands on the corner of Bourke and Elizabeth streets. The principal façade, which is on Bourke street, is broken by 4 towers; and in one of the corner towers, which rises a story higher than the others, there is a clock with 4 dials. The Yan Yean water works were opened Dec. 31, 1857, being the greatest engineering works in which the colony of Victoria ever engaged. The reservoir is formed in a valley among the Plenty ranges, by confining the water of the river by an embankment 8,159 feet long, 81 feet high, 170 feet in thickness at the bottom, and tapering to only 20 feet at the top. The inside of this embankment is a wall 30 feet thick at the bottom and 10 at the top. From this lake the water is carried through iron pipes to Melbourne, a distance of about 18 m. The lake is 25 feet deep and 10 m. in circumference. The valve house in Carlton gardens allows the water to flow direct into all parts of the city. There are several pleasure grounds in the immediate neighborhood of the city, the chief of which are the royal park, the police paddock, and the Carlton and Fitzroy gardens. Collingwood, Brighton, Richmond, St. Kilda, and other suburbs of Melbourne are studded with beautiful villas and terraces. The number of houses given in 1857 is 10,884, at the average yearly rental of \$450 for each house.—There is a steam mail service established with England, via the isthmus of Suez, once a month, and regular communication is maintained with all the neighboring colonies by very efficient steam vessels. Good roads extend to all the principal gold fields; there is a railway to Geelong, and several other railways are in course of construction to bring the produce of the far interior to Melbourne. The climate is on the whole cooler than is generally experienced in

the same latitude N. The mean temperature of January (midsummer) is 66°, the highest 101°, and the lowest 48°; while the daily average of the month is 19°. There is a great proportion of dry sunny weather. The annual fall of rain, taken from the mean of 5 years, gives 32.63 inches. The wettest months are those from April to November inclusive.—In commerce Melbourne ranks as the first port in the British colonial possessions and of the southern hemisphere. This importance is due to the gold discoveries in 1851. The trade of Melbourne is carried on with all the principal ports of the world, and the imports consist, with trifling exceptions, of every article of necessity or luxury used by civilized man. Beside gold, the chief exports are wool, tallow, hides, and other kinds of raw produce. Gold is in proportion to the other exports about $\frac{1}{3}$ of the whole amount. The exports of Melbourne in 1856 amounted to £14,868,250. The total value of the trade, both export and import, was in 1857 about £31,000,000; and the vessels entering the port measured in the aggregate 800,000 tons. During the 8 months ending March 31, 1859, the imports amounted to £3,880,640 (declared value), and the exports to £3,279,288; and during the same period in 1860 the imports were £4,046,584, and the exports £2,992,105. The export of gold from Melbourne for the last 5 years has been as follows: 1855, 2,576,745 oz.; 1856, 3,003,811; 1857, 2,729,655; 1858, 2,586,988; 1859, 2,280,525. The receipts at the Melbourne custom house for the year ending March 31, 1859, amounted to £2,961,265, and for the year ending March 31, 1860, to £3,261,143. The commerce of the United States with Melbourne comprised in 9 months ending June 30, 1858, an aggregate of 90 vessels. Ships drawing 24 feet of water can come up Port Phillip as far as Hobson's bay at the mouth of the Yarra Yarra; but vessels requiring more than 9 feet of water cannot get over the bars. Although the distance to the bay by the course of the river is 9 m., it is not quite 2 by land, and a railway with an extensive jetty at its lower terminus has been made, connecting Melbourne with Port Phillip at Sandridge. There is another railway to Williamstown, on the opposite side of Hobson's bay, which, though considerably longer, has the advantage of better shelter for ships lying at the jetty. A ship railway has been constructed here capable of taking up vessels of very large size. From the anchorage in Hobson's bay to the Heads of Port Phillip the distance is about 35 m., and the channels are obstructed part of the way by sand banks which render the assistance of experienced pilots necessary. The Heads, or the opening connecting Port Phillip with Bass's strait, is about 2 m. across, but this is occupied by foul ground on either side, which leaves a channel for shipping of little more than a mile broad. Through this narrow passage the ebb and flood tides sweep over the uneven bottom with great force, and raise a sea which, when

the wind happens to be fresh from the opposite direction, is exceedingly dangerous and often fatal to small or dull-sailing craft. Strong fortifications are at present in course of construction upon the points of land, Lonsdale and Napein, at either side of the entrance. The rise and fall of the tide is about 8 feet. Melbourne possesses steam flour mills, tallow boiling establishments, brass and iron foundries, and other industrial establishments.—The site of Melbourne was selected and occupied by a small colonizing party from Tasmania, or Van Diemen's Land, in 1835. Two years afterward the town was officially recognized and named in honor of Lord Melbourne, the British prime minister, by the government of New South Wales, to which colony Melbourne, together with the surrounding country, then called the Port Phillip district, belonged until its formation into a separate colony in 1851 under the name of Victoria. In 1852 Melbourne became the seat of a legislative assembly.

MELBOURNE, WILLIAM LAMB, viscount, a British statesman, born in London in 1779, died Nov. 24, 1848. He was the eldest son of the first Viscount Melbourne, and after an education at Trinity college, Cambridge, and the university of Glasgow, was in 1804 called to the bar at Lincoln's Inn. In 1805 he entered parliament as a supporter of Fox and the whigs, a connection which he steadily maintained during his political life. In 1812 he was returned for Westminster, and in 1827 was appointed secretary for Ireland. In 1828 he succeeded to his title, and took his seat in the house of lords, and two years later he entered the cabinet of Earl Grey as home secretary. Upon the retirement of the latter in 1834 he became the first lord of the treasury, in which position he remained, with the exception of a brief period in 1834-'5, when Sir Robert Peel temporarily assumed the premiership, until 1841, when he was again succeeded by Peel. His administration was distinguished by no important political event, but was rendered permanent and popular by the tact and personal qualities of the premier.—CAROLINE (PONSONBY), known as Lady Caroline Lamb, wife of the preceding, born Nov. 18, 1785, died in London, Jan. 26, 1828. She was the only daughter of the 8d earl of Beesborough, and at 20 years of age, being then remarkable for her grace of manners, intellectual culture, and genius, was married to the future premier, who was then just commencing his political career. Having tastes congenial with those of her husband, she shared with him the classical studies in which they were both proficient, and also made herself mistress of several of the modern languages. In 1816 she appeared before the public as the authoress of "Glenarvon," a novel of which the hero was supposed to shadow forth the character and sentiments of Lord Byron, for whom about 1818 she had conceived a romantic but unfortunate attachment, which was long the theme of comment in fashionable circles in London. The poet, wearying

finally of her admiration, severed his relations with her in the well-known lines to her written a short time before his departure from England. Notwithstanding this attack, she still cherished feelings of regard for him; and it is related that, coming suddenly upon the hearse which was conveying the remains of Byron to Newstead abbey, she fainted on the spot, and was for some time afterward prostrated by a severe illness. For many years she lived in seclusion in Bocket hall, and about 8 years before her death was separated from her husband, who however continued to visit and correspond with her, and of whom she never spoke but in terms of admiration. She published two other novels, "Graham Hamilton" and "Ada Reis."

MELCHISEDEK ("king of righteousness"), according to Gen. xiv. 18, a "priest of the most high God" and "king of Salem," went forth to meet Abraham on his return from the pursuit of King Chedorlaomer, brought "bread and wine" for the warriors, and blessed Abraham, who in return gave him a tenth of the spoils. One of the Psalms (cx. 4) contains the words, "a priest after the order of Melchisedek;" and the Epistle to the Hebrews (vi. 20, vii. 1-22) represents him as a type of Christ, and his office as superior to the Aaronic priesthood. The opinions of theologians as to the person of Melchisedek and the nature of his priesthood have at all times greatly varied. With regard to his residence, they are now generally agreed that Salem was the original of Jerusalem. In the ancient church, a sect, called Melchisedekites, regarded Melchisedek as an incarnation of a divine power, and as superior to Christ.

MELCHTHAL, ARNOLD VON, a Swiss patriot, born in the canton of Unterwalden in the latter part of the 18th century. His real name was Arnold von der Halden, but he was generally known by the name of Melchthal, in which place he resided. The servant of the Austrian governor Von Landenberg having one day seized a yoke of oxen belonging to Arnold's father, the young man struck the menial to the ground and fled to the mountains. His father, declining to disclose his place of refuge, was blinded by order of the governor; and this cruel deed, which has been beautifully dramatized in Schiller's "William Tell," became the signal of revolution. Young Melchthal, in his retreat to the Rütli, was joined by Fürst of the canton of Uri and Stauffacher of the canton of Schwyz, with whom, one night in Nov. 1807, on the shore of Lake Lucerne, he took an oath to devote his life to the cause of Swiss independence, which was achieved in Jan. 1808, by the expulsion of the Austrians from the 8 cantons above named, and the destruction of their castles, without bloodshed. The authenticity of the whole account, however, which is given according to an ancient Swiss chronicle, has been much disputed of late years. Arnold von Melchthal has sometimes been confounded with Arnold Winkelried, another Swiss hero, who fell at the battle of Sempach, July 9, 1386.

MELCOMBE, LORD. See **DODINGTON**.

MELEAGER. I. A mythical hero of Greece, and one of the Argonauts. II. A Macedonian general who served under Alexander the Great. At the battle of the Granicus, 334 B. C., he commanded one of the divisions of the phalanx; and in almost all the Asiatic campaigns he appears to have held the same office. On the death of Alexander he was associated in the regency with Perdikkas, but was subsequently put to death by order of his colleague. III. A Greek epigrammatist, who flourished about the middle of the 1st century B. C. He was a native of Gadara in eastern Palestine, and made a collection of epigrams, entitled *Στεφανος Επιγραμματων*, from over 40 authors. This work has perished, but we still possess 131 of his own epigrams, which form part of the Greek anthology. The best separate edition of Meleager is that of Gräfe (Leipsic, 1811).

MELEGNANO, MARIGNANO, or MARIGNAN, a town of Lombardy, in the district of Milan, on the Lambro, 11 m. S. E. from Milan and 10 m. W. N. W. from Lodi; pop. about 4,000. It was destroyed by the emperor Frederic II. in 1239; and the Guelphs and Ghibellines signed a treaty of peace there in 1279.—In Sept. 1515, it was the scene of a famous battle between Francis I. of France and the Swiss in the service of the duke of Milan, which is sometimes called, from its obstinacy and the superior character of the troops on both sides, the "battle of the giants." The attack was made by the Swiss late in the afternoon of the 13th, with such impetuosity that the French were driven from their intrenchments and lost a part of their artillery. Rallying, however, under the inspiring conduct of the king, they soon recovered their ground and maintained the contest until the night was far advanced. A truce then ensued for a few hours. At the dawn of day the battle was resumed, the Swiss again being the assailants; but their charge this time was repelled with unshaken firmness, and Francis at the head of his men-at-arms then threw himself upon their line, and for a while caused it to waver. It may be doubted, however, whether he would have proved the victor had not D'Alviano rushed into the midst of the fight with a small body of cavalry, and shouting the war cry of *Marco* animated the French with the belief that their Venetian allies had come to their assistance. The Swiss, after supporting the contest for several hours, withdrew to Milan, but in such order that the conquerors did not venture to pursue them. The losses are variously stated—that of the Swiss from 8,000 to 15,000; that of the French from 3,000 to 8,000. The chevalier Bayard distinguished himself on the field by feats of extraordinary bravery; and Francis, who throughout the action had given many proofs of courage, insisted upon being knighted by him on the spot.—Another French victory was gained here, June 8, 1859. On the occupation of Milan by the French and Sardinians after the battle of Magenta, the Austrians re-

treated toward Lodi, holding Melegnano with about 18,000 men in order to cover their line of march. The emperor Napoleon ordered Marshal Baraguay-d'Hilliers at the head of the 1st army corps, assisted by the 2d corps under Marshal McMahon, to dislodge them; and in accordance with these instructions McMahon's troops advanced in two divisions in such a manner as to turn the position, while Baraguay-d'Hilliers, with his men disposed in 3 columns, marched along the main road. On reaching the town he found the Austrians posted behind a barricade with a battery planted on an eminence which commanded the approach, and riflemen in nearly every house. The artillery began the battle and played for about an hour, when a battalion of Zouaves, followed by the whole 1st brigade, charged upon the Austrians and drove them into the town. Here a desperate hand-to-hand conflict was maintained from 7 till 9 o'clock in the evening, ending with the complete rout of the Austrians. Marshal McMahon's corps arrived in time to inflict great loss upon the retreating enemy, but the victory was followed by no important result. The French, by their own account, had 16,000 men in the field, and lost 943, while the Austrians lost 2,800.

MELENDEZ VALDEZ, JUAN ANTONIO, a Spanish poet, born in Ribera del Fresno, Estremadura, March 11, 1754, died in Montpellier, France, May 24, 1817. He was educated at the university of Salamanca, where he became professor of belles-lettres. In 1780 he obtained a prize offered by the Spanish academy for the best eclogue, on which occasion he had Yriarte for a rival. He afterward held various official stations, and when Joseph Bonaparte became king of Spain, attached himself to the French party, and shared in its misfortunes. Once he was led out to be shot by the populace of Oviedo, whither he had been sent as a commissioner. Finally he fled to the south of France, where he lived for 4 years in misery, his death having been hastened by the want of means to purchase substantial food. His poems embrace odes, eclogues, idyls, and pastoral dramas, of which the most popular is "Camacho's Wedding." His collected works, with a life by Quintana, were published at Madrid in 1820.

MELETIUS, or, as Athanasius and others call him, **MELITUS,** bishop of Lycopolis in the Egyptian district of Thebais, flourished about the beginning of the 4th century. He disagreed with Peter, bishop of Alexandria, concerning the readmission of the *lapsi* to the church, and encroachments upon the rights of other bishops, especially that of Alexandria. The accounts given by ancient writers of the origin and nature of this controversy are very contradictory, and the church historians are not yet agreed what part of the ancient account should be taken as true, and what part ought to be rejected. It is generally admitted that the Meletian schism arose between 308 and 305. The council of Nice censured Meletius, and forbade him to ordain any priests in future; but

the title of bishop was left to him, and those who had been ordained by him were permitted to retain their offices. At the time of the council of Nice the party of Meletius counted 29 bishops, and in the city of Alexandria itself it had 4 priests and 8 deacons. The hope of the council to bring the Meletians back to a union with the Catholic church was not fulfilled. They soon after united with the Arians against Athanasius, and are mentioned as late as the middle of the 5th century.

MELETIUS, bishop of Antioch, born in Melitene, Armenia Minor, about the beginning of the 4th century, died in Constantinople in 381. Little is known of his early life. He was first bishop of Sebaste, which see he resigned on account of the stubborn conduct of the people. He then lived in retirement at Beroea (according to another statement he was bishop there) until 360, when he was elected bishop of Antioch. That church was greatly disturbed by the Arian controversy. The bishop Eustathius, an adherent of the council of Nice, had been deposed in 380 through the influence of the Arians. His followers existed as a separate party, under the name of Eustathians, while the Arians were themselves divided, the ruling party, which was on the whole Arian, in opposition to Semiarrianism, bearing the name of Acazians. Meletius was so highly esteemed, that he was elevated to the episcopal see by general consent. Yet soon after his inauguration he offended the Acazian party by a discourse, which, though it did not adopt the Athanasian expressions, yet leaned toward the orthodox (Nicene) party. Meletius had to leave Antioch, and a strict Arian, Euzoius, was elected in his place. But one portion of the diocese adhered to Meletius and seceded. This new organization, the Meletians, held a synod at Antioch in 368, at which they adopted the doctrines of the council of Nice, though only with an explanatory clause. Notwithstanding this advance toward the orthodox churches, the old Nicene party of the Eustathians continued its separate existence and was alone recognized by the western churches, in particular by Alexandria and Rome. Repeated efforts of Meletius to obtain his recognition by Rome failed, but in 380 his jurisdiction over all the Arian churches was restored. The connection of Meletius with the leading theologians of the eastern church, as Basil, Gregory of Nyssa, and others, gradually prepared the way for his recognition by the Nicene churches and for a compromise with the Eustathians. Meletius, instead of Paulinus, bishop of the Eustathians, appeared at the oecumenical council of Constantinople as the representative of Antioch; he was even regarded as one of the leading men of the council, and died before its close. After his death, the schism between the Meletians and the Eustathians continued. In 398 the successor of Meletius was recognized by Rome and the West; and in 415 the last members of the Eustathian sect joined the predominant church.

MELLI, GIOVANNI, a Sicilian poet, born in Palermo, May 4, 1740, died there, Dec. 20, 1815. He was a physician and professor of chemistry at the university of Palermo, and was the author of several scientific essays; but he is chiefly celebrated for his poetical compositions, which have procured him the titles of "the Sicilian Anacreon" and "the modern Theocritus." His love songs are extremely popular in Sicily. The most important of his poems, beside his odes and eclogues, are: *La fata galante*, his earliest effusion; *Don Chisciotte*; and *Origine del mondo*, a philosophical satire. A complete edition of his poetical works, edited by himself, appeared at Palermo in 1814, in 7 vols. 8vo.

MELITA. See MALTA.

MELLEN, GRENVILLE, an American poet, born in Biddeford, Me., June 19, 1799, died in New York, Sept. 5, 1841. The eldest son of an eminent chief justice of Maine, he was graduated at Harvard college in 1818, studied law in the office of his father, who had removed to Portland, was admitted to the bar, married, and removed in 1823 to the neighboring village of North Yarmouth, where he engaged in the practice of his profession. He had been a frequent contributor of verses to magazines and annuals, when in 1826 he pronounced in Portland before the peace society of Maine a poem on the "Rest of Empires." In 1827 he published a satire entitled "Our Chronicle of Twenty-Six," in 1828 delivered an anniversary poem before the Athenæan society of Bowdoin college on the "Light of Letters," and in 1829 collected from his prose contributions to periodicals a volume entitled "Glad Tales and Sad Tales." His principal collection of poems, entitled "The Martyr's Triumph, Buried Valley, and other Poems," was published at Boston in 1838. The "Martyr's Triumph" is in the Spenserian stanza, and is founded on the history of St. Alban; the "Buried Valley" describes the avalanche near the notch in the White mountains by which the Willey family was destroyed. Mr. Mellen resided about 5 years in Boston, and removed thence to New York, where in 1839 he began a "Monthly Miscellany," which was discontinued after a few numbers. His health was always feeble, and he died of consumption after a voyage to Cuba in 1840.

MELLONI, MACEDONIO, an Italian physicist, born in Parma in 1800, died of cholera in Portici, near Naples, Aug. 11, 1854. He first became professor of natural philosophy at the university of Parma, where between 1824 and 1831 he taught hygrometry. Political events having compelled him in the latter year to expatriate himself, he took refuge in France, and was appointed through the efforts of Arago a professor in the college of Dôle, in the department of the Jura. Repairing thence to Geneva he availed himself of the collection of scientific instruments of Prevost and De la Rive to make several important discoveries respecting the radiation of heat, which he presented in 1840 to the French academy of sciences. His contribu-

nication was received coldly by that body, but the discoveries which it embraced subsequently procured him the Rumford medal from the royal society of London. Having now taken a prominent place among European physicists, he was enabled through the influence of his friends Arago and Humboldt to return to Italy, and was appointed by the king of Naples director of the meteorological observatory then building on Mt. Vesuvius. Among the results of his labors at this institution was the discovery of heat in lunar light, which led to the determination of the analogy of radiant heat to light. Political troubles again interrupted his labors, and for his presumed sympathy with liberal principles he was in 1849 ejected from his post, and retired to a villa in the neighborhood of Portici. In 1850 he published the first volume of a work entitled *La termocrasi, o la colorazione calorifica*, containing an account of his theory of the "coloration of light," and of his experiments on the diffusion of heat by radiation, and particularly of its transmission through transparent media. Subsequently he gave much attention to the study of electricity, and combated the conclusions of Faraday with regard to the transmission of currents over submarine wires.

MELMOTH, WILLIAM. I. An English lawyer and author, born in London in 1666, died there in 1743. He was called to the bar in 1693, and appears to have been treasurer of Lincoln's Inn in 1730. He is chiefly known as the author of "The Great Importance of a Religious Life Considered," of which over 100,000 copies were sold during the 18th century. This treatise was first published anonymously, and was for some time attributed to John Percival, earl of Egmont. A new edition of it, with a memoir of the author, by Charles P. Cooper, was privately printed in London in 1849, and presented to the benchers of Lincoln's Inn. II. A scholar and author, son of the preceding, born in London in 1710, died in Bath, March 15, 1799. Though educated for the bar, the greater part of his life was passed in retirement. In 1742 he published 2 volumes of "Letters on Various Subjects," under the pseudonyme of Sir Thomas Fitzosborne. His other principal works are translations from Pliny and Cicero.

MELO, or MELLO, FRANCISCO MANUEL DE, a Portuguese and Spanish author, born in Lisbon, Nov. 28, 1611, died there, Oct. 13, 1666. He was educated for literature, but entered the army at an early age, attained the rank of colonel, and when the insurrection against Philip IV. broke out in Catalonia was sent thither, receiving a royal order to write the history of the war. This work, *Historia de los movimientos, separacion y guerra de Cataluña* (Lisbon, 1645), ranks as a classic in Spanish literature. Melo was in the great tempest of 1627, when the Portuguese fleet was wrecked and thousands were lost; for 12 years he was confined in a Portuguese prison under a false accusation of murder, and for 6 years was an exile in Brazil. When in 1640 Portugal was

separated from Spain, he entered the Portuguese service, and was employed in diplomacy. After returning home in 1648, he devoted himself to literature. Many of his works in Spanish and Portuguese are unpublished; but those already printed exceed 100 volumes. His most popular poems are embraced in the *Tres musas del Melodino* (Lisbon, 1649; Lyons, 1665).

MELODEON (Gr. *μελωδία*, melody), the name, at different times, of two or more unlike forms of musical instruments, but now appropriated to one of recent date, and so far excelling those before it as to be substantially a new invention. In this, externally resembling the piano, the notes are determined by touching the keys of a finger-board; each key, lifting a valve, allows a current of air from a bellows, worked meanwhile by the foot on a pedal, to agitate the corresponding one of a series of metallic free reeds; the compass is 5 to 7 octaves. The rocking melodeon, known in America since about 1825, was unsightly, tardy in sounding, and of harsh tone. Mr. Jeremiah Carhart (born in Dutchess co., N. Y., in 1815) conceived the plan of acting on the reeds by suction instead of blowing, and reversed, to this end, the bellows and reeds, inventing the present instrument in 1836. He thus secured prompt sounding, and a flute-like quality of tone; "voiced" the note by curving the reeds; and made many other improvements. In 1859, 22,000 of these instruments were manufactured in the United States.

MELON, the common name of the fruit of creeping vines, distinguished generally as muskmelons, watermelons, and citrons, originating, as it is supposed, in the East, and long cultivated both in warmer climates and in those where artificial heat is requisite to bring it to maturity. In the former the melon supplies the want of vegetation during the period of the year when other plants possessing cooling properties are disappearing on the approach of the intense summer heats; and in the latter, as for instance in England, the melon is brought to great perfection by hotbeds and similar artificial appliances to maintain the temperature it requires. The melon succeeds admirably in some portions of the United States; and even in the vicinity of Boston it arrives at perfection in ordinary seasons. According to Lindley, its leaves have an immense perspiratory power, so that they require a greater supply of fluid than those of most other plants; which accounts for the singular fact that the melon seems to thrive best when its roots find their way into water, as in the irrigated fields of Persia, in the floating islands of Cashmere, and the springy river beds of India. Such a supply of moisture is requisite under exposure to an intense sunshine, the heat and bright light of which decompose and alter the fluids of the plants and elaborate from them an abundance of sweet juices. Artificially treated thus, the result was a failure; and only by repeated experiment did Knight succeed in raising in England the sweet melons of Ispahan to a perfection hitherto unsurpassed. He discovered

that the moisture should be applied to the roots so as not to cool the surface of the soil in which they grew, and for this end the ground was covered with tiles between which the water was poured. Such precaution, with high artificial heat and strong light, rendered his efforts successful. The frequent thunder showers and the summer heat combined produce the same effect in the American climate.—The term melon is applied to the many varieties of one species, the *cucumis melo* of botanists, ranging from the soft, mealy-fleshed, and almost tasteless smooth-rinded muskmelon, of an elongated form, through the richly flavored cantaloupes of the same general form, to the delicious green-fleshed, globular kinds, with rough netted rinds, known under different local names, in which the flesh is more firm, fibrous, rich, and highly flavored. The cantaloupes, such as the netted and black or rock cantaloupe, are much esteemed; and the sort to which they are naturally allied is said to have originated from a place of that name about 15 miles from Rome, where melons have been cultivated since the time of the Mithridatic war, and to have been originally brought from Armenia by Lucullus. According to Burnett, this particular sort is now unknown there. Next to these come the Persian varieties, such as are cultivated to an unsurpassed perfection on the plains of Ispahan and in Bokhara. The tendency to “sport” or run into new forms by intermixture, makes it difficult to classify the melons; and the London horticultural society’s catalogue declares that it is not easy to fix upon any permanent characters. In the arrangement used by that treatise, the season or period of ripening, the quality of bearing, color and thickness of the rind, color of the flesh, and average weight of the fruit when well grown, are the characters employed. Cultivators and amateurs in America are not well agreed on the merits of varieties cultivated. Kenrick, in his “New American Orchardist” (Boston, 1835), enumerates about 80 kinds as particularly good. Downing, in his “Fruits of America” (New York, 1845), has made a simple arrangement of them into 8 classes, viz.: green-fleshed, yellow-fleshed, and Persian. He gives only 18 varieties as among the choicest kinds. The skill of the cultivator produces occasionally some new or superior sort.—The melon, muskmelon, or cantaloupe, has a prostrate, hirsute, annual stem; cordate-orbicular, somewhat angular and roughish leaves, borne upon petioles 2 or 3 inches long; axillary, shortly peduncled, yellowish flowers; oval or ovate-globular, longitudinally ribbed fruit; and simple tendrils. It belongs to the natural order *cucurbitaceæ*, which are tropical plants in respect to habitat, though adapting themselves under cultivation, like many other annuals, to a more temperate climate. Excellent as are the fruits of the melon, yet as a genus *cucumis* possesses the prevailing characteristics of deleterious qualities. Many valuable medicines are the products of species of these cucurbitaceous plants. In the United States the

climate most favorable to the melon is that of the middle and southern states. In these, melons can be raised as field crops; and in warm, dry soils, such as that of Long island and New Jersey, the product may be so large that even at low prices the crop is one of the most profitable. Except in the most northern states, the cultivation of the muskmelon and of its varieties is very easy. The fruit of the muskmelon is considered cooling and refreshing, though with some it proves difficult of digestion and liable to produce colicky symptoms. The green-fleshed varieties are generally the sweetest and most delicious, and can be eaten with the most impunity. A particular variety called the nutmeg, when pure and in perfection, is very excellent, melting, and has a very high musky flavor. Downing especially commends the Persian melons as being in this respect exquisite. They require, however, extra care to bring them forward, and the employment of the hot-bed to hasten the growth of the plants in the spring. Beside the above mentioned, there is a melon called *dampah*, cultivated in the East, and which has the property of keeping for a long time after being cut, if suspended in a dry warm room, and hence known in the south of Europe as the winter melon.—The watermelon (*citrullus vulgaris*, Schrader) was once considered a species of *cucurbita*, then transferred to *cucumis* by De Candolle, but now made a distinct genus. It belongs, however, to the same natural order, and possesses the same essential characters, being an annual, trailing, rather slender plant, branching somewhat, and extending its stems from 8 to 15 feet in length; its leaves are 5-lobed, ovate in outline, 8 to 6 inches long, borne on petioles 2 to 3 inches long; its tendrils are branched; its flowers axillary and pale greenish yellow; its fruit of a very large size, smooth and green, with a red or yellow core and black or reddish brown seeds. The cooling and refreshing juice with which it abounds renders the watermelon a universally favorite fruit for the hotter season of the year, when it occurs in perfection; and immense fields are devoted to its production in New Jersey and Long island, the mode of culture being the same as that of the muskmelon. About Boston it does not prove a difficult fruit to raise, ordinarily requiring rich, dry, and light soil, and some little care in planting. There are many varieties, some of which are most highly esteemed, such as the imperial, a productive sort from the Mediterranean, with fruit nearly round, rind remarkably thin, flesh solid to the centre, light red, crisp, and rich; the Carolina, a large common variety, with very large, oblong fruit, flesh of a deep red, hollow at the centre, seeds very black, of which a sub-variety with pale yellow flesh and white seeds is known; the Spanish, a rich excellent kind, with large oblong fruit, skin very dark, blackish green, somewhat marbled, flesh red, solid, rich, and sweet; and the mountain sweet, a sort in much repute among cultivators.—The citron, so called, is a

nearly allied plant, with leaves, stems, and fruit so closely resembling the watermelon that judging from external marks there is nothing to distinguish it. The fruit is, however, round in shape, the rind of a dark green, mottled with large irregular whitish spots, the flesh of a tough hard consistence and tasteless, the seeds black. It is employed in the making of sweetmeats and preserves, by removing the rind or skin and seeds, cutting the flesh into convenient bits, and boiling in sirup which has been flavored with ginger, lemon, or some agreeable article. Dr. Darlington conjectures that it may be the particular variety of the watermelon known as the *pastecca* of Seringe and De Candolle. Its cultivation is the same as that of other kinds of melons, and it is a common plant in gardens.

MELODY. See **MUSIC**.

MELOS. See **MIL**.

MELPOMENE, in Grecian mythology, the muse who presided over tragedy. She was a daughter of Zeus and Mnemosyne, and is generally represented as a young woman of grave countenance, arrayed in splendid garments, wearing the cothurnus with a wreath of vine leaves on her head, and having in one hand a sword or the club of Hercules, and in the other a crown or sceptre.

MELROSE ABBEY, a celebrated ruin, situated on the Tweed in the town of Melrose, Roxburghshire, Scotland, 87 m. from Edinburgh, and 32 S. W. from Berwick. It was founded in 1136 by David I., completed in 1146, and dedicated to the Virgin Mary, the first occupants being Cistercian monks, who were brought from Yorkshire in England. In 1322 it was destroyed by the English army of Edward II. retreating from a fruitless invasion of Scotland, but was soon after rebuilt by Robert Bruce substantially after the present design, and in a style of magnificence which ranks it among the most perfect ecclesiastical structures of the best age of Gothic architecture. In 1385 and again in 1545 it suffered severely at the hands of invading English armies; and during the period of the reformation, when its monks were scattered, its choicest sculptures were wantonly mutilated by iconoclastic zealots. In later times it has been despoiled of many of its stones to furnish materials for the construction or repair of other buildings. Notwithstanding the ravages of time and the destructive efforts of man, it remains at the end of 5 centuries one of the best preserved specimens of Gothic architecture in Great Britain; and so durable is the stone of which it is built that the most delicate ornaments wrought in it appear as sharply defined as if newly carved. The church, which is the only part of the ancient monastery remaining, stands in the midst of a wide and fertile landscape, renowned in border legend and song, and is built in the form of a Latin cross, 285 feet by 130, with a square tower 84 feet high in the centre, of which only the W. side and part of the N. and S. walls are standing. The pres-

ent entrance is by a magnificent Gothic portal in the S. transept, over which rises a window 24 feet in height by 16 in breadth, divided by 4 richly interlaced mullions, and surmounted by niches which formerly contained statues of Christ and the apostles. Other parts of the same transept are ornamented with sculptured forms of plants, animals, and men. In the S. wall of the nave are 8 small chapels, lighted by as many windows of exquisite design, and of which the 3 nearest the central tower retain their original Gothic roof, the remainder being roofless. On the E. side of the choir or chancel is a window in an excellent state of preservation, than which, says Sir Walter Scott, "it is impossible to conceive a more beautiful specimen of the lightness and elegance of Gothic architecture when in its purity." Other portions of the building still standing, such as the cloisters and parts of the aisles, exhibit the richest fancy in their tracery and adornments, the forms of leaves and stalks being so delicately carved that a straw can be thrust between their interstices. Within the walls of the abbey lie buried Alexander II. of Scotland, James, earl of Douglas, who fell at Otterburne, and many warriors of the house of Douglas, of Scott of Buccleugh, and of other famous border families. Here also, according to tradition, was deposited the heart of Robert Bruce, after the "good Lord James" Douglas had made his unsuccessful attempt to convey it to the Holy Land. Over the whole structure a halo of romance has been thrown by the genius of Scott, who passed his latter years at Abbotsford, 8 miles distant, and whose description of the abbey by moonlight in the 2d canto of the "Lay of the Last Minstrel," is one of the finest passages in the poem. For upward of a century and a half the abbey has been in the possession of the earls and dukes of Buccleugh, who in 1816 temporarily fitted up a portion as a parish church.

MELTON-MOWBRAY, a town of England, in Leicestershire, near the confluence of the Eye and Wreak, 16 m. N. E. from Leicester, and 105 m. N. N. W. from London; pop. in 1851, 4,391. It is the centre of a hunting district, and the seat of the Melton club, which meets here from November to March, and attracts such numbers of sporting characters, that stabling has been erected for over 800 horses. The royalists defeated a body of republicans here in 1644.

MELUN, capital of the French department of Seine-et-Marne, on the Seine, 28 m. by railway from Paris; pop. of the town in 1856, 7,050; of the arrondissement of Melun, 62,164. The principal manufactures are cotton, wool, linens, hardware, &c. In the neighborhood, which is remarkable for its fine scenery, is Fouquet's chateau of Vanx-Praslin, where the brilliant financier was arrested in the midst of a fête which he gave in honor of Louis XIV. The town was besieged by the Normans, and on several occasions by the English, who were finally expelled. At the beginning of the 12th cen-

tury Abelard, though very young, opened a school of philosophy in this town, which was at that time a favorite resort of the French court.

MELVILLE, ANDREW, a Scottish religious reformer, born in Baldov, Forfarshire, Aug. 1, 1545, died in Sedan, France, in 1622. He was educated at the university of St. Andrew's, and in 1564 repaired to the continent, and passed several years at Paris, Poitiers, and Geneva, alternately studying and teaching. In 1574 he returned to Scotland, and was appointed principal of Glasgow college, where he introduced important improvements. He took a prominent part in the theological controversies of his age, and in the establishment of Presbyterianism in Scotland. Toward the close of the year 1580 he was made principal of St. Mary's college in the university of St. Andrew's, and lecturer on theology and the oriental languages. In 1582 Melville opened an extraordinary meeting of the Presbyterian general assembly with a sermon, in which he vigorously opposed the absolute authority assumed by the court in ecclesiastical affairs. He assisted in drawing up the remonstrance against the policy of the court, subsequently presented to the king at Perth by a deputation of which he was the head. The earl of Arran, one of the council, being irritated at the bold tone of this document, asked fiercely: "Who dares subscribe these treasonable articles?" "We dare," replied Melville, and immediately seizing a pen, affixed his name to it. This was imitated by all his colleagues, and the council suffered them to depart uncensured. But within two years Melville was summoned before the privy council on a charge of treason for words uttered in the pulpit, and Arran exerted himself for his conviction. The accusation, however, could not be proved, and he was sentenced to imprisonment on the charge of irreverence toward the council; but he escaped to London, and returned to Scotland, on the fall of Arran, in Nov. 1585. In 1587, 1589, and 1594, he was chosen moderator of the general assembly; in 1590 he became rector of the university; and in 1595 he delivered, at the coronation of the queen, a Latin poem entitled *Stephaniskion*, which, being printed at the earnest solicitation of James VI., was read with admiration throughout Europe. He was accustomed to address the king with the utmost plainness upon his foibles and vanity; and being a member of a commission appointed in 1596 to remonstrate with regard to certain measures inimical to religion, he chided James so severely as to excite him to great anger, but finally subdued him and obtained every concession demanded. On James's accession to the English throne he continued his efforts to obtain control of the Scottish church, which had hitherto been thwarted in great part by Melville. In May, 1606, he and other leading Presbyterians were summoned to London under pretence of being consulted by the king and government upon Scotch ecclesiastical affairs. They obeyed, but soon discovered that they were not free

agents; and Melville, for having indited a Latin epigram expressive of his contempt for certain ceremonies he had witnessed at the royal chapel, was brought before the privy council, found guilty of *scandalum magnatum*, and committed to the tower, where he remained a prisoner till 1611, when, at the solicitation of the duke de Bouillon, he was liberated on condition that he should expatriate himself. Retiring to France, he there, through the influence of the duke, was appointed professor of theology at the university of Sedan, an office which he held till his death. Melville's earliest production was a volume of Latin poems, including a paraphrase of the "Song of Moses," and a portion of the book of Job (Basel, 1574). There is a MS. commentary by him on the Epistle of Paul to the Romans, still extant.—See the "Life of Andrew Melville," by Dr. McOrrie (2 vols. 8vo., 1819).

MELVILLE, HERMAN, an American author, born in New York, Aug. 1, 1819. He is a grandson of Thomas Melville, one of the "Boston tea party." His boyhood was passed chiefly in Albany and Lansingburg, N. Y., and Berkshire co., Mass., until he reached the age of 18, when he shipped before the mast on a vessel bound for Liverpool, and returned home in the same manner, with his appetite for adventure sharpened rather than appeased by the voyage. In 1841 he embarked for the Pacific, as a sailor, on a whaling vessel, in which he cruised for 15 months; but, unable to endure the harsh conduct of the captain, he deserted with one of his comrades at Nukahiva, one of the Marquesas islands. His plan was to throw himself upon the hospitality of a neighboring friendly tribe, but losing his way he wandered into the Typee valley, where the warlike people who take their name from the valley held him 4 months in an indulgent captivity. At the end of that time he was taken off by a boat from an Australian whaler, which conveyed him to Tahiti. He passed some time in the Society and Sandwich islands, and in 1843 shipped on board the frigate United States at Honolulu, and arrived in Boston in Oct. 1844. "Typee," a narrative of his adventures in Nukahiva, told in a spirited and graceful style, appeared in 1846 in New York and London, and achieved an immediate success. It was followed in 1847 by "Omoo, a Narrative of Adventures in the South Seas," which recounts his escape from Typee and subsequent voyage. "Mardi and a Voyage Thither," a philosophical romance which was less admired, and "Redburn," founded on the incidents of his first voyage, appeared in the same year. He married in 1847 a daughter of Chief Justice Shaw of Massachusetts, and resided for a few years in New York. In 1850 he removed to Pittsfield, Mass., where he divided his time between the cares of a farm and authorship, successively publishing "White Jacket, or the World in a Man-of-War" (1850), "Moby Dick, or the White Whale" (1851), "Pierre, or the Ambiguities" (1852), "The Piazza Tales" (1856), and "The Confidence Man" (1857). In "Patri-

nam's Monthly" he reproduced with various alterations the narrative of "Israel Potter" (reprinted in 1 vol., New York, 1855), a real character of the American revolution, whose adventures, as related by his own lips, were published by Mr. Henry Trumbull at Providence in 1824. In 1860 Mr. Melville sailed again on a voyage round the world in a whaling vessel.

MELVILLE, SIR JAMES, a Scottish soldier, statesman, and author, born at Raith, Fifeshire, about 1535, died at Hal-hill, in the same county, Nov. 1, 1607. At the age of 14 he went to the continent, where he occupied various official stations until 1564, when he returned to Scotland, and presented himself at the court of Queen Mary Stuart, who appointed him to office, and settled on him a pension of 1,000 marks. After the murder of Darnley he remonstrated with her on her partiality for Bothwell, whereupon he lost favor and retired from public life. On the accession of James he was made a gentleman of the bedchamber and a member of the privy council, and was even pressed by the king to accompany him to London, when he went to take possession of the throne of England. Melville however declined this invitation, and devoted his latter days to the composition of his "Memoirs of Sir James Melville of Hal-hill, containing an Impartial Account of the most remarkable Affairs of State during the last Age." The earliest edition of these "Memoirs" appeared in London in 1688; the latest and best in Edinburgh in 1827.

MELVILLE, VISCOUNTS. See DUNDAS, HENRY, and ROBERT S.

MELVILLE ISLAND, an island lying off the N. W. coast of Australia, between lat. $11^{\circ} 8'$ and $11^{\circ} 56'$ S. and long. $180^{\circ} 20'$ and $181^{\circ} 24'$ E.; area, about 1,800 sq. m. It is separated from the mainland on the E. by Dundas strait, which is 15 m. wide, and on the S. by Clarence strait and Van Diemen's gulf; while on the W. it is severed from Bathurst island by Apsley strait. The N. coast is low, and indented with shallow bays, but elsewhere the coast is high and precipitous. The greater part of the island is in wood. Alligators and turtles abound on the coasts. The climate from October to May, owing to the great heat and humidity of the atmosphere, is unhealthy, but from May to October it is salubrious. The natives are chiefly hunters, and appear more athletic and enterprising than those of Australia.

MELVILLE SOUND, or PARRY SOUND, a body of water in the north polar regions of America, lying between lat. 72° and 75° N. and long. 100° and 115° W., enclosed between the Parry islands (Melville, Byam Martin, Bathurst, &c.) on the N., Prince of Wales Land on the S. E., Prince Albert Land on the S. W., and Banks's Land or Banks's Land on the W.; length E. and W. about 200 m.; breadth N. and S. 200 m. Byam Martin channel opens into it on the N.; Banks's strait connects it with the Arctic Ocean on the N. W.; on the S. an opening discovered by Capt. Allen Young of McClintock's

expedition in 1859, and since named McClintock channel, leads between Prince Albert and Victoria Lands and Prince of Wales Land into Victoria channel; and on the E. it communicates through Barrow strait and Lancaster sound with Baffin's bay.—MELVILLE ISLAND, which lies to the N. W. of the sound, is exceedingly irregular in form, and measures about 200 m. in length from E. to W. and 180 in greatest breadth. Its coast line is broken by several deep gulfs, and it has numerous peninsulas, the chief of which are Sabine and Dundas. It is separated from Bathurst and Byam Martin islands by Byam Martin channel, and from Prince Patrick and Eglinton islands by Fitz James and Kellet straits. The geological formation of its N. part is carboniferous limestone, and of the rest lower carboniferous sandstone with beds of coal.—MELVILLE PENINSULA is a projection of the N. coast of the American continent, bounded N. by Fury and Hecla strait, which separates it from Cockburn island, E. by Fox channel, S. by Frozen strait and Rowe's Welcome, and W. by Committee bay, at the foot of the gulf of Boothia. It is connected with the mainland by Rae's isthmus at the S. W. It lies between lat. $66^{\circ} 10'$ and $69^{\circ} 50'$ N. and long. 81° and 87° W., and measures about 250 m. from N. to S. and 150 m. from E. to W.

MEMBRANE, a general term applied to thin layers of tissue, more or less elastic, of a whitish or reddish color, lining either closed cavities or canals opening externally, absorbing or secreting fluids, and enveloping various organs. The simple membranes are either mucous, serous, or fibrous, which may be briefly treated of here.—The mucous membranes are so called from the peculiar fluid or mucus which they secrete; they line the passages of the body which communicate externally, and by which foreign substances are taken in or the secretions and excrementitious matter carried off; they are continuous with the skin, perform many of its offices internally, and at the points of contact, as in the lips, can hardly be separated by a distinct demarcation. Soft and velvety, reddish and very vascular, attached to muscle, cartilage, or even peritoneum, their free surface is lined with epithelial cells, which are separated from the vascular surface by the thin, homogeneous, and apparently textureless primary or basement membrane; they present papillae upon the tongue, villousities and folds in the alimentary canal, and depressions for glands almost everywhere. The three divisions of the mucous membranes are those lining the digestive, respiratory, and genito-urinary passages. The digestive mucous membrane begins in the mouth, extends through the oesophagus to the stomach, and through the intestinal canal to the anus, sending prolongations into the ducts of the salivary glands, liver, pancreas, and gall bladder. The respiratory mucous membrane lines the nose and the cavities and sinuses connected therewith, the larynx, internal ear, larynx, trachea, and the bronchial ramifications. The genito-urinary mucous membrane extends externally from the

uriniferous tubes of the kidney, and into and through the reproductive organs. In each of these tracts the membranes present some slight modifications adapted for special functions. Mucous membranes are generally endowed with keen sensibility at their points of origin from the skin, as on the lids, lips, &c., but gradually become less sensitive and finally almost insensible, in a healthy state, in the interior of the organs; beside being the seat of various secretions and absorptions, they assist in the functions of digestion, respiration, and reproduction. (See EPITHELIUM, GLAND, and INTESTINE.)—Serous membranes are formed of fibro-cellular tissue, covered over with basement membrane and epithelial cells; they are very thin, smooth, transparent, and extensible, not having the folds, papillæ, and glands of mucous membrane; they are closed sacs, and are found wherever internal organs come in contact with each other, or lie in cavities where more or less motion is required; they consist of two layers, the first surrounding the organ itself, and the second reflected upon the parts with which it is in contact and on which it moves; the cavity is lubricated by a serous fluid, secreted by the cells and the basement membrane. They are of two kinds: those which line the visceral cavities, as the peritoneum in the abdomen, the pleura and pericardium of the lungs and heart, and the arachnoid of the brain and spinal cord; and the synovial membranes, which line the joints, sheaths of tendons and ligaments, and bursæ interposed between muscles and points of bone over which they glide. They are all shut sacs, except where the Fallopian tubes in most vertebrates open into the abdominal cavity. Serous and synovial membranes by their polished and well-lubricated surfaces secure the free movement of contiguous organs, as in the intestines, lungs, and joints; their fluid is in health only sufficient for this purpose, but in a state of inflammation the amount is largely increased, as in the dropsical effusions of peritonitis, pleurisy, pericarditis, hydrocephalus, and synovitis; their sensibility in the normal state is nothing, but in diseased conditions may become acute, as in pleurisy and peritonitis; their vitality is different from that of the organs they surround, and may be increased or diminished without the necessary participation of the latter.—Bichat gives the name of fibrous membranes to the aponeuroses of muscles, the capsules of the joints, the sheaths of the tendons, the periosteum, dura mater of the brain, the sclerotic coat of the eye, &c.; these are never free, but are in contact with and adherent to the parts surrounding, and not moistened by secreted fluid; they are whitish, of a pearly and often shining lustre, and may form sacs, sheaths, or extended layers of thin tissue; possessing elastic fibrous tissue, insensible, they afford strength to organs, retain the muscles and tendons in place, give the shape to the limbs, favor the movements of the skin and superficial muscles, and assist the venous circulation. These

membranes are variously combined; for example, the *tunica albuginea* of the testes and the pericardium are fibro-serous, a portion of the gall bladder is sero-mucous, and the ureters and membranous part of the urethra are fibro-mucous.—Membranes, especially the serous, may be formed as the accidental products of disease, as in cysts in various parts of the body. False membranes are the results or mode of termination of acute inflammation, having for their base a plastic coagulable lymph, capable of organization; such membranes are sometimes salutary, as in certain adhesions and cicatrices; at other times they impede the action of vital organs, as the pleuritic and peritonitic adhesions; under the influence of violent or special inflammations they may endanger life by closing passages, as in the false membrane thrown out in croup. (See LYMPH.) The membranes of the foetus have been alluded to under EMBRYOLOGY, and several other membranes under the organs to which they specially belong.

MEMEL, the northernmost town of Prussia, in the district of Königsberg, situated on the Baltic sea near the Russian frontier, at the N. end of the Kurisches Haff, and at the mouth of the river Dange; pop. about 11,000. It is fortified and well built, possesses several churches, an excellent naval school, and various educational and charitable institutions. The harbor is defended by a citadel, and a considerable part of the trade between Russia and Germany passes through the town. The registered shipping consists of 90 vessels; the number of clearances in 1855 was 1,820 vessels, against 1,809 in 1854. It is the centre of the Baltic timber trade. The other principal exports are grain, linseed, hemp, flax, hides, tallow, &c., most of which are received from Russia and Poland. The imports are salt, coal, colonial produce, herrings, manufactured goods, &c.—Memel was built in the middle of the 18th century by the Teutonic knights. In the 17th century it was for some time in the possession of the Swedes, and in 1757 it was taken by the Russians. In 1806, after the battle of Jena, Frederic William III. of Prussia resided some time at Memel. In 1854 the town was nearly destroyed by fire.

MEMEL RIVER. See NIEMEN.

MEMLING, HANS. See HEMLING.

MEMMI, SIMONE, or more properly SIMONE DI MARTINO, an Italian painter, born in 1280, died in Avignon in 1345. He belongs to the Siennese school, and was one of the first to modify the severity and hardness of the Byzantine manner by imitating the softer style of Giotto. After the death of the latter in 1336 he was invited to the papal court at Avignon, where he is said to have painted the portrait of Laura de Sade, on account of which he is mentioned in two of Petrarch's sonnets. At Avignon he also executed a miniature illumination for a manuscript Virgil, once owned by Petrarch and now preserved in the Ambrosian library at Milan. Of the few pictures attributed with certainty to him, an excellent specimen representing the

finding of Christ in the temple is now in the Liverpool institution.

MEMMINGEN, a fortified town of Bavaria, in the circle of Swabia, on the Aach, 41 m. S. W. from Augsburg; pop. 7,200. Here on Oct. 13, 1805, 4,000 Austrians surrendered to the French under Soult.

MEMMINGER, CHARLES GUSTAVUS, an American lawyer and politician, born in Würtemberg, Germany, Jan. 7, 1803. At about 2 years of age he was brought by his mother to Charleston, S. C., his father having previously died. He was left an orphan soon after his arrival, and was an inmate of the orphan asylum of Charleston until 9 years of age. His talents had already attracted attention, and he was received into the family of Gov. Thomas Bennett, under whose patronage he was educated at the South Carolina college, and was graduated in 1820. He began the practice of the law in Charleston in 1825. He engaged warmly in the nullification conflict as a leader of the union party, which dwindled into a feeble minority, thus preventing his political advancement. He wrote frequently for political journals during this controversy, and was the author of "The Book of Nullification" (1832-'8), satirizing the advocates of the doctrine in biblical style. In 1836 he was elected to the legislature, and was soon after sent as commissioner of the state to the legislatures of North Carolina and Kentucky with reference to the establishment of a railway connection between the Atlantic states and the Mississippi. In the legislature, he opposed the suspension of specie payment by the banks in the pressure of 1839. He was associated with the attorney-general Bailey for the prosecution in a principal case, the defence in which was conducted by Legaré, Petigru, and King; and the result was that the banks were declared to have forfeited their charters, a sentence which was afterward provisionally remitted by the state. He also urged the adoption of the sub-treasury system, and supported by an elaborate report the measures of Mr. Calhoun. In 1848 he unsuccessfully resisted the grant of a new charter to the bank of South Carolina. For nearly 20 years he was at the head of the finance committee in the lower house of the legislature, from which he retired in 1852. He was again returned in 1854, having become particularly interested in popular education and in the reformation of the public school system. The present organization and efficiency of the schools of Charleston, and especially of the normal school, are chiefly the result of his policy, which was introduced against strong opposition. In 1859 he was appointed to represent the state as a commissioner to Virginia, with a view to securing the coöperation of the states of the South against the assaults of abolitionists, the immediate occasion of the movement being the insurrectionary attempt of John Brown at Harper's Ferry.

MEMNON, a hero of the Trojan war. He was a son of Tithonus and of Eos or Aurora. Homer in the *Odyssey* describes him as the hand-

some son of Eos who brought a force of Ethiopians to assist in the defence of Troy against the Greeks. Hesiod calls him king of the Ethiopians. He was slain by Achilles. Some writers suppose him to have been an Indian, the term Ethiopians being applied to the Indians by the Greeks. Others conjecture him to have been an Assyrian general sent from Nineveh to the aid of Troy. The Greeks in later ages confounded him with the Egyptian king Amenophis III., whose colossal statue in the neighborhood of Thebes greatly excited their wonder by its vocal powers, though it seems to have been little regarded by the Egyptians. This famous statue, the vocal Memnon as it is called, is the northernmost of two colossal sitting figures, in the approach to a temple now ruined, in the quarter of western Thebes called Memnonia by the Greeks. The height of each of these statues is 47 feet, and they rest upon pedestals about 12 feet high. On the lower part of the vocal Memnon there are 72 inscriptions in Greek and Latin, by the emperor Hadrian, the empress Sabina, and by several governors of Egypt and other travellers, official and private, testifying that they have visited the Memnon and heard his voice at sunrise. It appears from these inscriptions and from the ancient writers that this vocal phenomenon was not observed till after the Roman conquest of Egypt. The sound is said to have resembled the twanging of a harp string or the striking of brass, and it occurred at sunrise or soon after. Strabo, who visited it with Ælius Gallus, the governor of Egypt, states that he heard the sound, but could "not affirm whether it proceeded from the pedestal or from the statue itself, or even from some of those who stood near its base." He does not mention the name of Memnon, and it was not till after his time apparently that the Romans began to suppose the statue to be that of the son of Tithonus. In the lap of the statue is a stone, which, on being struck, emits a metallic sound that might still be made use of to deceive a visitor; and from its position and the fact that there is a squared space cut in the block behind, as if to admit a person who might thus lie concealed from the most careful observer in the plain below, it is supposed to have been so used. Sir Gardner Wilkinson says: "Having remarked the peculiar sound of this stone, and subsequently finding in one of the inscriptions, that a certain Ballilla had compared it to the 'striking of brass,' I posted some peasants below, and ascended myself to the lap of the statue, with a view of hearing from them the impression made by the sound. Having struck the sonorous block with a small hammer, I inquired what they heard; and their answer: 'You are striking brass,' convinced me that the sound was the same that deceived the Romans, and led Strabo to observe that it appeared to him as the effect of a slight blow. That it was a deception there can be little doubt; the fact of the emperor Hadrian hearing it thrice looks very suspicious; a natural phenomenon

would not have been so complimentary to the emperor when it sounded only once for ordinary mortals." Other investigators, however, maintain that it was impossible so clumsy an imposture should have passed without detection for centuries, while the statue was constantly exposed to the inspection of intelligent Romans, who as foreigners and conquerors in Egypt would not hesitate to detect and expose the tricks of the native priesthood. It is said that similar sounds have been produced from stones by the influence of the sun's rays; and several of the scientific men attached to Bonaparte's army in Egypt have stated that they frequently heard such a sound, always shortly after sunrise, apparently issuing from one of the roof stones of the temple of Karnak. Mr. Lane states that in a neighboring temple he heard repeatedly a sound like that of a harpstring from some stone above him. This occurred at noon, and he supposes that at this time the stone became exposed to the sun, and the sudden expansion from its warmth produced the sound.

MEMPHIS, a city and port of entry of Shelby co., Tenn., situated on the Mississippi river, just below the mouth of Wolf river, on the fourth Chickasaw bluff, 420 m. below St. Louis; pop. in 1840, 8,839; in 1855, 16,000; in 1860, about 50,000. The bluff on which it stands is about 80 feet above the highest floods, and along its front extends a fine esplanade several hundred feet wide, facing which are some of the principal warehouses. The landing place is at a sandstone ridge which projects into the river from the foot of the bluff. The city is handsomely laid out and adorned with many elegant private residences. It has 15 churches (3 Baptist, 1 Cumberland Presbyterian, 8 Episcopal, 8 Methodist, 3 Presbyterian, 1 Reformed, and 1 Roman Catholic), 8 seminaries for young ladies, several male academies, an orphan asylum, 2 medical colleges, 5 daily and 8 weekly newspapers, 7 banks, and 7 insurance offices. The public schools in 1860 numbered 1,682 pupils. Memphis is by far the most important town between St. Louis and New Orleans, and has an immense business, especially in cotton, the shipments of which in the year ending Sept. 1, 1860, amounted to about 400,000 bales. Three great railroads now enter the city, viz.: the Memphis and Charleston, the Memphis and New Orleans, and the Memphis and Ohio. Forty miles of the Memphis and Little Rock railroad are also finished, and the whole is fast approaching completion. The city contains an oil factory, a car and wagon factory, a steam boiler factory, and 8 iron foundries. It was laid out in 1820.

MEMPHIS (Egyptian, *Menfis* or *Mennofra*, "good abode" or "the abode of the good one"—Osiris; in Scripture, *Moph*), an ancient capital of Egypt, situated on the W. bank of the Nile, 10 m. S. from the modern city of Cairo, in lat. 30° 6' N., long. 81° 15' E. Herodotus gives the following account of its foundation: "The priests said that Menes was the first king of Egypt, and that it was he who raised the dike which pro-

fects Memphis from the inundations of the Nile. Before his time the river flowed entirely along the sandy range of hills which skirts Egypt on the side of Libya. He, however, by banking up the river at the bend which it forms about a hundred furlongs south of Memphis, laid the ancient channel dry, while he dug a new course for the stream half way between the two lines of hills. To this day, the elbow which the Nile forms at the point where it is forced aside into the new channel is guarded with the greatest care by the Persians and strengthened every year; for if the river were to burst out at this place and pour over the mound, there would be danger of Memphis being completely overwhelmed by the flood. Menes, having thus, by turning the river, made the tract where it used to run dry land, proceeded in the first place to build the city now called Memphis, which lies in the narrow part of Egypt; after which he further excavated a lake outside the town, to the north and west, communicating with the river, which was itself the eastern boundary. Beside these works, he also, the priests said, built the temple of Vulcan (Phthah), which stands within the city, a vast edifice, very worthy of mention." According to Diodorus, Memphis was about 17 m. in circuit. The mounds of the modern village of Mitrahenny mark the eastern portion of the city, while its western limits extended beyond the pyramids of Sakkara, and included in its suburbs those of Abousir and Dashoor. It was remarkable for its fine and healthful climate, and for the beauty of the view from its walls. Rich green meadows, covered with lotus flowers and intersected by canals, bounded it on the N. and S. Its position was such as to command the whole inland trade of Egypt, ascending or descending the Nile. It was the chief seat of learning and of religion in Egypt, the principal place of the worship of the god Phthah, and the chosen residence of the sacred bull Apis, whose temple here was celebrated for its colonnades through which the great processions were conducted. The other great temples were: that of Isis, which Herodotus describes as spacious and beautiful, commenced at a very early period, and completed by Amasis, 564 B. C.; the temple of Serapis, in the western quarter of the city; the temple of Phra or the sun; and the temple of Phthah, the most ancient of all, and the largest and most superb.—Memphis was the seat of successive dynasties, the 3d, 4th, 5th, 6th, 7th, and 8th of Egyptian history, who reigned, with one considerable interval, for nearly 1,000 years. By the 4th dynasty the great pyramids were built. It was also the capital during the supremacy of the shepherd kings. At a still later period, under the dynasties that succeeded the Theban, it became again the royal abode. The Persians made it the metropolis of their African possessions, and it continued to be the chief city of Egypt until the foundation of Alexandria, after which it gradually declined, and in the course of ages sunk into such utter

decay that its very site, overwhelmed with drifted sand, was a matter of dispute among antiquaries. The researches of M. Mariette since 1850 have removed all doubt as to its position, and have disclosed an immense amount of remains, including ruins of temples and of palaces, and statues, bass-reliefs, and inscriptions, to the number of several thousand.

MÉNAGE, GILLES, a French author, born in Angers, Aug. 15, 1618, died in Paris in 1692. He studied law and practised for a short time in Angers, Paris, and Poitiers, but abandoned this profession for the church. He lived for a short time with Cardinal de Retz, but finally established himself in a house in the cloister of Notre Dame, where on Wednesdays he entertained numbers of the wits and scholars of his day. His wit and erudition became celebrated, and the *mercuriales*, as the meetings at his house were called, are still mentioned by scholars. The quarrels of Ménage, his social relations, and the epigrams and witticisms which they called forth, occupy a prominent position in the literary history of the 17th century. He wrote many works, of which the most important are: *Origines de la langue Française* (Paris, 1650), afterward enlarged and published as *Dictionnaire étymologique de la langue Française* (1694); *Poemata Latina, Gallica, Græca et Italica* (1658); and *Anti-Baillet* (1685). After his death, his friends published, under the title of *Ménagiana*, a collection of his witticisms and table talk, which was highly praised by Bayle. The best edition is that by La Monnoye (1715).

MENAI STRAIT, a narrow channel of Wales, which separates the island of Anglesea from Caernarvonshire. Its direction is nearly S. W. and N. E., its length about 11 m., and its breadth from 200 yards to 2 m. The navigation of this strait was formerly very difficult and hazardous; but, in consequence of the removal of many of the rocks which obstructed it, vessels of less than 100 tons burden, and sometimes larger craft, can now pass through in safety. The Menai channel is crossed by two stupendous bridges about a mile apart, the Menai suspension bridge and the Britannia bridge, for an account of which see BRIDGE, vol. iii. pp. 689, 690.

MENANDER, an Athenian dramatic poet, born in 342, died in 291 B. C. Alexis, the comic poet, was his paternal uncle, Theophrastus his preceptor, and Epicurus his intimate friend. Few of the events of his life are known. The merits of his comedies gained him the patronage of Demetrius Phalereus, and of the first Ptolemy, who invited him to his court at Alexandria; this invitation he however declined. His intimacy with Phalereus involved him in danger after the expulsion of that statesman from Athens by Poliorcetes; and he would have been put to death had it not been for the intercession of Telesphorus, son-in-law of the latter. He is said to have been drowned while swimming in the harbor of Piræna. The Athenians raised a monument to his memory beside that of Euripides,

and placed his statue in the theatre. Menander was the greatest poet of what is termed "the new comedy." He it was in fact who purified it from the coarseness and buffoonery of the old comedy, and infused into it that pathos and elevation of sentiment which distinguished it from the productions of Aristophanes, his great predecessor in the comic drama. He was the author of a vast number of comedies, which maintained their place on the stage for some centuries, and were models for both Greeks and Romans. Of his imitators Terence was the most servile and unscrupulous, his plays being almost entirely translations or aggregations of those of his Hellenic master. Hence Cæsar's celebrated sarcasm relative to the plagiarist: *O dimidiato Menander*. The *editio princeps* of the extant fragments of Menander is that of Morellius (Paris, 1553); the best edition is that of Meineke in his *Fragmenta Comicorum Græcorum* (Berlin, 1841). See BENOÎT, *Essai historique et littéraire sur la comédie de Ménandre* (Paris, 1854).

MENARD, a central co. of Ill., bounded N. partly by the Sangamon river, which intersects it; area, 802 sq. m.; pop. in 1855, 8,029. It has a level surface and productive soil. The productions in 1850 were 69,106 bushels of wheat, 1,280,206 of Indian corn, 129,107 of oats, and 81,752 lbs. of wool. There were 11 grist mills, 11 saw mills, 2 woollen factories, 8 tanneries, 13 churches, and 720 pupils attending public schools. Capital, Petersburg.

MENASSEH BEN ISRAEL, a Dutch rabbi, born in Spain about 1604, died in Amsterdam about 1659. His father, a concealed Jew, fled to Holland, and settled at Amsterdam, where the son was placed under the tuition of Rabbi Isaac Uziel. At the age of 18 he succeeded his master in the office of preacher and expounder of the Talmud. He established a press in his own house, at which he printed 3 editions of the Bible, and several rabbinical books in the Hebrew and Spanish languages. During the protectorate he visited England, and was graciously received by Cromwell, for whom he wrote his "Defence of the Jews" (London, 1656), soliciting for that people the permission to settle in England, whence they had been expelled since the reign of Edward I., which was granted. He was the author of many learned theological works in various languages, the most important of which are: *Conciliador nel Pentateucho* (Amsterdam, 1682), translated into Latin by Dionysius Vossius; *De Resurrectione Mortuorum* (1686); *De Fragilitate Humana ex Lapso Adami, deque Divino Auxilio* (1642); and *Spee Israelis* (1650). His "Defence of the Jews" was translated into German by the philosopher Mendelssohn, and augmented by an equally valuable introduction. An English version of the *Conciliador* was published in London in 1842 (2 vols. 8vo.). His life has been written in English by the Rev. Thomas Pococke (London, 1709).

MENDÆANS. See CHRISTIANS OF ST. JOHN.

MENDELSSOHN, Moses, a German scholar and philosopher of Jewish race, born in Dessau, Sept. 10, 1729, died Jan. 4, 1786. His father was a transcriber of the Pentateuch and master of a Hebrew day school, both precarious professions. He was early sent to the public Talmud school, where he was taught to recite mechanically the Mishna and Gemara, and relates that at the age of 7 years he was usually called up at 8 or 4 o'clock in the morning to proceed to the severe tasks of the school, after drinking a cup of tea. Even at that age he manifested a spirit of thorough inquiry, and mastered the Hebrew language, so that he could write it with purity and elegance, and also metrically. He was still young when the "Guide of the Erring" (*Moreh nebukhim*), by Maimonides, became the object of his enthusiastic study. He meditated on it by day and by night, acknowledged throughout his life his obligations to it, and by his severe study of it, regardless of health, laid the foundation at once of his mental culture and of bodily disease and suffering. "Maimonides," he wrote, "is the cause of my deformity; he spoiled my figure, and ruined my constitution; but still I doat on him for the many hours of dejection which he has converted into rapture." At the age of 14 he followed his friend and teacher Rabbi Frenkel to Berlin, and, without the means of procuring a single meal, was eager only for erudition. His engaging manners, notwithstanding his extreme diffidence, gained him friends; and having been presented by a patron of aspiring young Jews with an attic lodging room and two days' board weekly, he began to prosecute his studies of the Talmud and of philosophy. He had long meditated how to learn the Greek and Latin languages without oral instructions or even an elementary book, when a young physician noticed his enthusiasm and offered him a quarter of an hour daily of gratuitous instruction. Having overcome the declensions and verbs, and purchased a second-hand dictionary with a few groschen which he had earned by copying, he was prepared to read whatever Latin book he could get hold of. This happened to be a Latin translation of Locke's "Essay on the Human Understanding;" and so thoroughly did he make his way through philological and metaphysical difficulties, that on completing the task he was able to read the Latin classics with ease and judgment. He became intimate with the mathematician Israel Moses, under whom he studied Euclid in a Hebrew translation, and with whom he discussed what he read in Latin and German. Through another friend he obtained elementary instruction in the French and English languages. It had been his custom whenever he purchased a loaf to notch it according to his pecuniary prospects into so many meals, never eating according to his appetite, but to his finances. At length he became acquainted with an opulent Jewish manufacturer, and was admitted into his family at first as tutor to his children, but subsequent-

ly became his partner in business. By day he managed an extensive silk manufactory, while the greater part of his nights was devoted to study and writing. In 1744 began his acquaintance with Lessing, and the latter pages of the *Morgenstunden* record their enduring mutual affection. Their recognized intimacy, and the accession of Nicolai and Abbt to the circle, contributed much to overthrow the *Judeophobia*, then a prevalent prejudice in Germany. He had previously published some moral tracts, in illustration of aphorisms extracted from rabbinical writings. In 1755 he published a treatise *Ueber die Empfindungen*, a profound disquisition on problems of aesthetics, and in connection with Lessing a discussion entitled *Pope ein Metaphysiker*, the design of which was to elucidate the maxim: "Whatever is, is right." These were followed by other short treatises remarkable for their acuteness, originality, ethical tone, and beauty of style, which, after passing through several editions separately, were collected under the title of *Philosophische Schriften* (Berlin, 1761). He was one of the most active contributors to the *Bibliothek der schönen Wissenschaften*, and to the *Briefe, die neueste Literatur betreffend*. The royal academy of Berlin awarded him the prize for a memoir on the question: "Are metaphysics susceptible of mathematical demonstration?" though Kant was one of his competitors. In 1762 he was married, and the death of his first child in the following year was the occasion of his defending Spalding against Abbt in their controversy on human destiny. His interest in the subject led him to write an imitation of Plato's "Phædon," adding all the proofs of the immortality of the soul that could be collected or suggested, and thus producing his most popular work, entitled *Phædon, oder über die Unsterblichkeit der Seele* (Berlin, 1767), which was soon translated into almost all European languages, as well as into Hebrew. His leading and peculiar argument is that for every change there must be an intermediate condition between the first and the second state, a period of time in which the process of change takes place; that the soul, being simple, and incapable of resolution into component parts, can perish only by being absolutely annihilated; that there can be no intermediate state between life and annihilation, being and not-being; and that therefore, the necessary conditions not being satisfied, the change cannot be operated, and the soul is immortal. Kant has shown the failure of this argument against the hypothesis of gradual annihilation. We can conceive that the soul may be gradually extinguished, without any resolution of parts; that its "intensive magnitude," as Kant terms it, may be gradually diminished, as a deep blue color may gradually fade away without any diminution of the colored surface. Mendelssohn's fame was at its height, and the learned were wondering that so elegant and philosophic a scholar should be at once so strict a Hebrew and so liberal in his

expressions, when he received a public challenge from Lavater either to refute Bonnet's arguments in support of Christianity or to renounce Judaism. Constitutionally averse to all controversy, and habitually reserved on subjects of religious dispute, he answered the challenge with an adroitness and candor that satisfied all parties, and while avoiding either horn of the dilemma drew from Lavater an apology and retraction of his peremptory address. The agitation caused by this matter induced a dangerous illness, which for a long time rendered him incapable of intellectual labor. Mendelssohn exerted an important influence by his efforts for the elevation of his Jewish countrymen. His German translation of the Pentateuch, and metrical version of the Psalms, are admirable for elegance and perspicuity; and their publication, accompanied by scriptural comments in Hebrew by himself and a circle of friends, makes an epoch in the history of modern Judaism. In defence of the rights of his Jewish brethren he wrote his introduction to his translation of Rabbi Menasseh ben Israel's "Apology of the Jews" (Berlin, 1782). In 1783 appeared his *Jerusalem, oder über religiöse Macht und Judenthum*, a vindication both of religious tolerance and of Judaism, and still one of the best books on those topics. He published in 1785 his *Morgenstunden*, consisting of lectures on the existence of God, the original design of which had been to instruct his eldest son and other Jewish youths in the principles of religion. It contains an affectionate memorial of Lessing, and was the occasion of Jacobi's letters to him *Ueber die Lehre des Spinoza*, in which Lessing is charged with being a Spinozist. Mendelssohn immediately answered with his usual sagacity, and with unusual indignation and irony, in a dissertation addressed *An die Freunde Lessings*, concerning which Kant said: "It is Mendelssohn's fault that Jacobi thinks himself a philosopher." His health was seriously injured by the excitement attending this effort, and a slight cold caught soon after terminated fatally. No other German author has given to philosophical thought so simple and noble an expression in the form of epistles and dialogues.—The most complete edition of his works appeared under the care of his grandson G. B. Mendelssohn (7 vols., Leipsic, 1843-'5). His life was written, among others, by Samuels (2d ed., London, 1822).

MENDELSSOHN-BARTHOLDY, FELIX, a German musical composer, born in Hamburg, Feb. 3, 1809, died in Leipsic, Nov. 4, 1847. He was a grandson of Moses Mendelssohn, and many of his other relatives were distinguished persons. His father, Abraham Mendelssohn-Bartholdy, founded in connection with his brother Joseph the firm of Mendelssohn and co., still continued by the brothers of Felix as one of the first banking houses of Europe. His father had added the name of Bartholdy to his own, out of regard for his wife, a lady of the Bartholdy family, which had also produced sev-

eral eminent persons, and most members of which have exchanged the Jewish for the Christian faith. The father of Felix, too, became a convert to Christianity, and the son was brought up in the Lutheran faith in Hamburg, whither his parents had removed during his infancy. Goethe was foremost among the many distinguished persons who became interested in his precocious genius, and Hummel predicted for him a brilliant career. Indeed, he could almost sing and compose before he could speak, and he was not yet 6 years old when he displayed his skill on the piano. Zelter, the friend of Goethe and the teacher of Meyerbeer, became his instructor in composition, and Ludwig Berger his master on the piano. In his 9th year he gave his first public concert in Berlin, and a year afterward in Paris. From that early age he began to write compositions for the piano, violin, viola, and violoncello; and 3 of his quartets published in 1824 still hold a place among classical musical works. In 1825 he made a second journey to Paris with his father, who was at length determined by the encouraging advice of Cherubini and other competent judges to let his son devote himself exclusively to music as a profession. He gave successful concerts in Paris in company with Baillot, and after his return to Berlin produced in 1827 his first opera, *Die Hochzeit des Gamacho*, in which the principal characters of Cervantes's "Don Quixote" are introduced. But the music met with a cold reception, and the opera was immediately withdrawn from the stage. He now travelled several years in England, France, and Italy, and was rewarded for his unremitting zeal by the unbounded admiration with which his overture to Shakespeare's "Midsummer Night's Dream" was universally received. In this composition the influence of the genius of Weber upon his mind is especially evident in the ideas and the coloring; but although the artistic construction is irreproachable, the overture, as a whole, is deficient in the originality of that master's fairy work and supernaturalism. But the fanciful, the delicate, and the grotesque are deliciously blended in the music, which breathes throughout Shakespeare's own inspiration. Mr. Benedict says of it: "The effect of the first performance of the overture in London was electrical. All at once, and even when least expected, the great gap left by the death of Beethoven seemed likely to be filled up." The rest of the music for the "Midsummer Night's Dream" was written by him afterward for the purpose of accompanying the performance of the play. Mendelssohn spent some time in Edinburgh, and immortalized the popular music of the Scotch bagpipers by his symphony in A minor, since called the Scottish symphony, which was first performed under his own direction by the London philharmonic society. Many other reminiscences of his tour through the highlands are to be found in his compositions and his orchestral pieces. "The Isles of Fingal" reproduces the impressions

which the wild shores of the Hebrides had made upon him. After his return to Germany he endeavored to establish, in concert with Immermann, musical and dramatic entertainments at Düsseldorf, to consist solely of the most select productions. This enterprise failed, but increased his reputation as a conscientious artist, ambitious to impart to his profession the highest character of excellence. His residence at Berlin was embittered by the intrigues of his opponents, and in 1835 he accepted the directorship of the famous Leipsic concerts, which under his care attained to an unprecedented degree of perfection. He was, however, even more appreciated in England than in his own country, and chiefly on account of his compositions of sacred music. His oratorio "St. Paul," after having been produced at Düsseldorf and Leipsic, was performed under his own direction at the Birmingham festival of Sept. 20, 1837, where it was received with great enthusiasm. His fame rests in a great measure upon this oratorio and upon that of "Elijah," which was written expressly for the Birmingham festival, the first performance taking place there Aug. 26, 1846. It is considered in England as his crowning work. Mendelssohn had been engaged for 9 years upon this composition, and had resigned the post of inspector of music, which he had for some time filled in Berlin, in order to superintend its performance in England; and shortly before his death he was again in London to attend personally the sacred harmonic society's concert at Exeter hall. He had resumed his place at Leipsic since 1845; and shortly after his return there from his visit to England in 1847, his health was impaired by grief at the sudden death of a beloved sister. A tour to Switzerland for the recovery of his strength brought only temporary relief; a relapse took place soon after his return to Leipsic, and he died in the prime of his manhood from an affection of the brain. Of his many posthumous compositions none have yet been published excepting a fragment of an oratorio entitled "Christus," and some scenes of "Loreley," a romantic opera; but they are understood to include many other important compositions. Among the most famous of his many published works are his music for Goethe's "Walpur-gis Night," the "Antigone" and "Œdipus" of Sophocles, "Athalie," and a great number of admirable sonatas, concertos, trios, &c. In his "Songs without Words" for the pianoforte, Mendelssohn opened a new vein of beauty, and produced an indispensable work for pianists by throwing aside language and indulging in supposititious sentiment, at the same time keeping in view the scope and character of the instrument, and inventing charming traits of accompaniment. Mendelssohn's appreciation of dramatic effect, so remarkably displayed in his music to the "Midsummer Night's Dream," led his friends to expect from him important contributions to the lyrical drama; but his admiration for Bach and Handel led him to the comparatively easier labor of composing sacred

music. England especially, with her great school for the oratorio at Exeter hall, and with her resources of choral singing and the religious sentiment of the people in favor of sacred music, proved auspicious for the great works of Mendelssohn. In devoting himself to the oratorio, this master had the tact not to stifle it with fugues, but to write dramatically, and with freedom from antiquated formalisms. His oratorios have thus become the pillars of his fame. Mendelssohn was as much beloved for the beauty of his character as for his genius. His life was free from the struggles and cares which generally beset aspirants for renown, and from his earliest childhood he was permitted to indulge his tastes without hindrance. He devoted himself exclusively to his profession, and brought to bear upon it the severe studies of a laborious artist and the equanimity of a serene and dispassionate mind. He lacked the fire and the spontaneity of the poetic nature, but he was deeply penetrated with a sense of the dignity and value of his mission. His works form a noble page in the progress of music in the 19th century.

MENDES, a city of ancient Egypt, situated in the delta at the point where the Mendesian arm of the Nile flows into the lake of Tasis. It was a considerable place under the Pharaohs, but was in ruins in the 1st century B. C. Its remains are seen in the mounds of Ashmoun on the canal leading to Menzaleh. It was the seat of the worship of a deity represented under the form of a goat, whom the Greek writers on Egypt called Pan, but who was probably Khem, one of the 8 great gods of Egypt, and the symbol of the generative principle.

MENDEZ-PINTO, FERNAM, a Portuguese adventurer, born at Old Montemayor, near Coimbra, about 1510, died at Almada, near Lisbon, about 1580. He was the child of poor parents, and in 1521 was placed in the service of a noble lady of Lisbon. At the end of a year and a half an adventure, the particulars of which are not known, put his life in peril, and caused him to embark precipitately on a ship just going to sea. The vessel was soon taken by pirates, who after much ill treatment put him ashore on the coast of Portugal. Afterward he passed into the service successively of two noblemen, and at length, in search of fortune, sailed for the East Indies, and in 1537 arrived at Diu on the W. coast of Hindustan, which city the Portuguese had seized and fortified two years before. Here he embarked as a volunteer in a vessel sent to cruise against the Turks in the Indian ocean and Red sea. After various adventures and a visit to Abyssinia, Pinto was captured by the Turks near Bahair mandeb, carried to Mocha, and sold as a slave first to a Greek renegade, and next to a Jew, from whom he was ransomed by the Portuguese governor of Ormus, who furnished him with the means of returning to India. At Goa he met Dom Pedro de Faria, captain-general of Malacca, who, perceiving his ability, took him

into his service and sent him on numerous missions to the native princes. On one of these expeditions he was shipwrecked, made a slave, and sold to a Mohammedan merchant who carried him to Malacca for ransom. He was soon sent on another mission to the gulf of Siam; but his vessel, while lying in the river near Lugor, was boarded and captured by pirates. He escaped, though wounded, by swimming to the shore, and having reached Patana, a Portuguese port south of Lugor, he engaged with some friends in fitting out a small cruiser and went in search of the pirates, several of whose vessels richly laden the Portuguese captured, though they soon lost by shipwreck all the treasures thus acquired. Pinto and his companions then procured still another vessel, met and captured the pirate who had robbed them at Lugor, suffered another shipwreck, and some of them having been detained as prisoners at a town on the coast of China, the others rescued them and plundered the place, and then put into Liampo, or Ningpo as it is now called. Here Pinto and some other Portuguese, in May, 1542, were persuaded by a Chinese pirate to undertake an expedition to the island of Calempui, not far from Peking, where, as they were led to believe, were the tombs of 17 Chinese kings, containing vast treasures. Their attempt to plunder these tombs was only partially successful, and they fled terrified at the alarm raised by the guardians of the treasures. Shortly afterward they were again shipwrecked on the Chinese coast; and after witnessing the drowning of most of his comrades, Pinto with a few others got on shore, where they lived awhile by begging, but were apprehended and taken to Nanking, and on a charge of being thieves were condemned to lose their thumbs; but by appealing, they got this punishment commuted into imprisonment in the town of Quansi on the northern frontier, where they were set to work in repairing the great wall. They were delivered in a few months by an inroad of Tartars, who carried them to assist in the siege of Peking, and then took them back to Tartary. After a short residence in that country Pinto went in the train of an ambassador to Cochin China, and from there made his way to Macao, which was not yet occupied by the Portuguese. Here, in default of any other resource, he enlisted with two other Portuguese in the service of a Chinese pirate, whose vessel, after a desperate engagement with a superior force of other pirates, escaped under cover of the night and was driven by a gale to the coast of Japan, which had not then been visited by Europeans. Pinto was well received by the Japanese, and after a considerable stay in their country he sailed back to Liampo with the Chinese pirate. His report of the discovery of Japan and its great wealth and magnificence created such an excitement among the Portuguese at Liampo, that in 15 days 9 hastily equipped ships were despatched for the new Eldorado. Eight of them foundered on the voyage, and the one in

which Pinto sailed was driven to the Loo Choo islands, then first seen by Europeans, and wrecked there. Pinto with difficulty got ashore, and after many fresh adventures and dangers found his way back in a Chinese junk to Liampo, whence after still more vicissitudes he proceeded to Malacca. He next visited Pegu, Siam, Java, and some of the neighboring countries, in which he met with a singular variety of fortune; and in 1547 he embarked at Malacca on a second voyage to Japan. Soon after his arrival there a civil war broke out, in which Pinto took part for a while; but having at length profitably disposed of the merchandise he carried thither, he returned to Malacca, where he met St. Francis Xavier, "the apostle of the Indies," with whom in the course of a few months he made a third visit to Japan, arriving there in Aug. 1548. By these voyages to Japan Pinto acquired great wealth, and in 1553 he was at Goa, preparing to return to Portugal, when the arrival there of the body of Xavier, and his conferences with Father Nugnes Barreto, the vice-provincial of the Jesuits, so excited his religious enthusiasm, that he devoted his whole fortune, except 2,000 crowns which he sent to his poor relations in Portugal, to the foundation of a seminary for propagating the faith in Japan. He was then appointed ambassador from the Portuguese viceroy of India to the king of Bungo in Japan, and sailed for that country in company with the Jesuit Nugnes. Before setting out he took the vows as a member of the order of Jesuits; but on his arrival in Japan his zeal evaporated, and he was released from his vows. He returned with Nugnes to Goa, and sailed thence for Lisbon, where he arrived Sept. 22, 1558, bearing to the queen regent a letter from the viceroy at Goa, recommending him warmly to the favor of the government as a man of the highest experience in East Indian affairs. He spent a few years in attendance on the court, which brought him nothing but promises, and which he says were more tedious and harassing than his 21 years of service in the East, though during that time he had been 18 times taken by the enemy and 17 times sold as a slave. The first extant account of his travels and adventures is given in a collection of Jesuits' letters published in Italian at Venice in 1565. He wrote a full narrative of his life, which was published long after his death by Francisco de Andrada under the title of *Peregrinação de Fernam Mendez-Pinto* (4to., Lisbon, 1614). Few books have been more popular. In Portugal editions were printed in 1678, 1711, 1725, and 1762. A Spanish translation by Francisco de Herrera, in which great liberties were taken with the original, appeared in 1620; a French translation was made by Bernard Figuier, of which 8 editions have been printed (Paris, 1628, 1645, and 1880), and an English translation by H. Cogan, of which there have been two editions (London, 1668 and 1692). Pinto's reputation in English literature has suffered greatly by an oft quoted line in Con-

greve's "Love for Love:" "Ferdinand Mendez-Pinto was but a type of thee, thou liar of the first magnitude!" But it is now admitted by critics and scholars that his general veracity cannot be disputed. The countries in which his adventures happened are still many of them little known, but the more they have been explored the more has the correctness of his statements become apparent. Rémusat, the eminent Chinese scholar, cites him as good authority for facts, and Malte-Brun remarks that in writing about eastern Asia he had carefully examined Pinto's work, and was strongly confirmed in his opinion of the reality of his adventures and the general correctness of his memory.

MENDICANTS, or **BEGGING FRIARS**, a class of monastic orders in the Roman Catholic church, the members of which were originally bound to have no property of their own, but to look for their support to the charitable contributions of the people. The first Mendicants were the Franciscans, established in 1210, and the Dominicans, established in 1216; but later several other orders were declared by the pope to be Mendicants, as the Carmelites in 1245, the Augustinian Hermits in 1256, and the Servites.

MENDIZABAL, JUAN ALVAREZ Y, a Spanish financier, born in Cadiz about 1790, died in Madrid, Nov. 8, 1853. He was the son of a small Jewish trader named Mendez, and by his business tact succeeded in 1808 in obtaining an employment in the victualling department of the French army in Spain. After the war he was for some time attached to a banking establishment in Madrid. In 1819 he procured funds for the revolutionary army, and after the reestablishment of the constitutional government he assisted the finance minister Arguelles in the negotiation of loans. On the downfall of that government he fled to England, where he was for some time imprisoned at the instance of some English capitalists whom he had induced to take parts of the loan. After the recovery of his liberty he founded, with the aid of funds deposited with him by a friend, a commercial establishment, which became prosperous. On occasion of some journeys to Portugal he formed the acquaintance of an agent of Dom Pedro, and succeeded in negotiating a loan for him in London. This and other operations secured for him an extensive reputation both in England and Spain, which in June, 1835, led to his appointment as minister of finance in the cabinet of Toreño; but he continued to reside for some time in London, where in August he negotiated a loan of £1,150,000 for the Spanish government. On his return to Madrid he was received with great favor, and his success in financial matters became a stepping-stone to political influence. He boasted of his ability to restore tranquillity in Spain within 6 months; he was appointed president of the council in place of Toreño; the cortes placed 100,000 men at his disposal, and gave him full authority to act to the best of his judgment in bringing the civil war to a close. But he injured the credit of the govern-

ment by jobbing transactions with the house of Ardoni, increased the public debt, dissolved the cortes (Jan. 27, 1836), insulted the French ambassador, Count de Rayneval, who opposed his influence, and failing in restoring order within the stipulated time, he was compelled to resign (May 15). His reappointment as minister of finance (Sept. 11, 1836) gave rise to great indignation, and on Aug. 10, 1837, he withdrew from office, together with the other members of Calatrava's administration. For several years afterward he sat in the cortes as a member for the province of Madrid. In 1841, under Espartero, he was again minister of finance, but his devotion to that leader compelled him to share his fate in July, 1843. He first fled to Portugal, and afterward to England, eventually taking up his residence in Paris, where his wealth enabled him to live in great splendor. In 1848 he was permitted to return to Madrid.

MENDOZA, a province of the Argentine confederation, extending along the E. declivity of the Andes from lat. 32° to 34° 38' S., bounded N. by the province of San Juan, E. by San Luis, S. by Buenos Ayres, and W. by the republic of Chili; pop. in 1855, 40,000. It is nearly of quadrangular form, being about 150 miles in length and breadth. The districts immediately bordering on the Andes are mountainous, and contain several volcanoes; but the greater part of the surface is level. The chief rivers are the Desaguadero, Mendoza, and Tunuyan. The climate is dry and healthful, though warm in summer. The soil, though in general sandy and barren, yields when irrigated abundant crops of wheat, maize, barley, fruit, and lucern. The most important mineral productions are silver, copper, slate, gypsum, alum, and medicinal salts. At Uspallata are mines of the first named metal which were formerly very profitable. The state is ruled by a governor elected by its legislature.—**MENDOZA**, the capital, is situated at the base of the Andes, 2,891 feet above the level of the Atlantic, in lat. 32° 53' S., long. 69° 6' W.; pop. from 10,000 to 12,000. It is a pleasant city, and noted for its salubrity. The houses are generally adorned with porticoes, and surrounded with gardens. The alameda, or public promenade, is nearly a mile in length, and sheltered throughout by rows of stately poplars. The principal buildings are the churches and convents. In the vicinity are numerous well cultivated vineyards.

MENDOZA, DIEGO HURTADO DE, a Spanish scholar, author, and statesman, born in Granada in 1503, died in Valladolid in 1575. Lope de Vega mentions that in his time the name of Mendoza had been "nobly great" for 23 generations, and the family sometimes claimed descent from the Cid himself. The 8 immediate ancestors of Diego were successively distinguished as the poet and wit of the court of John II., the ambassador of Ferdinand and Isabella to the see of Rome, and a Spanish general against the Moors, who became governor of Granada after its surrender. Diego was originally destined for

the church, and was educated in Latin, Greek, and canon and civil law at the university of Salamanca. There he wrote his *Lazarillo de Tormes* (Antwerp, 1553), which proves that he was interested rather in fictitious literature than in theology. It is a satirical romance, and became the foundation for the whole class of Spanish fictions in the *gusto picaresco*, which the *Gil Blas* of Le Sage subsequently made famous throughout Europe. The leading character is a dexterous rogue, who in the capacity of a servant sees the actors in all grades of society behind the scenes. The work was often reprinted, and provoked many imitations. After leaving the university, instead of entering the church, he served as a soldier in the Spanish armies in Italy, and when the troops were unoccupied listened to the lectures of the professors at Bologna, Padua, and Rome. In 1588 Charles V. sent him as ambassador to the republic of Venice, where Paulus Manutius dedicated to him an edition of the philosophical works of Cicero, and where he exerted himself for the collection of Greek manuscripts. He afterward became military governor of Sienna, and somewhat later was sent to maintain the imperial interests in the council of Trent, from which he was withdrawn in 1547 to proceed as a special plenipotentiary to Rome to confront and overawe Pope Julius III. For 6 years he was regarded as the head of the imperial party throughout Italy. He returned to Spain when the emperor changed his policy before abdication, and under Philip II. was not in favor and seldom went to court. In a passionate dispute with a courtier in the palace, the latter drew a dagger, when Mendoza wrested it from him, and threw it, and according to some accounts the courtier also, out of the window. He was in consequence banished from court, and solaced his exile by writing poetry and history. His poems display the old Castilian national tone of feeling and reflection, modified by his familiarity with the classical and Italian poets. His epistle to Boscan and hymn to Espinosa are equally marked by his Spanish genius and classical studies. A gayety worthy of the author of the *Lazarillo* appears in some of his *letrillas*. There is but one edition of his poems (Madrid, 4to., 1610), a rare and valuable book. His principal historical work is the *Guerra contra los Moriscos* (1568-70), a record of the Moorish insurrection. It is esteemed one of the finest specimens of historical writing in the Spanish language, is in a picturesque and energetic style modelled after that of Sallust, and, notwithstanding his Spanish sympathies, is so impartial with respect to the enemies of his faith and people that it could not be published till long after his own death, the first complete edition being that of Monfort (Valencia, 1776). This was his last literary labor, and on finishing it he presented the whole of his library, including classics, manuscripts, and curious Arabic works, to the king for the palace of the Escorial. His life by Antonio is contained in the *Biblioteca Nueva*.

MENDOZA, INIGO LOPEZ DE. See SANTILANA.

MENELAUS, one of the Homeric heroes, the son of Atreus and younger brother of Agamemnon, and king of Lacedæmon. After his wife, the beautiful but faithless Helen, had eloped with Paris, he and Ulysses proceeded to Troy to demand her restitution. In the war which followed the refusal he repeatedly distinguished himself, slaying many Trojans in single combat. He also engaged Paris, and would have killed him had not Venus interfered and enabled her favorite to escape. Menelaus was also one of the warriors concealed in the wooden horse, whose introduction into the city led to its capture and destruction. On recovering Helen he embarked for home; but when he arrived off the Maleian coast Jupiter sent a storm which scattered his fleet, and drove the ship that bore him and Helen as far as Egypt. With the exception of Ulysses, he was the last of the Hellenic heroes that reached Greece. His latter days were passed in peace and prosperity. He was the father of several children by Helen.

MENES. See EGYPT, vol. vii. p. 36.

MENGES, ANTON RAFAEL, a German painter and writer on art, born in Aussig, Bohemia, March 12, 1728, died in Rome, June 29, 1779. His father, a miniature painter of very moderate ability, having determined to make an artist of him, took him when a child to Dresden, and compelled him to pursue his art studies without relaxation. Young Menges, however, thrived so well under this severe treatment, that in his 8th year he designed a subject from the *Æneid*, and at 14 was a skilful painter. In 1741 his father took him to Rome, and compelled him to devote nearly his whole time, with the exception of the few hours given to sleep, to the study of the works of Raphael and the old masters in the Vatican, of which he made several copies in miniature for Augustus III. of Poland and Saxony. Returning to Dresden at the end of 3 years, he was appointed court painter to Augustus, with permission to return to Rome. During his second visit to that city he established his reputation by a holy family, the figure of the Virgin in which was painted from a beautiful peasant girl, whom he subsequently married. In 1749 he was compelled by his father to return to Dresden, but during the next few years the tyranny of his parent became so intolerable that his health and spirits suffered, and he obtained the permission of the elector to return to Rome. His talents began to be developed rapidly, and among the works which he executed in the next few years were a copy of Raphael's "School of Athens" for Lord Percy, afterward duke of Northumberland, the frescoes in the church of San Eusebio, and those of "Apollo and the Muses on Parnassus" in the Villa Albani, which have been engraved by Raphael Morghen. About this time he attracted the notice of the king of Naples, who, upon succeeding to the throne of Spain as Charles III., invited him in 1761 to Madrid. He executed a number of

works in the royal palace of that city, including his "Anrora;" but was finally compelled by ill health to return to Rome. On a second visit to Spain he painted in the grand saloon of the palace at Madrid his fresco of the "Apotheosis of the Emperor Trajan." Failing health, caused by unremitting devotion to his art, compelled him again to resort to the more genial climate of Italy. Stopping at Monaco on his way to recruit, he painted there his picture of the "Nativity." The king valued this work so highly that he caused it to be covered for protection by a glass plate 9 feet 10 inches by 7 in dimension. He died soon after his arrival in Rome of despondency at the loss of his wife. His merits have been much exaggerated by his friends, particularly Winckelmann, who ranked him higher than Raphael, and quite as much underrated by others. As a theorist and writer on art he is still a standard authority, and his remarks on the antique and criticisms of the works of the old masters were highly esteemed by the artists of his own age as well as by Winckelmann, Lanzi, and other eminent critics and historians of art. His writings were published in Rome in 1788, and have been translated into various European languages.

MENG-TSE. See CHINESE LANGUAGE and LITERATURE, vol. iv. p. 127.

MENHADEN, a North American fish of the herring family, and genus *alosa* (Cuv.), which differs from the herrings (*clupea*) in having a deep notch in the centre of the upper jaw. This fish (*A. menhaden*, Storer), called also hardhead and mossbunker by the New York fishermen, varies in length from 8 to 14 inches; the color above is greenish brown, darkest on the top of the head and at the snout; upper part of sides roseate with indistinct bluish mottlings, disappearing after death; abdomen silvery, gill covers cupreous, a more or less distinct black spot upon the shoulders, and the whole surface iridescent. The body is elongated and compressed, the gill covers very large, eyes moderate, gape large, and lower jaw the shorter. This species comes into Massachusetts bay in May, and departs in November; great quantities are taken in nets around the outer islands of Boston harbor during the night; sometimes 100 barrels are taken at one haul, and such as are not ground up for bait are sold for food at about half a cent each; being rather oily, they are not very palatable, but on this account make excellent manure. A single menhaden of common size is considered equal in richness to a shovelful of barnyard manure; in some parts of Cape Cod they are sold at \$1 a thousand, and 2,500 are considered as sufficient for an acre of land; the odor arising from their decomposing bodies is sometimes almost unendurable. The oil is also of value; in 1845, 400 or 500 barrels were obtained at the Elizabeth islands by grinding up these fishes by machinery; it is used by painters, and is considered preferable to linseed oil. The number of barrels inspected has varied from a very few to

more than 2,000, this species being much more numerous on the coast in some years than in others. They are found from the British provinces to the coast of New Jersey, swimming in countless numbers near the surface, and attended by sharks, blue fish, gulls, and other predaceous species. They are never found in fresh water, being an exclusively marine species.

MENINGITIS, TUBEROULAR. See HYDROCEPHALUS.

MENIPPUS, a cynic philosopher, originally a slave, a native of Gadara in Syria, lived toward the close of the 8d century B. C. He amassed great wealth by usury, but, having been cheated out of it all, committed suicide in despair. He was the author of 18 treatises, all of which are lost. His works contained nothing serious, but abounded in jests and sarcasms. Lucian, in his "Dialogues of the Dead," makes Diogenes describe him as an old bald-headed man, in a tattered cloak, incessantly ridiculing the pedantry of his brother philosophers.

MENNO SIMONIS, a reformer of the 16th century, after whom one of the religious denominations which arose at that time was called Mennonites, born at Witmarsum, a village of Friesland, toward the end of the 15th century, died Jan. 18, 1561. Little is known of his personal history. In 1524 he was a priest in the village of Pingium. Doubts as to transubstantiation and other doctrines of the Roman Catholic church led him early to the writings of Luther. In 1531 his religious life received a powerful shock, when he witnessed in the neighboring town of Leeuwarden the beheading of one Sicke Snyder, who was put to death for having been rebaptized. Henceforth he was gradually led to the conviction that pe-dobaptism was untenable. His external connection with the Roman Catholic church was not broken off until 1535, when an Anabaptist movement was put down by force, and Menno's brother lost his life. He then declared himself openly in favor of a reformation of the church, but at the same time issued a polemic work against the views and errors of John of Leyden. The life of Menno after he had left the Roman Catholic church was one of great hardships. Driven into exile and threatened with death, he had to struggle for 25 years with poverty and want of every kind. He became teacher and bishop at Groningen, and formed congregations in Friesland and throughout western and northern Germany. The last years of his life were embittered by grave dissensions among his adherents concerning the nature of the ecclesiastical ban. They ended with the exclusion of the milder party from the church, although the sympathies of Menno were supposed to be with them. He died at Oldeslohe, in Holstein, where he had found an asylum and obtained permission to print his writings. His principal work was the "Fundamental Book of the True Ohristian Faith" (1539); his complete works, nearly all written in the Dutch language, were published at Amsterdam in 1681.

MENNONITES, a denomination of Baptists, first organized in Holland by Menno Simons, after whom they were also called, although it is still doubtful whether they were founded by him. The prevailing opinion among church historians, especially those of Holland, is that the origin of the Dutch Baptists can be traced to the Waldenses, and that Menno merely organized the concealed and scattered congregations as a denomination. For a long time they had to suffer in Holland from the national prejudice, which confounded them with the fanatical Anabaptists; and they found the less sympathy as their rejection of paedobaptism and of the oath separated them so widely from the vast majority of European Protestants. At last they found a protector and advocate in William of Orange, and in 1581 they were permitted to hold an assembly of the representatives of 12 different congregations. The degree of toleration which was granted to them varied, however, in different provinces, and it was not until 1672 that they obtained full liberty of worship. They suffered from internal dissensions, which commenced in the lifetime of Menno and increased after his death, quite as much as from external oppression. They were first divided into a rigorous and a moderate party, both of which were afterward subdivided into a number of smaller parties, which frequently combated each other with animosity. Hugo Grotius, who calls them Anabaptists, remarks that their divisions were so numerous that they could scarcely be numbered. In the 17th and 18th centuries the number of Mennonites in Holland greatly increased in consequence of the immigration of fugitive Mennonites from Germany and Switzerland, and it was estimated, toward the middle of the 18th century, at about 160,000. Since that time they have again considerably decreased. An important event in their history was the establishment of a theological seminary in 1735, which gave them an educated ministry, and gradually removed the barriers which had separated them from the other Protestant denominations. In 1795 they received the same rights as other denominations; and soon after they began gradually to drop the points of difference by which they were divided into a number of sects, and to unite into one denominational body. Their relation to most of the other denominations became at the same time so amicable that they could unite with them in general Bible and missionary societies. More recently the study of theology has made so great progress among them that some of their theologians, as Dr. Van Gilse and Dr. Hoekstra, are counted among the most distinguished theological authors of Holland. They have a foreign missionary society, which sustains one mission with three missionaries in Java. Teyler's theological society at Haarlem is a Mennonite institution. According to the Mennonite "Year Book" of 1850 (the last published by the denomination) they had then in Holland about

137 congregations and 140 ministers.—In Germany they were very numerous in the 17th century, when in Moravia alone they were supposed to amount to 111,441. But almost incessant persecution greatly reduced their number, and it was not until the revolution of 1848 that most of the German states granted them full civil rights. Since then they have again been deprived of some rights in several German states, as in Hanover, which in 1848 annulled the election of a representative of the second chamber because he was a Mennonite. Among the most distinguished German Mennonites is H. von Beckerath, in 1848 minister of finance of the German empire. Toward the close of the 18th century several thousand German Mennonites found a quiet retreat in the south of Russia, and obtained a charter from the emperor Paul, granting them freedom from military service for ever. Their number has since rapidly increased in consequence of continued immigration.—In the United States the Mennonites settled as early as 1683, in and about Germantown, Penn., where they erected a school and meeting house in 1708. In 1709 other families from the Palatinate settled in Pequea Valley, Chester, now Lancaster co., Penn. As their religious views were but little known and frequently misrepresented, they had the Dutch "Confession of Faith" translated into English and published in Philadelphia in 1727. They have since spread over a large portion of Pennsylvania, and are also found in Maryland, Ohio, Indiana, New York, and Canada.—In 1811, a number of Mennonites seceded from the main body, which they considered as having fallen off from the original faith, and founded the Reformed Mennonite society. Another body of rigid Mennonites are called the Omlsh or Amish church, after Jacob Amen, a Mennonite preacher of Switzerland in the 17th century, as also Hooker Mennonites, because they wear hooks on their clothes instead of buttons.—The numbers of the Mennonites were, in 1859, according to the leading Mennonite journals, as follows: America, 128,000 souls; Netherlands, 89,726; Russia, 28,770; Germany, 17,716; France, 5,000; Switzerland, 8,000; Java, 25; total, 222,287. A confession of faith, which is still regarded by the Mennonites as their standard, was adopted at Dort in 1632.—In doctrine and usages they agree in general with the other Baptist churches. But, like the society of Friends, they are utterly averse to oaths, to war, and to capital punishment, which they regard as inconsistent with the spirit of Christianity. They also differ from the other Baptists in the mode of baptism, as they generally baptize by sprinkling, not by immersion. They plead for this usage the authority of Menno, but the correctness of this assertion has been denied by the writers of other Baptist denominations. They observe the ordinance of foot-washing, and forbid their members to be married to any except those who have been united to the church.—A general history of the Men-

nonites is still wanting. The most important work on their history in Holland is that of Blaufot ten Cate, *Geschiedenis der Doopgezinden in Friesland, Groningen, Overijssel en Oostervriesland, Holland, &c.*

MENOBRANCHUS, or PROTEUS OF THE LAKES, a batrachian of the order *amphipneusta*, and of the division of perennibranchiate amphibia, so called because the gills are persistent and external; the order includes also the *proteus* of Europe, the axolotl, *amphiuma* or Congo snake, *menopoma* or hell-bender, and *siren* or mud eel of the United States. In the genus *menobranhus* (Harlan) or *necturus* (Raf.), the head and mouth are large; the upper jaw with a series of small sharp-pointed teeth, the palate also similarly armed; neck contracted, with 8 branchial tufts on each side; tail compressed laterally and fringed with a delicate membrane; limbs 4, each 4-toed; eyes small and without lids; the lips are thick and fleshy; the tongue is large, entire in front, and movable only at the tip and anterior edges; nostrils small and near the margin of the upper lip; the body elongated and sub-cylindrical, covered with a smooth skin; toes without nails. The best known species is the spotted menobranhus (*M. maculatus*, Barnes), about 12 inches long, of a cinereous dusky gray, with sub-circular darker spots, and a brown stripe extending from the snout over the eyes; it is found in the great lakes of North America and in Lake Champlain, and in the streams opening into them. A species described as *M. hyemalis* in the "Proceedings of the Boston Society of Natural History" (vol. vi., 1857), from Portage lake, a tributary of Lake Superior, may be a variety of the above. In *M. lateralis* (Say) the color is dusky brown above, with a dark band from the nostrils through the eye and along the sides to the tail, and dirty flesh-colored below; the form is more slender than in the other species; it is found only in the western waters running into the Mississippi, especially if not entirely on its eastern side, from Pennsylvania to Tennessee. In many specimens kept alive by the writer, some of them for 8 or 4 years, obtained from Portage lake, the gills, 8 in number on each side, were provided with an immense number of very delicate fringes, of a deep red color when the animal was actively breathing, which were kept waving to and fro in a most graceful manner during respiration, like a lady's feather fan; the 4 limbs, about an inch long, were set almost at a right angle, and the gait was consequently very awkward; the movements executed by the tail are rapid and graceful; the vent is longitudinal; the general aspect of the head is snaky and forbidding, and they are considered by the Indians, though doubtless erroneously, as venomous. The specimens above mentioned were very tenacious of life, having been imprisoned under ice half an inch thick every night for 8 months without apparent injury, and ate nothing for 6 months except what they obtained from the water; they often come to the surface to swal-

low air, which is emitted at the gill opening in bubbles accompanied by a faint squeak. Generally sluggish in their motions, and avoiding the sunlight, they seize living worms eagerly, sucking them down if small at a single gulp, or, if large, by repeated efforts; the sight is not very good, and they rarely snap at their prey unless it touches their mouth. They are sometimes taken on hooks by persons angling for mud fish; they are most active at night, moving rapidly at this time, and often throwing themselves nearly out of water; they feed on insects, worms, small crustaceans, and other living prey. The gills when inactive shrink, and become of a slaty gray color; they are cleansed from impurities by means of the fore feet. When the branchial fringes are lost by accident (*op. cit.*, p. 428), the animals do not appear to suffer; they have rudimentary lungs or pulmonary sacs, which assist in respiration by means of the swallowed air; but these are not sufficient of themselves to support life, as the animals die out of water in about 4 hours; with the cutaneous respiration, active in all amphibians, the air sacs are able to purify the blood. These animals, having both lungs and gills, though the former are insufficient to prolong life except for an hour or two, probably come as near as any to the fabulous amphibians able to live in water or air.

MENOPOMA, a North American tailed batrachian reptile, one of the series of animals which seem to connect the perennibranchiate amphibians with the salamanders. The genus *menopoma* was established by Harlan in 1825, though Leuckhardt had in 1821 formed the genus *cryptobranchus*. The generic characters are: large and flat head; upper jaw with 3 concentric series of minute teeth, the inner the less extensive, lower jaw with a single series; a single branchial orifice on each side; branchiae rudimentary and evanescent; extremities 4, the anterior with 4 fingers, the posterior with 5, short and palmated; skin loose and folded on the sides of the body. The common *menopoma* (*M. Alleghaniense*, Harlan) attains a length of about 15 inches, of which the head is $1\frac{1}{4}$ and the body 9; the large mouth is provided with thick lips, and the snout is full and rounded; the nostrils anterior and very small, the eyes minute and black; no cutaneous fold at the throat; body stout and thick, the vent a circular fringed orifice; tail large, much compressed laterally, with a rayless cutaneous fin along the upper border. The color is said by De Kay to be pale slate, mottled with dusky. It lives in fresh water, and is carnivorous and voracious, feeding on fish, worms, and mollusks; it is found in the Alleghany river and its tributaries, and many of the branches of the Ohio and Mississippi; its most common name is "hell-bender." Dr. Holbrook describes another species (*M. fuscum*), from western South Carolina, of a brownish color above and yellowish white below; both species have the limbs more or less fringed posteriorly.—Van der Hoeven

places the gigantic salamander of Japan in the genus *cryptobranchus*, under the name of *C. Japonicus*. This animal, the largest of the known naked amphibia, growing to a length of more than 8 feet and to a weight of nearly 20 lbs., was discovered by M. Siebold, who had several specimens alive, and one for many years in Europe. The form is robust; the tail occupies about $\frac{1}{3}$ of the length, and constitutes the principal organ of locomotion, assisted by a loose fold of skin extending from the head along the sides to the origin of the tail; the lips are not very distinct, and the tongue is small; the occiput is separated from the neck by two wide protuberances formed by the muscles of the jaws; the skin above is covered with numerous rough prominences, which give it a very forbidding appearance; the color is dark brown, with wide blackish spots. Van der Hoeven maintains that this is not distinguished from menopoma by any generic character; it resembles the latter in form, habits, bones of the skull, number of vertebræ (20 in the trunk and 24 in the tail), sternum, pelvis, ribs, and extremities; the bones present cavities opening externally; there is no gill aperture, and the branchiæ disappear early. It is slow in its movements, remaining quiet at the bottom of the water, rising to the surface every 5 or 10 minutes to breathe air both by the nostrils and the mouth, but able to remain half an hour under water without renewing the contents of the lungs; generally inoffensive, it will bite severely when irritated; it is voracious, feeding upon fish, frogs, insects, and even its own species, which it seizes with a sudden movement of the head; after eating, it generally fasts a week or two, and it is less voracious in winter than in summer; it is able to endure extremes of heat and cold, and has a remarkable power of reproducing lost parts; on land its motions are very awkward and slow. This species is confined to the lakes and streams of the high mountains of Nippon, between lat. 34° and 36° N., and to some other parts of Japan and parts of China; it is employed by the native physicians, in the form of food, as a preservative against contagious diseases and as a remedy in pulmonary complaints. The remains of the gigantic salamander found in the tertiary fresh water formations of Ceningen, formerly regarded as fossil human bones, the *homo diluvii testis* of Scheuchzer, are referred to this genus by Van der Hoeven, under the name of *C. primigenius*; in size, form, and structure it comes near to the Japanese species, and is one of the most interesting of the antediluvian animals which inhabited the fresh waters of Europe. The famous footprints of Hildburghausen, Germany, on which was established the *cheirotherium* of Dr. Kaup, have also been referred to a similar salamandroid batrachian. (See LABYRINTHODON.)—Another batrachian which deserves mention here, having been omitted in its alphabetical order, is the *amphiuma* or Congo snake of the American negroes. The general aspect is eel-

like, the head large, the lips thick and extensive, the snout depressed and rounded, neck contracted with a transverse fold at the throat; numerous small teeth on the maxillary and palatine bones; a single spiracle on each side of the neck; limbs 4, the anterior very small, with 2 fingers, and the posterior still smaller, with 2 toes. This description answers to the *A. means* (Garden), found in the southern and south-western states, and attaining a length of 28 inches, of which the head is 2 and the tail 6 inches; the color is deep bluish black above, with a violet tinge, the lips and throat lighter, and the under surface dark purple. Though the branchial apertures are persistent, the gills disappear early in life. They live in muddy waters or in the mud, burrowing like worms in the ditches of the rice fields, and feeding on small fish, mollusks, and insects; they are sometimes found on land, apparently seeking a favorable locality. They are considered by the southern negroes as highly venomous, but without any foundation in truth. In the *A. tridactylum* (Cuv.), the anterior fingers are 8, and the posterior also 8; the different number of fingers is the principal distinction between this and the other species; it is found in the south-western and perhaps in some of the middle western states of America.

MENSES. See CATAMENIA.

MENSURATION, the art of measuring things which occupy space; that is, of determining the ratio which given quantities in space bear to some quantity selected as a unit. This is the art which led to the formation of the science of geometry; and some schools of philosophy are inclined at the present day to limit the whole domain of mathematics to the field of mensuration, but extending this field so as to include time as well as space. The art is, however, partly mechanical as well as mathematical, and even in its mathematical part is but the application or illustration of sciences that in their purity have no connection with material things.—There are 3 kinds of quantity in space, viz., length, surface, and solidity; and there are 3 distinct modes of measurement, viz., mechanical measurement, geometrical construction, and algebraical calculation. For the last two modes arithmetical computation is a necessary adjunct; for the ratio to a unit quantity can be definitely stated in particular cases only as a numerical ratio. Lengths are measured on lines, and the measure of the length of a line is the numerical ratio which the line bears to a recognized unit of length, the inch, foot, or mile, determined in England and in this country by reference to brass rods 3 feet in length kept by the government as standards. The mechanical mode of determining lengths is called direct measurement. Rods are directly compared with the standard, and accurately made of the same length, and these rods, "rules," or yard sticks, or else tapes and chains accurately graduated by direct comparison with such rules, are stretched side by side with the line to be meas-

ured, and the ratio observed. When the line is long and the rule is applied many times consecutively, the slight errors arising at the joining of the successive positions of the rod, being multiplied, become of serious practical importance. In geodesy, therefore, when base lines several miles in length are to be accurately determined by direct measurement, the rods are made capable of a microscopic adjustment at the ends, and allowance is made for their expansion by heat. (See COAST SURVEY.) When the line is long, or when it is inaccessible, the length is usually measured by the second or third mode.—The measurement of a line by geometrical construction is effected by the direct measurement of accessible lines and angles in a figure, of which the line to be measured forms a component part, and then drawing this figure upon paper, on a definite scale of a certain number of feet to the inch. The direct measurement of the unknown side upon the paper will evidently give the length of the line represented by it. Thus, if one ship has sailed 50 miles E., and another from the same port 100 miles 80° E. of S., and we wish to know their distance apart, we may draw a line one inch in length and a line half an inch in length, making an angle of 60° with each other, and we shall find their extremities separated by .866 of an inch, showing the ships to be 86.6 miles asunder. (It will be noticed that we do not include angles among quantities in space. Strictly an angle is a quantity, since it can be measured, and its measurement is necessary at times for the measurement of other quantities. But the measurement of angles is not, in the general use of language, included among the direct objects of mensuration.) The measurement of a line by algebraic computation is effected as in geometrical construction, except that instead of drawing the figure we calculate the length of the unknown side from the known relations of the sides and angles of figures, and from tables giving numerical values for those relations in right triangles, into which all plane figures can be divided at pleasure. It is, in practice, easier to measure angles with great accuracy than long lines, and hence in geodesy only one base line is actually measured, while all the other distances of the survey are computed from the measurement of the angles in a network of triangles.—The second kind of quantity to be measured is surface. The area of a surface is its numerical ratio to a square of a line whose side is a linear unit, that is, to a square foot, square inch, &c. This sort of measurement is never done directly or mechanically, but always by the measurement of lines, and generally by the use of the geometrical proposition, that all surfaces may be resolved into triangles, and that the area of a triangle is equal to half the product of its base and altitude, or, what is the same thing, to the product of its base and half its altitude. The reduction of all

propositions requires sometimes so much labor, that in surfaces of a more intricate form use is made of algebraical laws and of the differential calculus, according to the fundamental idea of fluxions, that a surface is generated by a moving line which constitutes, in two positions, two of the boundaries of the surface. Thus a circle may geometrically be considered as composed of an unlimited number of triangles with their bases on the circumference and their vertices in the centre; or it may be considered algebraically as generated by a chord sweeping across it, beginning of no length, swelling to a diameter through the centre, and contracting again to zero. Either of these modes of viewing it leads to the same area of the circle, viz. the product of its circumference by half its radius, or, what is the same thing, .78539 of the square enclosing it.—The third species of quantity is solidity. The unit of measurement is here either a cube whose edge is a linear unit, or else it is an arbitrary number of cubic inches selected from historic reasons as a unit, such as the bushel of 2,150 inches, or the gallon of 231 inches. The direct or mechanical measurement of solidity is applied to liquids, or to solids separated into parts so small as to be handled somewhat in the manner of a liquid, as grains, for example, are poured from a basket. The direct measurement consists then in simply filling a vessel of known capacity with the article to be measured, repeatedly, until all is measured. The geometrical and algebraical modes of measuring solidity will be understood from the analogous modes of measuring lines and areas. They are principally based on the doctrines, that the solidity of a right parallelepiped is found by multiplying the area of its base by its altitude; that a pyramid has one third the solidity of a parallelepiped of the same base and altitude; and that every solidity by surface ingenuity can be divided into pyramids and parallelepipeds. But in intricate cases it is easier to use fluxions, and consider the surface generated by the motion of a surface than to divide it; a hemisphere, for example, might be considered as an unlimited number of pyramids with their apices at the centre, or as generated by the circular plane of its base, diminishing as it rose to the summit of the hemisphere, and becoming zero. In practical life, men use arithmetical rules or formulas derived from considerations such as we have here presented. The cask or barrel, for example, is treated as though one of several varieties of geometrical solids, and rules given for discovering its capacity on those suppositions. The gauge is a rod marked with the number of gallons a cask of certain form (about the average of barrels) would have if its diagonal from the centre of the bung to the inner end of the staves were the same as from the bung rod to the spot where that number is marked, and thus by thrusting the rod diagonally into the bung hole of any ordinary cask, the number of gallons it contains is readily determined.

tonnage of ships is computed in the same way by assuming the figure of the ship to be of a certain model, and the tonnage is under or over estimated according to its departure from this average form. Many little works have been published containing only practical rules without explanation, all essentially alike. In particular cases, ingenuity may devise particular modes for measuring the solidity or the area of very complicated figures; the earliest example is that of Archimedes determining the solidity of Hiero's crown by plunging it into water to discover how much of the fluid it displaced.

MENTCHIKOFF. I. **ALEXANDER DANILOVICH**, prince, a Russian statesman, born in Moscow about 1672, died in Berezov, Nov. 2, 1729. The son of poor parents, he was brought up without education, and apprenticed to a baker; but having attracted the attention of Lefort, the favorite of Peter the Great, he entered the service of that prince, and subsequently commended himself greatly to his patron's favor by discovering a conspiracy among his guards. He served in the campaign of Azof, accompanied the czar to Holland and England, and on the death of Lefort became his principal adviser, being equally active in preparing or executing the great schemes of national reform, and in the warlike and diplomatic operations against Charles XII. Created field marshal and prince by his master, and prince of the German empire by Leopold I., he also repeatedly officiated as regent in the absence of Peter. During the campaign of 1706 he gained the decisive battle of Kalish over the Swedes, and in 1709 he greatly contributed to the victory of Pultowa, in consequence of which Charles fled to Turkey, and his general Lewenhaupt surrendered to Mentchikoff. In the following year he commanded the Russian forces in the north, took Riga, occupied Pomerania and Holstein, and conquered Stettin. Numerous arbitrary acts, however, the main spring of which was the prince's unbounded cupidity, finally drew upon him the wrath of Peter, who subjected him to a court martial. He was sentenced to death, but escaped with a heavy fine. He regained his influence under Catharine I. (1725-'7), of whose accession to the throne he was the principal instrument, and till her death exercised full sway over Russia. He was, if possible, still more powerful at the beginning of the reign of the young Peter II., whose father-in-law he was about to become when he was suddenly overthrown by Dolgoruki (Sept. 1727), and banished with his family to Siberia. He first bore his misfortunes with great firmness, but the loss of his wife and eldest daughter broke his spirit, and hastened his death. The remaining members of the family were recalled by the empress Anna. II. **ALEXANDER SERGEYEVITCH**, prince, great-grandson of the preceding, and Russian admiral, born in 1789. He entered the imperial service in 1805, was for some time attached to the embassy at Vienna, accompanied Alexander as aide-de-camp during the campaigns of 1812-

'14, and was subsequently promoted to the rank of general, but resigned in 1828, together with Capo d'Istria and others, when the czar definitively abandoned the cause of the struggling Greeks. Under Nicholas he served as ambassador in Persia, as well as in the war with that country which broke out on his return, and soon after in the Turkish war of 1828-'9. He took Anapa, but was seriously wounded before Varna, and subsequently devoted himself to the restoration and development of the Russian navy, being successively appointed governor-general of Finland, admiral, and minister of the marine (1836). Toward the close of the same reign he was sent to Constantinople, with an imposing suite, to urge the claims of Nicholas in the affairs of Turkey (March, 1853). His extravagant behavior, as was anticipated, promoted a speedy rupture, the prince returned to Russia, and war was declared. The first victory of the Russians over the Turkish fleet at Sinope may have been in part the result of Mentchikoff's previous reconnoitings in Turkey. Commanding both the land and naval forces in the Crimea, he lost the battle of the Alma, but succeeded in strengthening the fortifications of Sebastopol, sacrificed a part of the fleet to bar the entrance of the harbor, and, though he lost another battle at Inkermann, distinguished himself by the utmost energy in defence of the fortress. He was, however, superseded in March, 1855, by Gortchakoff, and appointed by Alexander II. commander of Cronstadt. He is counted among the staunchest members of the national or old Russian party, and is regarded as opposed to reforms.

MENTOR, son of Alcimus, and friend of Ulysses, who intrusted to him the care of his house on his departure from Ithaca. To him fell the care of young Telemachus, and Minerva assumed his form in accompanying the latter on the journey in search of his father, acting the part of a wise counsellor to him. The name is metaphorically applied to any sage adviser or monitor.

MENTZ (Ger. *Mainz*; Fr. *Mayence*), a town of Hesse-Darmstadt in the province of Rheinhesen, and the most considerable fortress of the German confederation, situated on the left bank of the Rhine, nearly opposite its junction with the Main, connected by a bridge of boats nearly 1,700 feet long with the opposite village of Castel, and within a few miles of the watering place of Wiesbaden; pop. about 38,000, exclusive of the military. The finest squares are the Parade-Platz and the Gutenberg-Platz, the latter containing Thorwaldsen's statue of Gutenberg, who was born in Mentz. The cathedral is of great antiquity, and contains monuments of St. Boniface, the apostle of Germany, and of many of the archbishops of Mentz; a monument modelled by Schwanthaler was erected in 1843 by the ladies of Mentz in honor of the minstrel Meissen, called Frauenlob, who had made the praises of the ladies the theme of his songs. The other principal churches are those of St.

Stephen and St. Ignatius. The old electoral palace contains a fine museum of Roman antiquities and other artistic and scientific collections, including the famous astronomical clock by Alexius Johann, and the town library of upward of 90,000 volumes, comprising many ancient MSS. and the first psalter printed by Gutenberg. The grand ducal palace, originally the house of the Teutonic order, was for some time the residence of Napoleon I., and is now occupied by the military governor. The town possesses an excellent gymnasium, originally a university, and a number of other educational and charitable institutions; also an arsenal, a theatre, public gardens, and environs celebrated for their magnificent scenery. During the summer months Mentz is thronged by tourists. The manufactures consist of leather, tobacco, hardware, furniture, soap, pianofortes, carriages, &c. The chief articles of trade are wine, corn, and timber. The celebrated sparkling hock is made in Mentz. The opposite village of Castel is included in the system of fortifications. Its means of defence consist of 4 strong forts, beside the fortified island of Petersau. Exclusive of Castel, the extent of the fortifications of Mentz, comprising the citadel and other strong works, is 5 miles; but the united works of Castel and Petersau are of still greater extent, rendering the place a chief bulwark against French invasion, and one of the most important fortresses of Europe. The united works consist of 14 large and 18 smaller bastions. On the land side are 4 gates with double drawbridges, beside a number of gates on the river side. In times of peace the garrison consists of about 10,000 Austrian, Prussian, and Hessian troops; in times of war at least 30,000 men are required. The military governor holds office for 5 years, and is alternately an Austrian and a Prussian general.—Mentz is of remote antiquity, and has remains of a Roman aqueduct and a monument of Drusus, who is said to have founded the fortress of Moguntia or Moguntiacum on the side where Castel now stands. The town which sprung up near it was enlarged by Charlemagne. The most important epoch of its history commenced with St. Boniface, the apostle of Germany, in the 8th century, who was archbishop of Mentz. In the 13th century Mentz stood at the head of the league of the Rhenish towns. In 1486 it was annexed to the electorate of Mentz. During the 80 years' war the fortress was successively taken by the imperialists, Swedes, and French. In 1792 it fell by treachery into the possession of the French general Custine, but was reconquered by the Prussians under Kalkreuth, July 22, 1793. By the peace of Lunéville (1801) it was allotted to France, and by the congress of Vienna to the grand duke of Hesse-Darmstadt, but the fortress was assigned to the German confederation. The powder magazine of the fortress blew up Nov. 18, 1857. This terrible explosion involved a great loss of life and property, one entire street having been completely destroyed; the

damage was estimated at upward of \$1,000,000.—The former electorate of Mentz, founded at the end of the 10th century, comprised a population of upward of 200,000, and played an important part in the ecclesiastical and political history of the German empire, particularly during the reformation. Several of the electors gained great distinction, particularly Archbist. Albert in the 16th century. The last of them, Frederic Charles of Erthal, died in 1802.

MENU, or MANU. See BRAHMA.

MENZEL, KARL ADOLF, a German historian, born in Grünberg, Lower Silesia, Dec. 7, 1774, died in Breslau, Aug. 19, 1855. He studied at Breslau and Halle, officiated for many years as professor until 1824, and afterward took a prominent part in the official supervision of education in Silesia. He wrote *Geschichte Schlesiens* (8 vols., Breslau, 1807-'10); *Die Geschichte der Deutschen* (8 vols., 1815-'23); and *Geschichte unserer Zeit seit dem Tode Friedrichs II.*, a continuation of Becker's universal history (2 vols., Berlin, 1824-'5). His *Neuere Geschichte der Deutschen von der Reformation bis zur Bismarck'schen Zeit* (15 vols., Breslau, 1826-'54), is the most remarkable of his productions. In politics he favors monarchical institutions, provided they are in harmony with the progressive spirit of the age. Among his later works is a *Staats- und Religions-Geschichte der Königreiche Israel und Juda* (Breslau, 1853).

MENZEL, WOLFGANG, a German critic and author, born at Waldenburg, Silesia, June 21, 1798. He is the son of a physician, served in the war of 1815, subsequently attended the universities of Jena and Bonn, officiated for 2 years as teacher in Switzerland, and in 1825 removed to Stuttgart, where he became connected with the publishing establishment of Cotta, and where he continues to reside. His writings include poetry and fairy tales, some of which, as the famous *Rübezahl*, have been translated into English and other foreign languages. He has also written a *Geschichte der Deutschen* for the use of schools and general readers (3 vols., Zürich, 1824-'5, translated into English by G. Horrocks, 8 vols., London, 1849); and more recently a *Geschichte Europas von 1789-1815* (2 vols., Stuttgart, 1853). His travelling sketches display a keen insight into character, and his descriptions of the Viennese have nowhere been described with greater fidelity than in his *Reise nach Wien*. His *Furor* (8 vols., Leipzig, 1851) is a novel which contains graphic delineations of the 80 years' war; and in the same year appeared his *Gedänge der Völker*, a collection of popular lyrics of all nations. Beside the above works and a number of others on various subjects, he has prepared an excellent manual of the history of the present century, and edited for many years past the *Literaturblatt*, which ceased to appear after the revolution of 1848; but Menzel resumed the editorship in 1852, and it has since been an organ of reactionary policy in civil and ecclesiastical affairs.—Notwithstanding his prodigious literary activity, Menzel is

chiefly celebrated as a polemical writer. In his *Deutsche Literatur* (2 vols., Stuttgart, 1828; translated into English by C. C. Felton, in Ripley's "Specimens of Foreign Literature," Boston, 1840) and other works he unsparingly attacks many German writers, and also assails the artificiality of Goethe's school as well as that of Voss. After the revolution of July, 1830, he came forward as a bitter opponent of French political and literary influence in Germany. His fierce dogmatism was castigated by Börne in his *Menzel der Franzosenfresser* (Paris, 1837). He has been a member of the Würtemberg legislature.

MEPHISTOPHELES, the familiar spirit of the magician Faust, the second of the fallen archangels, and the most powerful chief of the infernal legions after Satan. The name occurs in mediæval legends, and is perhaps derived from the Greek *μη*, not, *φως*, light, and *φίλος*, loving. He is chiefly known as the malignant, scoffing, and relentless fiend of Goethe's "Faust."

MEQUINEZ, or **MEKNAZA**, a city of Morocco, in the province of Fez, near the Leboo, 80 m. W. S. W. from Fez; pop. about 50,000. It is situated in a large and fertile plain, and is surrounded with walls. The houses are in general only one story high, but are neat and well built. The principal edifice is the extensive palace erected by Sultan Muley Ismael, and occasionally the residence of the sovereign. It is built of marble, and is adorned with fountains and fine gardens. There are manufactures of painted crockery, leather, &c. In the vicinity are large plantations of olives. There is an extensive trade at Mequinez in most of the products of the country.

MERCATOR, **GERARD**, a Flemish geographer and mathematician, born in Roermond, March 5, 1512, died in Doesburg, Dec. 2, 1594. He was patronized by the emperor Charles V., and in 1559 was appointed cosmographer to the duke of Juliers and Cleves. He published from time to time descriptions and maps of Europe, France, Germany, the British isles, and the world. His method of laying down charts and maps, by a projection of the surface of the earth in *plano*, is still in use, and bears his name. (See MAP.) The most important of his works are: *Chronologia a Mundi Exordio ad 1568* (Cologne, 1569); *Tabulæ Geographicae ad Mentem Ptolemæi restitutæ* (1578); and *De Creatione ac Fabrica Mundi*, a treatise prefixed to the uniform edition of his maps (1594).

MERCER, the name of counties in 7 of the United States. I. A W. co. of N. J., bordering on the Delaware river, and drained by Assunpink and Stony creeks; area, 260 sq. m.; pop. in 1855, 32,722. The surface is uneven, somewhat elevated toward the N., and the soil fertile. The productions in 1850 were 124,734 bushels of wheat, 468,670 of Indian corn, 876,123 of oats, and 17,793 lbs. of wool. There were 14 grist mills, 20 saw mills, 8 iron foundries, 6 woollen factories, 3 cotton factories, 4 tanneries, 3 churches, 1 college, and 8,586 pupils attending public schools. It is traversed by the New

Jersey and the Camden and Amboy railroads, and the Delaware and Raritan canal. Capital, Trenton. II. A W. co. of Penn., bordering on Ohio, drained by the Shenango and several smaller creeks; area, 624 sq. m.; pop. in 1850, 33,172. The surface is undulating and the soil fertile; extensive coal mines are found, as also iron and limestone. The productions in 1850 were 206,729 bushels of wheat, 268,710 of Indian corn, 385,976 of oats, and 218,859 lbs. of wool. There were 28 grist mills, 24 saw mills, 5 iron foundries, 2 woollen factories, 12 tanneries, 61 churches, and 8,615 pupils attending public schools. The Beaver and Erie canal intersects the county. Capital, Mercer. III. A S. W. co. of Va., bounded E. by the Kanawha, intersected by Blue Stone river, and drained by various creeks; area, 540 sq. m.; pop. in 1850, 4,222, of whom 177 were slaves. A range of the Alleghanies extends along the N. W. border. The productions in 1850 were 12,284 bushels of wheat, 105,946 of Indian corn, 85,280 of oats, and 12,949 lbs. of wool. Value of real estate in 1856, \$639,580, being an increase of 54 per cent. since 1850. Capital, Princeton. IV. A central co. of Ky., bounded N. E. by the Kentucky river, E. by Dick's river, and drained by the head waters of Salt river; area, 240 sq. m.; pop. in 1850, 14,067, of whom 3,260 were slaves. Its surface is undulating and soil fertile. The productions in 1850 were 1,098,895 bushels of Indian corn, 143,990 of oats, 12,420 lbs. of tobacco, and 47,850 of wool. There were 50 grist mills, 15 saw mills, 8 cotton factories, 5 tanneries, 28 churches, 1 college, and 1,528 pupils attending public schools. Capital, Harrodsburg. V. A W. co. of Ohio, bordering on Ind., drained by the St. Mary's and Wabash rivers and branches; area, 576 sq. m.; pop. in 1850, 7,712. It has a level surface, heavily timbered, and a fertile soil. The productions in 1850 were 51,661 bushels of wheat, 149,506 of Indian corn, 84,918 of oats, and 11,656 lbs. of wool. There were 2 grist mills, 4 saw mills, 1 tannery, 11 churches, and 1,835 pupils attending public schools. Capital, Celina. VI. A N. W. co. of Ill., on the Mississippi river, and bordering on Iowa, drained by Edward's and Pope's creeks; area, 550 sq. m.; pop. in 1855, 9,660. There are extensive prairies in the county, and it is heavily timbered along the banks of the Mississippi; the soil is fertile. The productions in 1850 were 108,479 bushels of wheat, 480,991 of Indian corn, 60,159 of oats, and 19,498 lbs. of wool. There were 8 grist mills, 11 saw mills, 8 churches, and 196 pupils attending public schools. Capital, Keithsburg. VII. A N. co. of Mo., bordering on Iowa, drained by Weldon river and several creeks; area, 580 sq. m.; pop. in 1856, 5,608, of whom 23 were slaves. It has an undulating surface and fertile soil. The productions in 1850 were 7,311 bushels of wheat, 149,555 of Indian corn, 26,500 of oats, and 8,575 lbs. of wool. Capital, Princeton.

MERCER, **HUGH**, an American revolutionary general, born in Scotland about 1720, died near

Princeton, N. J., Jan. 12, 1777. He was educated as a physician, and served as a surgeon's assistant in the army of the young pretender at the battle of Culloden. Emigrating soon after to America, he settled in Virginia, and resided there in the practice of his profession until 1755, when he volunteered in the expedition led by Braddock to Fort Duquesne. At the disastrous battle of Monongahela, July 9, he was severely wounded in the shoulder, and, unable to keep up with the fugitives, wandered alone through the wilderness to Fort Cumberland, 100 m. distant, where he arrived almost exhausted by sickness, famine, and fatigue. He subsequently returned to his practice, but at the outbreak of the revolution promptly joined the continental army, and through the influence of Washington obtained the rank of brigadier-general with the command of the flying camp organized in the spring of 1776. He subsequently accompanied Washington on his retreat through New Jersey, and rendered valuable assistance at the battle of Trenton. In the succeeding action at Princeton he led the vanguard, composed principally of militia. His men beginning to waver before the attack of the enemy, he made an energetic attempt to rally them, and was felled to the ground by a blow from the butt end of a musket. Though surrounded by British soldiers, he rose and defended himself with his sword, refusing quarter, and after a brief struggle, in which he was repeatedly bayoneted, was left for dead upon the field. He was removed soon after the battle to the house of a Mr. Clark in the neighborhood, where a week afterward he died in the arms of Major Lewis, Washington's nephew and one of his aids. His corpse was followed to the grave in Philadelphia by upward of 80,000 people. In Nov. 1840, a monument to his memory was dedicated at the Laurel Hill cemetery.

MERCER, JESSE, an American clergyman, born in Halifax co., N. C., Dec. 16, 1769, died in Butts co., Ga., Sept. 6, 1841. He was ordained to the Baptist ministry in his 20th year, and took charge of a church in Wilkes co., Ga. In 1798 he was a member of the convention to amend the constitution of the state of Georgia, in which body his services proved highly valuable. At this convention it was proposed by a member of the legal profession that ministers of the gospel be declared ineligible to seats in the state legislature. Mr. Mercer moved, as an amendment, that both lawyers and doctors be included in the provision, which caused the original mover to withdraw his motion. He was at one time a candidate for state senator from Wilkes co., but was defeated. He was also solicited to offer himself for governor, but refused. He was an eloquent preacher, and had much influence with his denomination. "Mercer's Oluster," a volume of hymns compiled by him, is still in use with various Baptist congregations. Mercer university, in Penfield, Ga., to which he left most of his estate, was named in his honor.

MEROERSBURG, a post borough of Franklin co., Penn., 15 m. S. W. from Chambersburg, and 62 m. S. W. from Harrisburg; pop. in 1850, 1,184. It is the seat of Marshall college, which was founded in 1836, under the direction of the German Reformed church, and has 6 professors and 165 students, and a library of 8,000 volumes. A theological seminary, with a library of 6,000 volumes, and a law department, are attached to the college.

MERCHANT, COMMISSION. See FACTOR.

MERCIA, the largest kingdom of the Saxon heptarchy in the island of Britain. It was situated inland, being bounded N. by Northumbria, E. by East Anglia and Essex, S. by Wessex, and W. by Wales, and included the modern counties of Chester, Derby, Nottingham, Lincoln, Salop, Stafford, Leicester, Rutland, Northampton, Huntingdon, Hereford, Worcester, Warwick, Gloucester, Oxford, and Buckingham, and parts of Hertford and Bedford. It was founded by Crida, an Angle, in 585, was afterward subject for a time to the Northumbrians, and after overcoming East Anglia and Kent, was finally conquered by Egbert, king of Wessex, in 825.

MERCK, JOHANN HEINRICH, a German scholar, born in Darmstadt, April 11, 1741, died by his own hand, June 27, 1791. He officiated in various public functions in his native town, translated Addison's "Cato" and other works from the English, cooperated with Lavater in the publication of his work on physiognomy, and took an active part in the *Frankfurter gelehrten Anzeigen*, *Deutscher Merkur*, and other leading periodicals, and in various other literary enterprises. His select works were edited long after his death by Stahr, and published in Oldenburg in 1840. He is chiefly remembered, however, in German literature on account of his intimate association with Goethe, Herder, and other eminent men, upon whose intellectual development he exerted a great influence by the boldness of his literary criticism. The latter part of Merck's life was saddened by domestic and pecuniary misfortunes which led him to shoot himself. The letters addressed to him by Goethe, Herder, Wieland, &c., were published in 1835; and another edition of his correspondence, including both letters received and written by him, appeared in 1838.

MERCURY, or QUICKSILVER, a metal of the color and lustre of silver, and fluid at ordinary temperatures, whence its ancient name of *argentum vivum*, and that by which it was called by Aristotle and Theophrastus, who made the earliest mention of it, *aprypor xuros*, fluid silver. It was also known as *hydrargyrum*, and from this its chemical symbol, Hg, is derived. The equivalent of the metal is 100; and its specific gravity, which varies somewhat with the temperature, is given by Kopp as 13.557 at 62.6° F. At 39° or 40° below zero the metal becomes solid and crystallizes in regular octahedrons, contracting in bulk and assuming the density of 14; the mass is malleable, and resembles lead. Its boiling point is 682°, at which it forms an

invisible, transparent vapor, the density of which is 6,976, air being 1,000. Before assuming this form, if exposed to the air at high temperatures, it absorbs oxygen and is converted into the red oxide, which is decomposed at the boiling point. Above 40° mercury is somewhat volatile, as may be shown by holding an iodized daguerreotype plate, that has been submitted to the action of light in the camera, over a bath of mercury, when the picture will be brought out by the vapor. Gold leaf is also affected by the vapor when suspended in a vial containing mercury and kept at ordinary temperatures. Strong nitric acid dissolves mercury; but hydrochloric acid, hot or cold, does not affect it. It is oxidized by heated concentrated sulphuric acid. Exposed for a long time to the air, mercury gathers a film of oxide of gray color upon its surface, which adheres to the glass in which the metal is contained. When mercury contains dissolved in it lead, zinc, or other extraneous oxidizable metals, these may be removed by covering the surface of the metal, placed in a shallow vessel, with dilute nitric acid, and stirring frequently. The acid attacks and takes up the foreign matters, and may also form a crust of nitrate with a small portion of the mercury. This is a more efficient method of purification than that of distillation when zinc is present, as this is distilled over with the mercury. Impurities mechanically mixed with mercury may often be removed by straining the metal through paper perforated with a very small hole, or squeezing it through wash leather. But if a film of oxide still adheres to the mercury, this may be removed by agitating it violently in a bottle in which some powdered white sugar has been introduced, then blowing air into the bottle, repeating the shaking and blowing several times, and then filtering. Mercury has the property of uniting with various metals, as gold, silver, tin, lead, zinc, and bismuth, and forming compounds, which are noticed under the head of AMALGAM. In some cases the cheapest of the metals named have been used to adulterate mercury. The effect of this mixture is to produce an amalgam, the presence of which is easily detected by the fluid, when poured upon a plate of glass or porcelain, not flowing freely, but leaving a trace behind it.—Mercury occurs native, and also as an amalgam combined with silver; but these are comparatively unimportant as sources of its supply. The native metal is met with in globules scattered through the masses of rock that contain the veins of its ore, and also in the gangue of these. Sometimes it collects in the cavities in quantities sufficient to be gathered up. In the alluvial deposits near Huancavelica in Peru, it has been found to the amount of 600 lbs. in digging a ditch not over 6 feet in depth. But the chief source of the metal is its ore, the sulphuret, of which an account has been given under CINNABAR. Its veins and beds are found in geological formations of almost all ages, and particularly in talcose and argillaceous slates,

and in the shales of the silurian period. The coal measures and the old red sandstone also contain them. The ore is more or less mixed with the wall rocks of the veins, and the stuff is often worked to profit when its percentage of metal amounts to 3.8 lbs. per ton. When separated from these by roasting in suitable furnaces, the metallic vapors are condensed and the mercury is transferred into bottles of wrought iron, or into leather bags. The bottles, called flasks, imported into the United States from the Spanish ports, and principally from Cadiz, contain 76½ lbs. of mercury. The Austrian product is shipped from Trieste in bags formed of whole skins of white leather, which contain 31 lbs. each, and are packed 4 together, with straw, in a rough sort of flat keg.—The Spanish mines of Almaden in the province of La Mancha are the most important mines of mercury in the world, and were worked by the ancient Romans, who according to Pliny annually obtained from them in his time about 700,000 lbs. of cinnabar. The veins, chiefly of cinnabar, are found at the junction of the metamorphic rocks with silurian slates and sandstones, and are traced in an E. and W. direction between Chillon and Almadenejos, a distance of about 12½ miles. They are very conspicuous in the bare rock which forms the summit of the hill, in which the mines are worked. Two of the principal veins, one of 2 and the other of 14 feet width, are seen to meet in this hill, and at their junction expand into a bed nearly 100 feet wide, constituting the prodigious mass of ore called *el Rosario*. In consequence of this immense development, it has not been found necessary to extend the workings below 1,000 feet, notwithstanding the long time the mining operations have been going on. The Spanish government holds the title to the mines, and derives a large revenue from their product. They have long been leased to the Rothschilds and other bankers of Europe; and so large a portion of the whole product of the quicksilver of the world has been derived from them, that the price of this article has depended upon the bargain made with the government by the contractors. The opening of the California mines has, however, of late years rendered the market much more independent. Their annual product has been in the present century from 2,700,000 lbs. to 3,456,000 lbs., and this from ores the average yield of which is only about 10 per cent.—The other mines of mercury in Europe, next in importance to those of Almaden, are the Austrian mines at Idria, in Carniola. (See IDRIA.) Cinnabar is here interspersed together with some native mercury through shales and a black compact limestone of the age of the Jura limestone. These mines are controlled by the government, and their annual product, which from 1843 to 1847 averaged 358,281 lbs. per annum, was formerly larger, and has since amounted to 648,000 to 1,080,000 lbs. The greatest depth is 840 feet, and the descent is by 757 steps cut in the rock. The ore is excavated with the

pick, and in some portions of the mine the soft earthy material contains visible globules of native mercury distributed in stratiform arrangement. These sometimes occur in quantities sufficient to roll out upon the floor of the workings. Where the mine is most productive in native metal, the atmosphere is so contaminated with mercurial fumes that the miners continue working only 4 hours at a time, and, as at other mines of this character, many are always suffering from the effects of the mercury.—Other countries in Europe which contain workable mines of mercury are Hungary and Transylvania, the annual product of which has been rated at 75,000 to 97,200 lbs.; Deux Ponts, 48,200 to 54,000 lbs.; and the rest of the Palatinate, 19,440 to 21,600 lbs. The mines of these localities are in sandstones belonging to the upper part of the coal formation. They contain impressions of plants and of fishes, and the scales of the latter are sometimes converted into cinnabar, the organic matter having been a centre for collecting the mercurial deposit. The metal is met with in other parts of Europe, but not in important quantities. At Ripa, in Tuscany, cinnabar forms very small veins in mica slate. In France native mercury is found at Montpellier, disseminated through the tertiary marls and calcareous conglomerates upon which the city is built.—Upon the American continent, mines of mercury have long been worked in the Andes. In Chili the ores are found in granitic rocks, and in Peru in the sandstones associated with the coal. The mines of Huancavelica in the latter country are of great extent, and were worked as far back as the year 1566. The ores are disseminated through a body of sandstones and shales which slope together toward the W. at an angle of about 64°. No evidence of a vein is seen, but the appearance is as if the ores had been introduced in the form of vapors. The thickness of the productive belt is about 850 feet, and along this are open excavations extending a third of a mile in length, and laid out without plan in the most injudicious and dangerous method. It has often happened that portions have caved in, and at one time 200 workmen were destroyed by such an accident. From 1570 to 1789 the product of the mine, as given by Humboldt, was 1,040,469 quintals of mercury, worth, at \$78 per quintal (the price paid by the government), \$75,954,257. The quintal of Peru and Mexico is 101.61 lbs. avoirdupois. From 1790 to 1845 the product was about 66,000 quintals. The other mines of Peru are supposed to yield about as much as those of Huancavelica, and the total annual product is but little if any more than 200,000 lbs. Mercury is found at many localities in Mexico; but notwithstanding the immense consumption of the metal, amounting, it is stated, to 16,000 quintals annually, in the processes of amalgamating the silver ores, no mines of it are now worked. About the year 1844 some 400 to 500 quintals were obtained from mines near Guadalajara. Humboldt describes its occurrence at many points, and its as-

sociation at Durasno with porphyry upon which the cinnabar ore rests, while it is covered with shaly clay containing fossil wood and coal. At San Juan de la Oliva the cinnabar veins are in a pitchstone porphyry; and at the time of Humboldt's visit they had been worked to the depth of 150 feet. Upon the price of mercury depends in no small degree the successful working of many of the silver mines of Mexico. The supplies were formerly furnished by the Spanish government exclusively; and of late years the Mexicans have paid for mercury in their harbors \$120 per quintal, making it about \$165 in the mining region of Zacatecas.—In California a mine of cinnabar was opened and first worked for mercury in 1845 by Capt. Andrew Castillero. For a long time the Indians, it was found, had used this material as a paint, and had made excavations in search of it for some 50 or 60 feet into the mountain; and the Spaniards also in 1824 and afterward had made attempts to work the same ores for silver. In 1846, in consequence of the disordered state of the country, the mine was not worked. After the war, in 1848, operations were recommenced, and in 1850 a company of Mexicans and English worked the mine and continued in possession till Sept. 1858, when they were enjoined by the U. S. court from continuing their operations until the title to the property should be determined. The product up to this time had amounted, according to the legal papers presented, to over \$8,000,000, and was estimated annually at about \$1,000,000. The locality, now called New Almaden, is in one of the branch valleys of the San José, Santa Clara co., 12 m. from the town of that name, which is itself 54 m. from San Francisco. The ore is found irregularly disseminated among beds of argillaceous shales and flinty strata, supposed to belong to the silurian group, in a range of E. and W. secondary hills along which it is traced 8 to 4 m. These beds dip at a high angle and are greatly contorted. Veins of carbonate of lime traverse the rocks and the layers of ore, and displace the small veins. Few foreign minerals are associated with the cinnabar; these are pyritous iron and copper and arsenical pyrites. Rich masses of the ore yield 67.25 per cent. of mercury, 10.38 per cent. of sulphur, and 22.55 per cent. of silica, alumina, &c. The average yield of the ore is about 30 per cent. The mine is entered by a large cross-cut adit, 200 feet below the older workings, and extending 1,200 feet into the hill. Side galleries are excavated on the line of the ore deposits, following these in one instance more than 400 feet. The ore brought out and assorted is sent to the smelting works, 1½ m. down the mountain. The finer fragments are worked up with the soft loamy portion, and with water the mass is kneaded and moulded into the form of bricks. These, being dried in the sun, are worked like the rest. The furnaces for reducing the ore were 18 in number in 1854. They were 40 feet long, 8 wide, and 10 high, in rows 6 feet apart. Each furnace was divided into

compartments, the fire occupying one at the end, and the heat passing through the ores in flues. The charge for each furnace was 15,000 lbs. The working portion of the furnace connects by a flue passing upward with the first condensation chamber, the dimensions of which are 8 feet in length, 4 in breadth, and 5 in height. The chambers are covered with cast iron plates luted down. Seven other condensation chambers succeed the first, through all of which in succession the vapors pass before the uncondensable portions are conducted into a tank, where they are sprinkled by a current of water, and thence escape by a wooden chimney. From each chamber the mercury as it condenses is conveyed to an iron vessel, from which it is transferred into iron flasks, the capacity of which is 75 lbs. weight. A charge is worked off in 60 hours, and wood is used for fuel. The mercurial vapors penetrate the mason work of the chambers, and collect in the soot of the chimney and in a fine black deposit upon the roofs around. Men and animals employed about the smelting works are subject to be salivated and otherwise injuriously affected by the mercury; but no ill effects of this kind are experienced at the mines. The total value of the New Almaden property was rated by the U. S. attorney-general in a recent communication to congress at \$15,000,000. The working of the New Almaden mine being stopped, parties were led to look for other sources of mercury along the range of the ore. These were found in Dec. 1858, $\frac{1}{4}$ of a mile west from the old workings. The new locality was named the Enriquita mine, and was worked by Henry Laurencel of California for himself and others. In June, 1860, it came into possession of the "California Quicksilver Mining Association," by which it is now vigorously worked. The production has been as follows: Sept. 1859, 14,400 lbs.; Oct., 28,650; Nov., 27,525; Dec., 28,425; Jan. 1860, 27,000; Feb., 16,950; March, 25,500; April, 33,700; May, 46,275; June, 48,750; July, about 60,000. The ore on hand for August was sufficient to produce about 80,000 lbs. The total expenditure for exploration and machinery at this mine has been about \$175,000, nearly all of which is already paid for from the products. Connected with the Enriquita and owned by the same company is another mine called the Providencia, from which very rich ores have been obtained in moderate quantities. Another mine on the same range, at its extreme western portion, is worked by the Santa Clara mining company of Baltimore. It is called the Guadalupe mine, and is producing from 10,000 to 15,000 lbs. of quicksilver per month. The custom house returns previous to the opening of these mines present the following as the production of the New Almaden mine for the years named: 1853, 18,800 flasks; 1854, 20,968; 1855, 27,165; 1856, 23,740; 1857, 27,262; 1858 ($\frac{1}{4}$ of the year), 24,132; total, 142,062 flasks of 75 lbs. each, or 10,654,650 lbs. Add for California consumption 85,516 flasks, and

the grand total is 177,578 flasks, or 13,818,850 lbs.—The total production of mercury throughout the world, according to the estimates of Dumas as given above, may be thus summed up:

	Lbs. avoirdupois.	
Almaden, Spain.....	2,700,000	to 3,450,000
Idria.....	648,000	" 1,060,000
Hungary and Transylvania.....	75,600	" 97,200
Deux Ponts.....	43,200	" 54,000
Palatine.....	19,400	" 21,000
Huancavelica.....	" 324,000
California.....	" 2,000,000
Total.....	7,082,500	

—Metallic mercury in its usual form has no action upon the human system; it has been taken with impunity in quantities of a pound weight; but in vapors it acts energetically upon those exposed to their influence, producing nervous tremblings, shaking palsy, salivation, vertigo, and other disorders of the brain. When the metal has been long triturated or violently shaken in a bottle, its particles are thereby minutely divided, and they take the form of a gray powder in which the metallic appearance is lost. The particles still retain the globular form, as is proved by microscopical examination, and according to Ehrenberg they are only from $\frac{1}{128}$ to $\frac{1}{1024}$ of a line in diameter. In this condition the mercury acts as a powerful medicine, probably from its readiness in its finely divided state to enter into new combinations.—Mercury with chalk, or *hydrargyrum cum creta*, prepared by rubbing up 8 ounces of mercury with 5 ounces of prepared chalk, and blue pill made from a mass composed of one ounce of mercury rubbed up with one and a half ounce of confection of roses, and then beaten with half an ounce of powdered liquorice root, are preparations in very frequent use. When blue pill is taken in small but repeated doses, the first appreciable effect is usually an increased activity of the secretions, particularly of the intestinal canal, the discharges from which become liquid and bilious; the mucous membrane of the lungs and genito-urinary apparatus may display a similarly augmented secretion. If there happen to be anywhere an interstitial deposit of fibrine, or an exudation of lymph, or effusion of serum, its absorption may now be promoted; although Stille says if the mercurial influence be carried too far, extensive ulcers will appear, sometimes coated with false membranes or exudations, and the eyelids and ankles may become cedematous, and even general dropsy may ensue, thus producing what might very properly be called a homœopathic effect. In the next grade of unfavorable action of mercury the appetite fails, digestion is impaired, the secretions become still thinner and more copious, the firmness of the tissues diminishes, newly formed callus is dissolved, and recently healed wounds open afresh; the muscles waste, the skin has an earthy paleness, with the other consequences mentioned above. These symptoms, says Stille, appear to depend upon the radical change which the blood has undergone by losing a large proportion of its natural solid constituents, and perhaps a

portion of that vitality on which its coagulability in part depends; so that an unwonted fluidity and thinness of the blood ensues. The occurrence of salivation is too well known to need description. The power of mercury to increase the discharge of bile cannot well be questioned; as in the case of other stimulants it sometimes exceeds due limits, and may even cause, says Stille, the affection which it generally and with most certainty cures. Thus the celebrated Chapman regarded it as probable that the inordinate use of mercury may, in various ways, derange the stomach, bowels, and liver, so as to produce jaundice; and Cheyne states in as many words that mercurials actually produce jaundice; while Stille says enlargement of the liver is a more usual effect of mercury. On the nervous system the action of mercurials is decided. Stille says: "Few medicines produce such a marked sense of depression both mental and bodily as mercury even in ordinary doses; but when the system is brought thoroughly under its influence, these effects become distressing; the susceptibility to external impressions, and particularly to that of cold, is augmented, pains in the limbs are felt, slight annoyances disurb the equanimity, and sometimes mental debility ensues, so that a moody melancholy and fear of death may overtake the patient." Mercurial fever is a common effect of mercury. Beside the tendency of ulcers on any part of the body to assume an unhealthy appearance under the influence of mercury, it may develop ulcers in the mouth, on the guma, the inner surface of the lips and cheeks, and the tongue; so that many able physicians have even taken the ground that the remoter or secondary and tertiary forms of syphilis are really produced by mercury. The celebrated Bretonneau, by experiments upon animals, discovered that by an excessive use of mercury it is possible to produce symptoms having a perfect resemblance to those of constitutional syphilis, such as affections of the bones and ulcers of the mucous membranes; and that the mercurial disease attacks all those parts which are the seat of syphilis, and nearly in the same order, and assumes nearly the same external appearance.—In the arts, mercury is employed in the construction of philosophical instruments, and is preferred to other fluids for filling thermometers and barometers by reason of the great range of temperature through which it expands or contracts uniformly with equal increase or decrease of heat. Its amalgam with tin is largely used for coating or "silvering" the backs of mirrors. The paint, vermilion, is its sulphuret, cinnabar. But its principal consumption is in the extraction of silver and gold from their ores in the amalgamating process. (See AMALGAMATION.) Mercury forms two compounds with oxygen: one the suboxide or black oxide, Hg_2O ; and the other the red oxide, HgO . When prepared by decomposing the nitrate by heat, it has a bright orange color, and is known as the red oxide of mercury. In the state of a

finely levigated powder, or as an ointment, this is applied externally in medicine as a stimulant and caustic. The name red precipitate, or precipitate *per se*, was given to this oxide because of the manner in which it was formerly prepared. Mercury in a matrass (a glass vessel with a long narrow neck) was subjected continuously to the action of heat. The mercurial vapor rising in the neck of the matrass was converted into red oxide, which was prevented from escaping; and as the operation went on for weeks, the whole was converted into the same compound. Other mercurial compounds of especial interest are the subchloride and chloride, the one described under CALOMEL and the other under CORROSIVE SUBLIMATE.

MERCURY, or HERMES, an ancient deity of the Greeks and Romans. According to the Greek legend, he was a son of Jupiter and Maia, a daughter of Atlas. He was born in a cave of Mt. Cyllene, in Arcadia, whence he is sometimes distinguished by the epithet Cyllenian. Soon after his birth, escaping from his cradle, he went to Pieria, and stole several of Apollo's oxen. His cunning was as precocious as his knavery. Lest the traces of his footsteps should be discovered, he put on sandals, and drove the oxen to Pylos, where he slaughtered two for a banquet and sacrifice, and concealed the rest. On returning to Cyllene, he found a tortoise at the entrance of his cave, of whose shell, and some of the ox intestines brought from Pylos, he constructed the first lyre, on which he immediately performed. Apollo, knowing who had stolen his cattle, came presently to Cyllene to demand restitution; and when Mercury denied the theft he took him before Jupiter, who obliged him to confess. Apollo and the infant god then went to Pylos, where the former received back such of his oxen as had not been slaughtered; but when he heard Mercury perform on the lyre, he was so delighted that he permitted the young musician to retain the cattle, and presented to him his golden *caduceus*, or pastoral staff, teaching him at the same time the art of prophesying with dice. His father Jupiter appointed him herald-general of the gods, in which capacity he was frequently the medium of communication between mortals and immortals. It was he who conducted Priam to Achilles, when the venerable monarch went to beg the body of Hector from his conqueror. He bound the presumptuous Ixion to the wheel for having boasted of intimacy with Juno, chained Prometheus to the Caucasus, and escorted Juno, Venus, and Minerva to Mt. Ida to submit their charms to the judgment of Paris. Mercury was esteemed the author of various inventions indispensable to the weal of human society. The origin of letters, numbers, astronomy, music, military tactics, gymnastics, weights, measures, &c., was ascribed to him. He was also regarded as the god of eloquence, the presiding deity of the gymnasia, and the patron of fraud and perjury. The original seat of his worship was Arcadia, whence it gradually spread over the Grecian world. His festivals were

called *Hermes*. The most celebrated of his temples was that on Mt. Cyllene in Arcadia. The principal things sacred to him were the palm tree and the tortoise. He is generally represented as a young man with a broad-brimmed hat adorned with wings, in his right hand a herald's staff or a sceptre, and on his feet a pair of winged sandals.—In Rome, Mercury was the god of commerce and diplomacy. The *etyma* of his name, *merz* and *curius*, clearly indicate his predominant function. A temple was raised to him in Rome near the Circus Maximus as early as 495 B. C., and an altar of his stood contiguous to the Porta Capena. Under the cognomen of Malevolus, or the "ill-disposed," he had a statue in the *vicus sobrius*, or sober street, in which no wine shops were allowed to be kept, and there milk was the sole beverage offered to him. This statue held a purse in one of its hands as a symbol of his commercial functions. The festival of Mercury was celebrated on the 25th of May, which was regarded as a high day by the Roman merchants. After the various relations of Greece and Rome had become intimate, the Hermes of the former and the Mercurius of the latter were popularly considered to be identical, though the resemblance between the two divinities was very slight, and was never admitted by the *fetiales*, or guardians of the public faith of Rome.

MERCURY, THE PLANET. See ASTRONOMY.

MERCY, SISTERS OF, or ORDER OF OUR LADY OF MERCY, a religious order founded in Dublin by Miss Catharine McAuley in 1827. Miss McAuley was born in Dublin, of Catholic parents, Sept. 17, 1778, but being left an orphan in early childhood was bred a Protestant. Soon after reaching years of discretion she resolved to embrace the Roman Catholic faith, and to devote her life and her large fortune to the service of the poor. She induced a number of other ladies to join her, purchased a house in Dublin, and there opened an asylum for destitute young women and a free school for the children of the poor. Soon afterward, in common with her companions, as a preliminary step to the foundation of a new congregation, she underwent a regular noviceship and took the veil in a convent of Presentation nuns. The institute of which Miss McAuley thus became the foundress and first superior was approved by Pope Pius VIII. The rule of St. Augustine was subsequently adopted as the basis of the new order, but with several changes and additions, which received the approval of Pope Gregory XVI. in 1835, and his formal confirmation in 1841. From Dublin the sisters of mercy spread rapidly over Ireland, and extended to England, Scotland, and the British colonies. The first community in the United States was established in Pittsburg in 1848. The order has since been introduced into the dioceses of Baltimore, Cincinnati, Little Rock, New York, Buffalo, Brooklyn, Hartford, Portland, St. Louis, Chicago, San Francisco, and the vicariate apostolic of Florida, and into various parts of South

America. The sisters of mercy have in view, beside other charities, the visitation of the sick and prisoners, the instruction of poor girls, and the protection of virtuous women in distress. Wherever their means permit they found "houses of mercy," where destitute girls of good character are cared for until employment can be found for them. They have also the direction of several orphan asylums and hospitals in the United States. The sisters of mercy are subject to the bishops, and have no general superior, each community being independent of the rest of the order. The sisterhood is divided into two classes, choir sisters and lay sisters. The choir sisters are employed about the ordinary objects of the order, and the lay sisters about the domestic avocations of the convent and such other duties as may be assigned to them. Candidates for membership of either class undergo a preliminary "postulancy" for 6 months; at the end of that time they assume the white veil and become novices. The noviceship lasts two years. The vows, which are taken for life, bind the members to poverty, chastity, obedience, and the service of the poor, sick, and ignorant. The habit of the order is a black robe with long loose sleeves, a white coif, and a white or black veil. In the streets a bonnet of black crape is worn instead of the coif and veil.

MERGANSER, a name applied to most of the saw-billed ducks, of the sub-family *mergina*, of which the goosander, the largest species, has been described under that title. The bill is very slender, narrow, compressed, ending in a conspicuous nail, and with the edges serrated; tarsi much compressed, the scales largest anteriorly; and the tail feathers 18 in the North American species. In the genus *mergus* (Linn.) the bill is longer than the head, and mostly red, with the serrations conical, acute, and recurved; the tarsi about $\frac{3}{4}$ of the middle toe; tail about $\frac{1}{2}$ the length of the wings; and head with a depressed crest. The red-breasted merganser (*M. serrator*, Linn.), sometimes called sheldrake in this country, is about 2 feet long, with an extent of wings of 33 inches, the bill $2\frac{1}{4}$ inches, and a weight of $2\frac{1}{2}$ lbs. In the male, the head and upper neck are dark green, the throat reddish brown with black streaks, sides finely barred with transverse black lines, feathers in front of wing white with black margins, white of wing crossed by 2 black bars, and under parts reddish white; head with conspicuous pointed crest; nostrils posterior. In the female, the upper parts are ash-colored, the lower reddish white, compressed crest chestnut brown, black at base of secondaries exposed; outer tertials white, edged with black. This bird is distributed over the whole of North America and Europe, fishing chiefly in fresh water; it breeds in the middle and eastern states, and as far north as Labrador, beginning to build, according to latitude, from the first of March to the middle of May, among the rank grasses near fresh water; the nest is carefully made of dried weeds and mosses, and lined with down from

the breast of the female; the eggs are from 6 to 10, $2\frac{1}{4}$ by $1\frac{1}{4}$ inches, in shape like those of the domestic fowl, and of a uniform pale yellowish cream color; the young betake themselves at once to the water, swimming and diving with great expertness. It is a very shy bird, and difficult to procure; the flight is rapid and well sustained; the habits are gluttonous; the food consists of fish, and its flesh is tough and fishy.—In the genus *lophodytes* (Reich.) the bill is shorter than the head, black, with oblique, low, short serrations, and the point truncated and not recurved nor acute; tail more than half the wings, tarsi half the middle toe, and head with an erect vertical crest. The only species is the hooded merganser (*L. cucullatus*, Reich.), which is about 18 inches long, with an extent of wings of 26 and the bill 2 inches, and a weight of about $1\frac{1}{2}$ lb. In the male, the head, neck, and back are black, with the under parts and centre of crest white; sides chestnut brown, barred with black; 2 black crescents on the white in front of the wing; lesser coverts gray; speculum of wing white, with a basal and median black bar; tertials black, with central white streaks; crest semicircular. In the female, the crest is shorter and more pointed; the head and neck reddish brown; no pure black on the back nor bars on the sides; white on the wings less, and the size much smaller. This, with the exception of the European white merganser (*mergellus albellus*, Selby; see SMRW), is the handsomest of the family. The habits are those of the other mergansers; it is distributed over the whole of North America. The eggs are like those of the preceding species, except that they are smaller; the flesh has a fishy taste and odor.—There is a small merganser in South America, for which was established the genus *merganetta* (Gould), which seems to mark the transition from the ducks to the mergansers. The bill is as long as the head, straight, compressed, elevated at the base; the shoulder of the wing in both sexes is armed with a strong sharp spur; the tail is lengthened, rounded, of rigid and pointed feathers. The only species mentioned by Gray is the *M. armata* (Gould), found inhabiting the rapid rivers of the Andes, swimming and diving against the mountain torrents with the utmost ease; so at home is it on the water, and so rarely disturbed, that it seldom makes use of its wings except for short flights; they are generally seen in pairs.—The affinity of the mergansers with the ducks is further shown by the occurrence of hybrids; there is in the cabinet of the Boston society of natural history a wild hybrid between the *L. cucullatus* and the golden-eyed duck (*clangula americana*).

MERIAN. I. **MARTHARA**, the elder, a Swiss designer and engraver, born in Basel in 1593, died in Schwalbach in 1651. He executed many plates of views in Germany, France, and Switzerland, but is best known by a series representing the environs of Heidelberg, Stuttgart, and other cities, from his own designs, published in Frankfort. Among his pupils was

the well known engraver, Wenzel Hollar. In the latter part of his life he removed to Frankfort-on-the-Main, where he established a book and print business. II. **MARTHARA**, the younger, son of the preceding, born in Basel in 1621, died in Frankfort in 1687. He studied painting under Vandyke and Rubens, and attained a considerable reputation for his portraits, particularly the equestrian ones. Among his best works of this class were the portraits of the emperor Leopold I. and other German princes, painted after the manner of Vandyke, and that of Count Serini on horseback. He also executed some historical pictures of merit, including a "Martyrdom of St. Lawrence" in the cathedral of Bamberg. III. **MARIA SIBYLLA**, sister of the preceding, born in Frankfort, April 12, 1647, died in Amsterdam, Jan. 18, 1717. She drew from nature flowers, caterpillars, butterflies and similar objects, which she executed in miniature with wonderful truthfulness. In 1663 she was married to Johann Andreas Graff, with whom she took up her residence in Nuremberg, retaining however her own name. She projected an entomological work, to be illustrated from her own designs, which was published in Dutch in 1679-'83, under the title of "The Origin of Caterpillars, their Nourishment and Changes" (2 vols. 4to., Nuremberg). A Latin translation of it appeared in Amsterdam in 1717, and in 1780 a new edition enlarged by her daughters and herself was published there in French under the title of *Histoire générale des insectes de l'Europe*. In 1684 she settled with her husband in Holland, and in 1699 made a voyage to Surinam, where during a residence of 2 years she prepared the materials for her *Dissertatio de Generatione et Metamorphosis Insectorum Surinamensium* (Amsterdam, 1705), of which a new edition with additional plates was published soon after her death under the supervision of her daughters. Her two works were republished together in 1768-'71 under the title of *Histoire des insectes de l'Europe et de l'Amérique* (fol., Paris).

MERIDA, the capital of Yucatan, in lat. $20^{\circ} 50'$ N. and long. $89^{\circ} 40'$ W.; pop. about 40,000, chiefly Indians and half breeds. It is built on an arid plain, on the site of a native city, about 25 feet above the sea level, and 25 m. from the gulf of Mexico. It is an ancient-looking place, and has wide and regular streets meeting in a large square in the centre, where the bishop's palace and the government house are situated. There is a cathedral, 14 churches, and the ruins of the monastery of San Francisco, which occupy about 5 acres of ground, and are enclosed by walls 40 feet high and 8 feet thick. The legislature meets in a convent once belonging to the Jesuits, most of which is in a ruinous condition. The college of Merida has a president and two or three professors, but its range of studies is very limited. Merida has a considerable trade, and there is an excellent road to the port of Sisal on the N. W. side of the peninsula. The climate, though dry and not

liable to sudden changes, is not very healthy. The town was founded by the Spaniards in 1542.

MERIDEN, a township and village of New Haven co., Conn., on the New Haven, Hartford, and Springfield railroad, 18 m. N. E. from New Haven; pop. of the township in 1860, 7,800. The village is handsomely situated on an elevation about $\frac{1}{2}$ m. from the railroad, and contains a bank, an academy, and several extensive manufactories. West Meriden, $\frac{1}{2}$ m. W., on the railroad and on the Quinepiack river, contains the state reform school, a high school, a newspaper office, and several manufactories and shops. In 1860 there were in the township 8 churches (1 Baptist, 3 Congregational, 1 Episcopal, 1 Methodist, 1 Roman Catholic, and 1 Universalist). Among the leading manufactures are tin and britannia ware, ivory combs, table cutlery, hardware, and machinery.

MERIDIAN. See LONGITUDE.

MÉRIMÉE, PROSPER, a French author, born in Paris, Sept. 28, 1803. He is the son of a painter, studied law, and was received as advocate, but did not practise his profession. After the revolution of 1830 he became secretary of the count d'Argout, and successively officiated as secretary in the ministries of commerce and marine. Subsequently he succeeded M. Vitet as inspector of ancient historical monuments of France, which furnished him with the materials for a number of valuable archæological works. In 1844 he was elected to the French academy, as successor of Charles Nodier. A paper written on behalf of his friend Libri, who had been accused of purloining from public libraries, subjected him to a brief imprisonment. While in Spain he became acquainted with the family of the present empress of France, and in 1853 he was made a senator. He has contributed to the romantic literature and drama of France the *Théâtre de Clara Gasul*, *comédienne Espagnole* (1825; new ed. 1846), a professed translation from the Spanish, and *La Guzla* (1827), a professed collection of Illyrian songs, both of which were original productions. His reputation has since been ably sustained by a series of novels, as *La double méprise*, *Colomba*, *Carmen*, &c. He has also written valuable historical novels, as *La Jacquerie*, &c., and a number of historical works. Among the latter are his *Histoire de Don Pèdre I., roi de Castille* (Paris, 1848; German translation, Leipsic, 1852), and *Épisode de l'histoire de Russie: les fauz Démétrius* (1854). His *Mélanges historiques et littéraires* and his *Marino Vreto, contes et poèmes de la Grèce moderne*, both appeared in 1855.

MERINO, GERONIMO, better known as "the priest Merino," a Spanish guerilla leader, born in Villaobiado, Old Castile, about 1770, died in 1847. He was educated at the theological college of Lerma, and, after spending 4 years in agricultural labor on the farm of his parents, he officiated in the parish church of his native village until 1808, when he came forward as the leader of a guerilla band against the French, displaying much courage and ferocity. In 1811

he avenged the execution of 4 members of the provincial junta of Burgos by putting to death 110 French prisoners. His cruelty caused him to be shunned even by his own relatives, but his fanatical allegiance to the cause of Don Carlos brought him into favor with that prince, and in Nov. 1833, he stood at the head of 20,000 volunteers between Burgos and Aranda when Gen. Quesada compelled him to take to flight. However, he continued to wage a guerilla war against the opponents of Don Carlos until 1838, when he was hopelessly defeated. He afterward accompanied the pretender to France, where he died.—Another Spanish priest, named MARTINO MERINO, a fanatical liberal, made an attempt upon Queen Isabel's life, on her return from the church, Feb. 2, 1852, inflicting a slight wound upon her, and was garroted 5 days afterward.

MERINO SHEEP. See SHEEP.

MERINTHUS. See CERINTHUS.

MERIONETHSHIRE, a maritime county of N. Wales, bordering on Cardigan bay; area, 602 sq. m.; pop. in 1851, 38,848. The surface is almost entirely rocky and mountainous, several of its summits attaining a height of 2,500 or 3,000 feet above the level of the sea. The most celebrated elevation is Cader Idris, whose summit is crowned with immense columns of crystalline basalt, similar to those forming the Giant's Causeway in Ireland. The principal rivers are the Dee, Maw, and Dovy. The most considerable lake is Bala, which is 12 m. in circumference. The minerals are gold, silver, lead, copper, limestone, and slate. At the slate quarries of Festiniog 8,000 persons obtain constant employment. Agriculture is generally in a backward state. The county returns one member to parliament. Capitals, Dolgelly and Bala.

MERIVALE. I. JOHN HERMAN, an English author, born in Exeter in 1779, died in April, 1844. He studied at St. John's college, Cambridge, but took no degree, on account of his being a Presbyterian, although afterward he joined the established church. He was called to the bar in 1805, practised for several years in the court of chancery, and officiated as commissioner of bankruptcy from 1831 till his death. He published several volumes of chancery reports, and contributed to the Rev. Robert Bland's "Collections from the Greek Anthology," of which he prepared a 2d edition in 1833. He published a poem, "Orlando in Roncesvalles," most of which is a free and abridged version of the *Morgante Maggiore*. A collection of his "Poems, Original and Translated," comprising the greater part of his earlier pieces, appeared in 1841, and was followed shortly before his death by translations of the "Minor Poems of Schiller." II. HERMAN, son of the preceding, published in 1841 "Lectures on Colonization and Colonies." III. Rev. CHARLES, B.D., is known as a historical writer by his great work still in progress, entitled "The Romans under the Emperors" (vols. i. to vi., 1850-'59), an abridgment of the first part of which was

published under the name of the "Fall of the Roman Republic" (1858).

MERIWETHER, a W. co. of Ga., bordered on the E. by the Flint river, and drained by a number of creeks; area, 525 sq. m.; pop. in 1859, 15,023, of whom 8,877 were slaves. There are a number of medicinal springs, for which the county is noted. The Warm Springs discharge 1,400 gallons per minute at a temperature of 90°. The productions in 1850 were 594,601 bushels of Indian corn, 116,791 of sweet potatoes, 98,050 of oats, 8,984 lbs. of rice, and 12,862 bales of cotton. There were 9 grist mills, 5 saw mills, 8 tanneries, 21 churches, and 860 pupils attending public schools. Capital, Greenville.

MERIWETHER, DAVID, an American soldier, born in Virginia in 1755, died near Athens, Ga., at an advanced age. During the revolution he became a lieutenant in the continental army, and did active service in New Jersey and elsewhere. He was present at the siege of Savannah, and was there taken prisoner, but was subsequently released on parole. In 1785 he removed to Georgia, and settled in Wilkes co., which he several times represented in the state legislature. In 1800 he was elected a representative to congress, and was a witness and participant in the struggle between Jefferson and Burr, being a warm supporter of the former. Associated with Gen. Jackson and Gov. McMinn of Tennessee, he concluded a treaty with the Cherokees, by which a large territory W. of the Appalachian river was ceded to the United States for the use of Georgia. He also made treaties with the Creeks and other tribes of Indians.

MERLE D'AUBIGNÉ. See **AUBIGNÉ**.

MERLIN, a European falcon, of the genus *hypotriorchis* (Boie), which differs from the genus *falco* (Linn.) chiefly in the more lengthened and slender tarsi, and long slender toes. This bird (*H. asalon*, Gmel.) is about a foot long, with an extent of wings of 29 inches, the male being a little smaller; it is the smallest of the British falcons, of pleasing colors, compact and graceful in form, with large head and short strong bill, the closed wings about 1½ inches shorter than the tail. In the male, the upper parts are deep grayish blue, each feather with a black central line, the tail barred with black, and the lower parts light reddish yellow with oblong blackish brown spots; in the female, the upper parts are grayish brown with darker shafts, the tail barred with pale reddish, and the lower parts yellowish white with large longitudinal markings; in both sexes the bill is pale blue at the base, and bluish black toward the end. From its courage and docility it was formerly trained to pursue larks and the smaller game birds. It is found all over Europe and western Asia; it very much resembles the American pigeon hawk (*H. columbarius*, Boie).

MERLIN, the name of two ancient British seers and sorcerers, who lived in the 5th and 6th centuries A. D. I. **MERLIN AMBROSIVS**, a native of Wales, is represented to have been the

son of a demon by a Cambrian princess. When a mere youth he recommended himself to the notice of King Vortigern by the display of supernatural powers; and he subsequently became the counsellor of that monarch, and of his successors Ambrosius, Uterpendragon, and Arthur. This is the Merlin to whom allusion is made by Spenser in his "Faery Queen," and by other old poets. He is also the subject of the metrical romance entitled "Merlin," of which Mr. Ellis has given an analysis in his "Early English Romances." A book of prophecies attributed to him was printed in French in 1498, in English in 1529, and in Latin in 1554. The principal account of him is given by Geoffrey of Monmouth, in his *Historia Britonum*. "The Life of Merlin Ambrosius, his Prophecies and Predictions interpreted, and their Truth made good by our English Annals," by T. Heywood, appeared in London in 1641. II. **MERLIN CALEDONIUS SYLVESTRIS**, or **THE WILD**, was a native of Strathclyde, in the S. W. of Scotland. He was contemporary with St. Kentigern, bishop of Glasgow, in the latter part of the 6th century. According to Fordun, having slain his nephew, he fled to the woods, and there led the life of a savage till his death. A band of peasants pursuing him, he sprang from a rock into the Tweed, in order to escape them, and was impaled on a stake that chanced to be in the bed of the river. The grave of this Merlin is still pointed out at Drummelzier, a village in Peeblesshire. A metrical life of him, incorrectly ascribed to Geoffrey of Monmouth, was printed for the Roxburgh club (London, 1830). The works attributed to him were published at Edinburgh in 1615; but as the rhapsodies and prophecies of the Cambrian and Caledonian Merlins are commonly confounded, being sometimes ascribed to one and sometimes to the other, it is now almost impossible to distinguish between them.

MERMAN AND **MERMAID**, fabulous beings dwelling in the sea, having the head and body of a man or woman, and the tail of a fish. The fiction may be derived from that of the tritons and nereids or sea nymphs of antiquity. Pliny, Ælian, and Pausanias give particular accounts of their being seen by sailors and others, especially in the seas around the island of Tairu-bane, and on the neighboring coast. Julius Caesar Scaliger, in his commentary on Aristotle (*de Animalibus*), maintains their existence. According to Alexander ab Alexandro, Theodore Gaza once saw a mermaid cast on shore in the Morea after a heavy storm. It had a human and charming countenance, but a scaly body and tail, was terrified and burst into tears on finding itself surrounded by spectators, and at the first opportunity scrambled back to the sea, plunged joyously in, and disappeared. In Alexander's own time the appearance of a merman in Epirus was a matter of public record. Rondani (1554) gave a picture of a singular merman seen in Poland, which was clothed by nature with the garb of a bishop. The most formidable animal of this kind is the devil-merman, *monstrum*

merium demoniforme, captured on the shore of Illyria, seen alive at Antwerp, and described by Aldrovandus. In the reign of Roger, king of Sicily, a young man bathing on shore met a maiden of great beauty, who remained for a time with him, but never spoke, and finally returned to the sea. The Bretons believe in mermaids which sing and comb their golden hair, and draw down to their palaces of gold and crystal at the bottom of the sea those who venture imprudently into the water. The merrows of Irish legends are mermaids. Capt. Whitbourne minutely describes a mermaid seen by him in 1610 in the harbor of St. John's, Newfoundland. Monsters of similar appearance have since been occasionally described; but it is affirmed by Sir Humphry Davy that a human head, human hands, and human mammae are wholly incompatible in the same creature with a fish's tail. Tennyson and other poets have availed themselves of the fiction.

MEROË, an ancient kingdom of Ethiopia in Africa, comprising the peninsula formed by the junction of the Nile and its tributaries, the Atbara and Bahr-el-Azrek, between lat. 18° and 18° N., and included in modern times in Nubia and Sennaar. By the ancients this peninsula was termed an island, and at certain seasons it becomes one by the overflowing of the rivers. It has on the E. the Abyssinian mountains, and on the W. the desert of Bahionda. Its length from N. E. to S. W. is about 375 m., and its breadth about 200; and it consists of extensive plains, which formerly were fertile and well cultivated, but are now for the most part desert. This country was very famous in antiquity. It produced gold, iron, copper, and salt; and partly from its natural riches, and partly from its situation between Ethiopia and the Red sea, it was from the earliest times the seat of a great commerce, carried on by caravans from all parts of northern Africa, which made its chief city their central rendezvous. Meroë, the capital of the kingdom, was a large and rich city on the Nile, about 90 m. N. of the modern Khartoom, between lat. 16° and 17° N. Here have been discovered the ruins of temples in the Egyptian style, and about 80 pyramids, the largest of which is 160 feet high. It was for a long time a favorite theory of historians and scholars that Egypt received its civilization and arts from Meroë; but these ruins indicate by their style and execution that Meroë was indebted to Egypt for its architecture and other arts. The political system of the kingdom was peculiar. It was ruled by priests, who elected the sovereigns from among themselves, and kept the royal power restricted within narrow bounds. They got rid of a king when they pleased by sending to him a messenger charged to tell him that the gods had decreed that it was time for him to die. For ages this intimation was implicitly obeyed, and the monarchs thus warned put themselves to death. It was a remarkable feature that the sceptre was often held by female sovereigns, the surviving widows of deceased

kings. The history of Meroë is very obscure. It has been conjectured that the kingdom owed, if not its origin, at least its peculiar polity and civilization, to the Egyptian soldiers who, according to Herodotus, emigrated from their country and went up the Nile to the number of 240,000 in the reign of Psammetichus (658-614 B. C.), because their privileges had been violated by that monarch. During the Persian occupation of Egypt, Meroë was an independent and important state. An attempt to subdue it made by Cambyses at the head of a large army totally failed. The theocratic government continued till the 3d century B. C., when Ergamenes, a native Ethiopian who had received a Greek education, became king. His mind, enlightened by Greek philosophy, was not subject to the superstitions that had enslaved his predecessors; and when the priests directed him to commit suicide he rebelled against the decree, and caused his army to massacre the priests. After this event little is known of the history of Meroë.

MEROPIS. See Cos.

MEROVINGIANS, the name of the first Frankish dynasty in Gaul or France. It was so called from Meroveus, king of the Riparian Franks (448-'58), who aided in the defeat of Attila in 451. He was succeeded by Childeric I. (458-'81), whose son Clovis, the conqueror of Gaul, and the first Christian monarch of the Franks, left his possessions in 511 to his 4 sons Thierry or Theodoric, Chlodomir, Childebert, and Clotaire, the first receiving the east (Austrasia), the 2d the south west (with Orleans), the 3d the centre (with Paris), and the 4th the north-east (with Soissons). The line of Thierry became extinct with his grandson Theodebald, son of Theodebert. The sons of Chlodomir were murdered, and Childebert left no male issue. Thus Clotaire, the youngest son of Clovis, reunited the empire of the Franks (558-'61). On his death it was again divided by his 4 sons, Charibert reigning in Paris, Gontran or Guntram in Orleans (to which Burgundy, a new conquest, was attached), Siegbert in Austrasia, and Chilperic in Soissons. This period was distracted by internecine wars, during which the two princesses Brunehaut and Fredegonda, the wives of Siegbert and Chilperic, were the most conspicuous characters. Siegbert was assassinated, and his son Childebert, who also inherited the possessions of Gontran, was succeeded by two sons, Theodebert and Theodoric, who died without legitimate male issue. Clotaire II., the son of Chilperic and Fredegonda, reunited the whole kingdom. It was again divided in 628 by his sons Dagobert and Charibert, the former of whom was the founder of a line of kings known as *fainéants* (lazy), their mayors of the palace being the real rulers of France. They were as follows: Siegbert II., king of Austrasia, 638-'56; Clovis II., of Neustria (the western kingdom) and Burgundy, 638-'56; Clotaire III., sole king, 656—of Neustria and Burgundy, 660-'70; Childeric II., of Austrasia, 660-'70—sole king 670-'73; Thi-

erry or Theodorio III., of Neustria and Burgundy, 670-'91; Dagobert II., of Austrasia, 674-'9; Clovis III., of Neustria and Burgundy (like all the succeeding), 691-'5; Childebert III., 695-711; Dagobert III., 711-'15; Chilperic II., 715-'20; Thierry IV., 720-'37; Childeric III. 742-'52—deposed by Pepin the Short, founder of the Carolingian dynasty.

MERRICK, JAMES, an English poet, born in Reading in 1720, died there in 1769. He was educated at Trinity college, Oxford, of which he became fellow in 1744. When only 14 years old, he published "The Messiah, a Divine Essay." While at Oxford he was tutor to Frederic North, afterward prime minister. He took orders, but from delicate health was unable to perform his clerical duties. His most important works are: "Prayers for a Time of Earthquakes and Floods" (London, 1756); "The Psalms Translated or Paraphrased in English Verse" (Reading, 1766); "Annotations on the Psalms" (Reading, 1768). His poetical fable, "The Chameleon," is now the best known of his works.

MERRIMACK, a river of New England, formed by the junction of the Pemigewasset and Winnipiseogee rivers at Franklin, N. H. From this point the river runs S. 78 m. to Chelmsford, Mass., and thence E. 85 m. to the Atlantic ocean at Newburyport; total length 113 m. Its tributaries in New Hampshire are the Contoocook, the Soucook, the Suncook, the Piscataquog, the Souhegan, and the Nashua; in Massachusetts, the Concord, Spigot, Shawshine, and Powow. The principal tributaries are on the right side of the river. There are numerous falls in the Merrimack, and the river furnishes an immense water power, the employment of which in manufacturing has created the cities of Lowell and Lawrence, Mass., and Nashua and Manchester, N. H. The Merrimack is a noble river, with pure waters and beautiful and well peopled borders. Its width varies from 50 to 150 rods. The name is of Indian origin, and is derived from a word signifying a sturgeon.

MERRITT, TIMOTHY, an American clergyman, born in Barkhamstead, Conn., in Oct. 1775, died in Lynn, Mass., in 1845. He became a minister of the Methodist Episcopal church in 1796. He edited for some time "Zion's Herald" at Boston, and the "Christian Advocate and Journal" at New York, and published "The Christian's Manual," "Convert's Guide and Preacher's Assistant," "Universal Salvation," and "Memoir of Miss H. S. Bunting."

MERSEBURG, a district of Prussian Saxony; area, 8,994 sq. m.; pop. in 1852, 756,346. The surface toward the E. is mostly level, but toward the W. is rather mountainous. The soil is generally good. The minerals are of great value, and include silver, lead, copper, iron, coal, and lignite. The principal rivers are the Elbe, Mulde, and Saale. The capital, Merseburg, is on the left bank of the Saale, 15 m. W. from Leipsic; pop. 12,500. It is fortified, and

was formerly one of the most important towns of Germany, but has much declined.

MERSEY, a river of England, formed by the union of several small streams, which have their sources in the hills near the borders of Yorkshire, Cheshire, and Derbyshire. The two principal of these, the Tame and the Goyt, after receiving the tributary waters of all the rest, unite at Stockport. Here the river takes the name of Mersey, and flowing W. divides Cheshire from Lancashire, and falls into the Irish sea below Liverpool. The chief affluents of the Mersey are the Irwell and Weaver. At Runcorn, about 17 m. from its mouth, it expands into a large estuary, which varies in breadth from 2 to 8 m., and contracts at its mouth to about $\frac{1}{2}$ m. The course of this river is mostly through a level country, but its scenery is occasionally very picturesque. The principal towns on its bank are: Stretford, Warrington, Hale, Garston, and Liverpool, on the right bank; and Stockport, Runcorn, Ince, and Birkenhead on the left. Its entire length is from 55 to 60 m., for the greater part of which it is navigable.

MERTHYR TYDVIL, a parliamentary borough of Glamorganshire, South Wales, 21 m. N. by W. from Cardiff, with which it is connected by the Cardiff canal and the Taff Vale railway, and 171 m. W. by N. from London; pop. in 1851, including the adjoining town of Dowlais, 63,080. It is in the midst of the great mineral region of South Wales, and has attained its present importance during the last 100 years, previous to which it was a mere village. It is irregularly and poorly built, and deficient in cleanliness, but gradually improving. In 1851 it contained 84 places of worship, of which 20 belonged to the Independents, 19 to the Baptists, 10 each to the Church of England, Wesleyan Methodists, and Welsh Calvinistic Methodists, and 6 to the Mormons. There were 16 public schools with 2,544 pupils, and 43 private schools with 1,185 pupils. It has many extensive iron works, one of which, at Dowlais when in full work, employs 6,000 men; and the annual production of iron is about 200,000 tons.

MERU. See DEMON.

MÉRY, JOSEPH, a French poet and novelist, born in Aigalades, near Marseilles, Jan. 21, 1798. He made his first appearance as an author in 1820 by the publication of a satire in verse against the abbé Elicagaray, for which he was sentenced to 15 months' imprisonment. Subsequently he became attached to the *Phoenix*, a liberal sheet published in Marseilles, which he abandoned to found a journal of his own, the *Méditerranée*. Both were soon after merged in the *Sémaphore*. In 1824 he established himself in Paris, and became the intimate associate of Armand Carrel, Victor Hugo, and particularly of Auguste Barthélemy, with whom he entered into a sort of literary partnership, founded upon common animosity toward the existing government, and which for several years was the fruitful source of satirical and political poems. The first offspring of their united

talents was the *Réponse de Sidi Mahmoud*, a witty satirical poem, succeeded in 1826 by the *Villéliade*, an attack on the ministry of Villèle, which brought them in 25,000 francs, and made a decided impression. *Rome à Paris* and *La Peyronnéide*, published in the following year, were equally effective, and aided in the overthrow of the unpopular minister. They next wrote in a higher strain their poem, *Napoléon en Égypte*, a subject which the strong Bonapartist sympathies of Méry enabled him to treat with peculiar vigor. The revolution of July, 1830, was commemorated by them in a poem, *L'insurrection*, and a hymn, *La tricolore*, set to music by Halévy. They subsequently founded the *Némésis*, which for upward of a year was the weekly receptacle of their stinging assaults upon the government of Louis Philippe. Upon the discontinuance of the paper Méry went to Italy, whither he had been invited by Queen Hortense and other members of the Bonaparte family. Scarcely known hitherto except as a poet, he now commenced the career of a romance writer, and produced in rapid succession a number of works founded partly on his observations of Italian life. A trip to England furnished him with the materials for his *Nuits de Londres* (1840), and he subsequently published in the *Presse* newspaper of Paris *Héva*, *La guerre de Nizam*, and *La Floride*, describing India and Africa, countries which he had never seen. With equal confidence he sketched China and the Chinese in his *Anglais et Chinois* (1848). He is the author of numerous prose pieces originally published as *feuilletons*, and of several dramas, the latter being the least successful of his performances. As a romance writer he is distinguished by quickness of invention and facility of composition, and by a warmly colored but capricious and affected style. His verses are neatly written, and have much melody of rhythm. His devotion to the Bonaparte family has been testified by the production of several poems written since the *coup d'état* of 1851, in praise of the emperor Napoleon III.

MESILLA, a town and valley N. of El Paso, on the W. bank of the Rio Grande of New Mexico. It obtained notoriety from a dispute between the United States and Mexico in the settlement of the boundary under the treaty of Guadalupe Hidalgo, made in 1848. It was subsequently purchased by the United States by the "Gadsden treaty" of 1858, including the territory lying to the W. as far as the Colorado river and gulf of California. Mesilla is the diminutive of the Spanish *mesa*, table; as here applied, it means a small plateau, or table-land, on the bottom land of the Rio Grande, to distinguish it from the great table-land which is more elevated, and which extends for many hundred miles on both sides of the river. The Mesilla valley is a rich alluvium, while the great plateau is not susceptible of cultivation, although portions of it consist of grazing lands. The valley, of which the Mesilla is a part, is about 80 m. in length, with a breadth of from

1 to 3 or 4 m., and is simply the bottom land of the Rio Grande. Although the soil is rich, it cannot be cultivated without artificial irrigation; but the water of the Rio Grande is insufficient to irrigate the whole of the bottom lands on both its sides. The town was settled in 1850, and now has a population of about 2,500.

MESMER, FRIEDRICH ANTON, a German physician, the first promoter of animal magnetism, or, as it has been called, "mesmerism," born in Meersburg, Baden, on the lake of Constance, in 1734, died there, March 5, 1815. He studied physic in Vienna, and took his degree of M.D. there in 1766, presenting on that occasion a thesis *De Planetarum Influxu in Corpus Humanum*, in which he held that the universe is pervaded by a subtle element exercising an extraordinary influence on the human body, and identical with the magnetic element. The means by which he brought his theory into notice and practical operation, as well as the leading features of his life, will be found detailed at length under the head of ANIMAL MAGNETISM.

MESMERISM. See ANIMAL MAGNETISM.

MESOPOTAMIA (Gr., between the rivers, viz., Euphrates and Tigris; Heb. *Aram Naharaim*, Syria between the two rivers; now *Al Jezira*, the island), an ancient country of western Asia, bounded, according to the common acceptation of the name, N. by Armenia, from which it was separated by the Masius range, a branch of the Taurus; E. by the Tigris, separating it from Assyria; S. by Babylonia; and W. by the Euphrates, separating it from Syria. The Greek name was first used in the time of the Seleucidæ, being mentioned neither by Herodotus, in whose time the country formed a part of the Persian satrapy of Babylonia, nor by Xenophon, who extends the limits of Syria across the Euphrates. Polybius and Pliny use the name in a wide sense. Excepting the Masius range and its prolongation parallel to the upper Tigris, Mesopotamia formed a vast and mostly very fertile plain, well watered by rivers and canals, the chief affluent of the two great rivers being the Chaboras, and the principal productions of the country grain, fruits, spices, timber, cattle, naphtha, and jet. The southernmost part of the plain, however, resembled the adjoining region of the Syrio-Arabian desert, and was inhabited by numerous wild animals, including lions, ostriches, and wild asses. Among the cities of Mesopotamia were: Apamea on the Euphrates, opposite Zeugma in Syria; Edessa (now Orfa), the capital of the north-western province of Osroene; Carræ or Carrhæ, the Haran of Abraham; Circesium, the scriptural Carchemish, near the mouth of the Chaboras; Nisibis, the scriptural Zoba, in the north-eastern province of Mygdonia; Dura, in the desert. Mesopotamia was inhabited in the earliest times by numerous tribes of various race, none of whom succeeded in establishing an important state. In historical times it was in turns a part of the Assyrian, Babylonian,

Persian, Macedonian, Syrian, Parthian, and Neo-Persian monarchies, until it was conquered by the Arabs. It was subsequently invaded by the Seljooks, conquered in part by the crusaders, and finally became a province of the Ottoman empire.

MESSALA, or **MESSALLA** (**MARCUS VALERIUS MESSALA CORVINUS**), a Roman general, orator, and author, born, according to Eusebius, in 59, but according to Scaliger about 70 B. C., died about the beginning of the Christian era. He completed his studies at Athens, and on the outbreak of the 2d civil war joined Brutus and Cassius in the East, and was appointed to the 8d rank in the republican army. At the first battle of Philippi he stormed the camp of Octavius, and almost took him prisoner. After the overthrow of his party he surrendered to Antony, to whom he attached himself until, perceiving the ruin of that triumvir inevitable, he withdrew from his service, and entered that of his rival, for whom he fought in Sicily, against the Salassi in the Alps, and at Actium. In 81 B. C. he was appointed to succeed Antony as consul, and subsequently obtained the proconsulship of Aquitania, for the reduction of which province a triumph was decreed him. He was selected by the senate to greet Augustus with the title of *pater patriæ*, and the exordium of his oration has been preserved by Suetonius. Soon after this Messala resigned all his official dignities except the augurship, a special appointment of his patron, and retired to private life. Only fragments of his orations remain (Paris, 1842); his other writings are only known by their titles.

MESSALINA, or **MESSALLINA**, the name of two Roman empresses, who lived in the 1st century of the Christian era. I. **VALERIA**, daughter of M. Valerius Messala Barbatulus, and 8d wife of Claudius I., to whom she was married before his accession to the empire. She was a woman of very profligate character, and as cruel as profligate. Many members of the most illustrious families of Rome were sacrificed to her fears, her jealousy, or her hatred. Among her noblest victims were the two Julias, one the daughter of Germanicus, the other of Drusus, son of Tiberius, who had excited her jealousy or envy; C. Appian Silanus, who had wounded her vanity by rejecting her advances; and Justus Catonius, whose offence was privy to her guilt. For a long time Claudius was blind to her infidelity; but when, during his absence at Ostia, she contracted a public marriage with Caius Silius, a handsome youth for whom she had conceived a violent passion, he caused her to be put to death. The sentence was executed in A. D. 48, by a prætorian tribune, in the gardens of Lucullus. She was the mother of two children by Claudius, Britannicus and Octavia. II. **STATILIA**, the 8d wife of the emperor Nero, and the granddaughter of Titus Statilius Taurus, who had been consul in A. D. 11. She was first married to Atticus Vestinus, but the tyrant caused her husband to be put to death, and

espoused her in 66. She survived Nero, and would have been wedded to Otho had he been successful in the war against Vitellius.

MESSANA. See **MESSINA**.

MESSENE, the capital of Messenia in Peloponnesus, founded by Epaminondas after his victory of Leuctra over the Lacedæmonians, and situated at the foot of the hill of Ithome, the fortress of which formed the acropolis of the new capital. The latter was surrounded by massive stone walls, flanked with towers, of which there are still considerable remains at the modern village of Mavromati. Messene with its acropolis was, next to Corinth, the strongest city of Peloponnesus. It was supplied with water from a fountain called Clepsydra, the spring of which still exists.

MESSENI, or **MESSENE**, the S. W. division of Peloponnesus in ancient Greece, bounded N. by Elis, from which it was separated by the river Neda, and Arcadia; E. by Laconia, the boundary line varying at various periods; and S. and W. by the sea, which on the S. forms the large gulf of Messenia, or, as it is now called, of Coron. It is a mountainous country, containing but two plains of any extent, the southern of which, traversed by the Pamisus, was called Macaria or the Blessed on account of its great fertility. The valleys among the mountains, too, were regarded as fertile, and the whole country was renowned for the mildness of its climate. Among the few towns of note were Pylos, a seaport, according to some the seat of Nestor, Cyparissia, Corone (now Coron), Methone (Modon), Abia, Dera, Stancylerns in the northern plain of the same name, and the later capital Messene, founded by Epaminondas, beside the mountain fortresses of Ithome and Ira, so celebrated in the history of the Messenian wars. The earliest inhabitants of Messenia were Leleges and Argives. Polycaon, son of Lelex, is said to have given the country its name from Messene his wife, daughter of the Argive Triopas. It was subsequently settled by Æolians. During the following period Messenia seems to have belonged partly to the kingdom of Pylos and partly to that of Lacedæmon. When the Dorians conquered Peloponnesus, it became the possession of Cresphontes, who destroyed the kingdom of Pylos. Of the kindred Ionian states, Sparta, the eastern neighbor, soon developed its aggressive policy, and after various collisions and mutual inroads the first Messenian war broke out in 743 B. C. It lasted 20 years, and ended with the fall of Ithome and the subjugation of Messenia, its gallant resistance under Aristodemus, who sacrificed his daughter to the freedom of his country, and finally killed himself on her tomb, being of no avail. Part of the inhabitants sought refuge in other countries. After 88 years of subjection, the Messenians rose under the lead of the heroic royal descendant Aristomenes, being supported by Argos, Arcadia, and other states of Peloponnesus, while their enemies received the support of Corinth, and after many defeats were unexpectedly annihilated.

the wisdom and inspiring songs of the Athenian Tyrtaeus. Thus Aristomenes, too, succumbed after a struggle of 17 years (668), and Ira fell. New emigrants now settled in Italy and Sicily, giving the name of Messana to the town of Zancle in that island. The remaining inhabitants were reduced by the conquerors to the condition of helots. Together with the other slaves of Sparta, they were induced by the great earthquake which devastated the capital of their oppressors in 464 to strike once more for freedom. This third Messenian war lasted 10 years, and was terminated by the capitulation of the defenders of Ithome, who were allowed a free departure from Peloponnesus. They settled at Naupactus, on the northern shore of the Corinthian gulf, a town recently conquered by Athens, now the declared rival of Sparta. When the former was finally crushed by the fatal issue of the Peloponnesian war, the Messenians of Naupactus were compelled to leave Greece. The noblest enemy of Sparta, the Theban Epaminondas, finally restored the independence of Messenia, convoking the refugees from the various lands of their exile, after the great battle of Leuctra (371), and giving the country a strongly fortified capital in Messene, a new town at the foot of the old stronghold Ithome (369). From this period the Messenians maintained their independence down to the time of the Roman conquest of Greece in 146.

MESSER, ASA, D.D., LL.D., an American clergyman, born in Methuen, Mass., in 1769, died in Providence, R. I., Oct. 11, 1886. He was graduated in 1790 at Brown university, where the next year he was chosen tutor, and in 1796 was elected professor of the learned languages, in 1799 professor of mathematics and natural philosophy, and in 1802 president of the university. He held this position for 24 years, when he resigned. He was licensed to preach by the 1st Baptist church in Providence in 1792, and ordained in 1801. He preached occasionally for congregations of different denominations, but was never settled as a pastor. The citizens of Providence for several years elected him to important civil offices. Three of his discourses and 5 orations have been published.

MESSIAH. See **JESUS CHRIST**.

MESSINA, a province of Sicily, including the N. E. extremity of the island, bounded N. by the Mediterranean, E. by the strait of Messina, which separates it from Calabria, S. by the province of Catania, and W. by that of Palermo; area, about 1,500 sq. m.; pop. in 1856, 384,664. It is traversed from E. to W. by the Neptunian mountain range, and by the Monteforte, San Antonio, and a number of other small streams. The mountains abound with wood. There are no large plains, but many valleys, which as well as the banks of the rivers are very fertile in wine, oil, and fruit of every sort, particularly oranges. The other principal products are hemp and flax. The most important mineral product is sulphur. On the S. a portion of the province skirts the base of Mt. Etna.

It is divided into 4 districts, 29 arrondissements, and 98 communes, and includes the Lipari islands. The chief towns, beside Messina, the capital, are Castro Reale, Melazzo, Patti, Randazzo, and Taormina.—**MESSINA** (anc. *Messana* or *Messene*), the capital of the above province, is situated on the N. E. corner of the island, on the strait of Faro or Messina, here about 4 m. wide, 120 m. E. by N. from Palermo, and 50 m. N. E. from Mt. Etna; pop. about 100,000. The approach from the sea is of remarkable beauty, the city rising from the shore in the form of an amphitheatre, and the dazzling whiteness of the houses presenting a picturesque contrast to the dark mountains in the background. The principal part of the city is built on the W. side of the harbor, paved with square blocks of lava, and contains several wide and handsome streets ornamented with statues and fountains. Among the public buildings are more than 50 churches, the most ancient of which is the cathedral, the arsenal, the naval arsenal, the viceroy's palace, the archbishop's palace, the senate house, the custom house, a large hospital, 2 theatres, a lazaretto, and numerous convents and nunneries. Messina is the seat of an archbishop and of a Greek *protopapas*, who is nominated by the pope and exercises authority throughout Sicily. It has a royal court of appeal and other courts of law, an exchange, and several banks and *monti di pietà*. The harbor is one of the finest in the world, and the port has been free since 1852. It is defended by several forts, extends about 4 m. in circuit, and can accommodate the largest fleet. The principal exports are oranges, lemons, currants, raisins, wine, brandy, olive oil, linseed, sumach, liquorice, rags, and corn. Nearly all the silk exported from Sicily is shipped from Messina. The imports are colonial produce, cotton and woollen fabrics, hides, and hardware. The exports from Messina to the United States amounted in 1857 to \$679,864, and in 1858 to \$524,698; they consisted of lemons, oranges, filberts, wine, brimstone, almonds, essences, &c. The imports from the United States decreased from \$42,830 in 1857 to \$18,230 in 1858, and included staves, rosin, rum, tobacco, &c. The principal manufactures of Messina are damasks and satins. Coral, tunny, and other fisheries are extensively carried on. Messina is defended by walls and bastions, a citadel, and many forts, and is considered a fortress of the highest importance, as commanding the strait of its name, and thus being the principal gate to Sicily from the mainland.—The origin and early history of the ancient city are involved in obscurity. It is believed to have been founded by colonists from Magna Græcia and Greece between 1000 and 800 B. C., to have made rapid strides in prosperity, and to have derived its name from a body of emigrants from Messene in Greece, the original name having been, according to Thucydides, Zancle, after the similar Greek word signifying a sickle (the form of the harbor). In 396 B. C., when the city was celebrated for its flourishing trade, a

Carthaginian army landed in Sicily and destroyed the city, which was the next year rebuilt by Dionysius of Syracuse, who expelled the invaders. About 280 B. C. it was seized by the mercenaries expelled from Syracuse on the death of Agathocles, who were called Mamertini, children of Mamers or Mara, and who subsequently, in order to maintain themselves in power, applied for assistance to the Romans; hence arose the first Punic war, in the course of which the city was taken by its allies, and thus became the earliest dependency of Rome beyond the Italian continent. Cicero calls it a very great and very rich city, and speaks highly of the advantages of its port and of its situation. In the civil war (48 B. C.) it was the station of a part of the fleet of Cæsar, and Sextus Pompey after his defeat by the fleet of Octavian under Agrippa made his escape from thence with only 17 ships. The famous wine of the neighborhood of Messina (*vinum Mamertinum*) was first brought into vogue by Julius Cæsar. During the middle ages Messina continued to be an important city. To avenge the massacres of Sicily it was besieged by Charles of Anjou, king of Naples, but relieved in 1282 by Peter of Aragon and Roger de Loria. In 1678 it submitted to Louis XIV., but he was compelled to withdraw his forces by the Dutch and Spanish fleet, and the citizens were severely punished. In 1698 it was nearly destroyed by an earthquake and an eruption of Mt. Etna, and in 1740 it was afflicted by the plague. Another earthquake in 1788 destroyed and depopulated almost the whole city, and it has since been rebuilt upon a better plan. A revolutionary outbreak took place there in 1848, but the insurgents were put down by the Neapolitans (Sept. 7). The possession of Messina during the war of that year enabled the king of Naples to reconquer the island. Every attempt at a popular movement was therefore punished with the utmost rigor, a strong garrison continually kept there, and the fortifications of the place strengthened. In 1860, however, the victorious advance of Garibaldi's army made all precautions vain, and after the victory at Melazzo (July 20) the revolutionary army entered the town, and an agreement was soon after entered into by Gen. Medici with Clary, the commander of the royal troops, according to which the citadel and 3 forts were to remain in the hands of the latter, and the town and 2 forts in the undisputed possession of the Sicilians.

MESTIZO, a Spanish-American term for the mixed offspring of Europeans and Indians. In Mexico mestizoes are very numerous. Their color is almost a pure white, with a skin of remarkable transparency. The chief indications of the mixture of Indian blood are a thin beard, small hands and feet, and an obliquity of the eyes. The women of this race are called *mestizas*, and the offspring of their marriages with whites differ but slightly from pure Europeans.

MÉSZÁROS, LÁZÁR, a Hungarian general, born in Baja, county of Bács, Feb. 20, 1796,

died at Eywood, Herefordshire, England, Nov. 16, 1858. He came of a poor but noble family, and being left an orphan at a tender age, was educated under the care of some relatives for an ecclesiastical career, and subsequently studied law at Pesth; but in 1813, on the outbreak of the new war against Napoleon, he entered the Hungarian army in the service of the emperor Francis. He fought with distinction in the last campaigns against Napoleon, and subsequently in Italy, and in 1845 attained the rank of colonel in a hussar regiment. He was in Italy in the spring of 1848, when during the retreat of Radetzky from Milan he received the first information of the important changes in Hungary, and was soon after offered the ministry of war in the cabinet of Batthyányi. He hesitated from modesty to accept it, but finally started for Pesth, where he soon learned the immense difficulties of his new position. Elected a member of the diet, he defended the moderate measures of the ministry, and was exposed to attacks on the part of the more revolutionary members, especially Perczel. Repairing personally to the scene of war in the south, he gave ample proofs of intrepidity, but failed in his attempts to storm the Rascian ramparts of Szent Tamás (September). The treachery of the Vienna cabinet and of the Austrian officers, who serving under him only checked his movements, threw him on the revolutionary side when Austria finally avowed the purpose of subjugating Hungary. In December he again took the field in the north, whither he was sent to check the advance of Schlick; but after an indecisive encounter at Szikszó (Dec. 28), his motley army suffered a total rout before Kaschau (Jan. 4, 1849). His well known patriotism and frankness in acknowledging his incapacity to lead an army saved him from all dishonorable imputations; and by his witty addresses in the national assembly at Debreczin he even secured a lasting popularity. When the difficulties with Görgey compelled Kossuth to appoint a new commander-in-chief, the title was given to Mézáros and the real command to his friend Dembinski, with whom Mézáros soon after shared in the defeat at Szőreg (Aug. 5) and Temesvár (Aug. 9), and a few days later in Turkish exile. Accompanying Kossuth to Widdin, Shumla, and Kutiak, he was allowed in May, 1851, to depart for England, where he was cordially received. Having lived for some time in France, he repaired to the island of Jersey after the *coup d'état* of Dec. 2, 1851, and in the summer of 1853 sailed to America. He enjoyed the quiet tranquillity of a life at Flushing, L. I., until he received the rights of American citizenship, when he started on a tour to Switzerland, where a number of his exiled friends resided; but he died a few days after his arrival in England, at the mansion of Lady Langdale, the mother-in-law of his countryman, Count Teleky. One of the most dignified representatives of his nation in exile, his sudden death was deeply regretted by his fellow patriots. He left various writings, published and unpublished.

METAL (Gr. *μεταλλον*). All simple substances are commonly classed as metals and metalloids. Those of the former division are distinguished by their brilliant peculiar lustre, called metallic, by their being good conductors of electricity and heat, and always appearing when their compounds are decomposed by the electric current at the cathode or negative pole—hence being all electro-positive or cations. The common metals may also for the most part be recognized by their high specific gravity, and many by the properties of malleability and ductility, by which they can be extended under the hammer and drawn out into wire. They are opaque, and even when converted into exceedingly thin leaves but rarely transmit light, and then very feebly and but a portion of the ray. The luminous rays, not being transmitted by reason of the opacity of the substance, are reflected from the polished surface which the metals readily take, and hence the lustre these possess. This is one of the most striking characteristics of the metals, and is readily developed even in their fine dust, when this is rubbed with an agate burnisher. It is most perfect in polished steel and the brilliant surface of mercury, as seen upon the backs of mirrors where the metal is protected from tarnishing. The reflected light with most of the metals is whitish with a shade peculiar to each metal; gold, however, is yellow, and copper and titanium red. A few possess a peculiar odor when rubbed, as copper and iron, and arsenic when oxidized and converted into vapor. Some also impart to the tongue a taste called metallic, which is more perceptible in their soluble compounds. The distinctive properties of the metals cannot be strictly defined; and the division of simple bodies into metals and metalloids is to some extent an arbitrary one. Several in fact possess properties according to which they might be referred to one or the other class. Thus arsenic is called a metal by some chemists, and by others is ranked with the metalloids. Phosphorus, though always classed as a metalloid, resembles arsenic in its chemical properties, and has a decided metallic lustre. So carbon in the state of graphite appears like a metal, and in strongly calcined charcoal is a good conductor of electricity; it is, however, always regarded as a metalloid. Tellurium, arsenic, antimony, and tungsten (to which group bismuth has recently been added) may be considered half metals, marking the transition between the two great classes of simple bodies.—The metals are usually reckoned as 48 in number, and exceed considerably the non-metallic bodies. Among them are many scarcely known except to one or two chemists, who have separated them from their rare native combinations; they consequently possess none but a scientific interest. Some of these, however, may hereafter become of importance, as aluminum now promises to, which a few years since was one of the rarest. The names of the metals and of their discoverers, so far as known, are given in the following table:

Name.	Date of discovery.	By whom discovered.
Gold.....	Known to the ancients.
Silver.....		
Iron.....		
Copper.....		
Mercury.....		
Lead.....		
Tin.....	1490	Described by Basil Valentine.
Antimony.....		
Bismuth.....	1529	Described by Agricola.
Zinc.....	16th century	First mentioned by Paracelsus.
Arsenic.....	1783	Brandt.
Cobalt.....		
Platinum.....	1785	Ulloa, a Spanish traveller in America.
Nickel.....	1751	Cronstedt.
Manganese.....	1774	Scheele and Gahn.
Tungsten.....	1781	D'Elhuyart.
Tellurium.....	1782	Müller.
Molybdenum.....	1782	Hielm.
Uranium.....	1789	Klaproth.
Titanium.....	1791	Gregor.
Chromium.....	1797	Vauquelin.
Tantalum.....	1802	Hatchett.
Palladium.....	1803	Wollaston.
Rhodium.....		
Iridium.....	1803-'4	Descotils and Smithson Tennant.
Osmium.....	1803	Smithson Tennant.
Cerium.....	1803	Hisinger and Berzelius.
Potassium.....	1808	Davy.
Sodium.....		
Barium.....		
Strontium.....		
Calcium.....	1817	Stromeyer.
Cadmium.....		
Lithium.....	1818	Davy.
Zirconium.....	1824	Berzelius.
Aluminum.....	1825	Wöhler.
Glucinum.....		
Yttrium.....	1829	Berzelius.
Thorium.....		
Magnesium.....	1829	Bussy.
Vanadium.....	1830	Selfström.
Lanthanum.....	1841	Mosander.
Didymium.....	Since 1840	Mosander.
Erbium.....		
Terbium.....	1844	Klaus.
Ruthenium.....		
Pelopium.....	1845	H. Rosa.
Niobium.....		

To this list of metals is now to be added a new one belonging to the group of niobium, tantalum, &c., discovered by Von Kobell in 1860, and termed by him dianium. It exists in an acid combination separated by Von Kobell from the minerals euxenite, ceschynite, samarskite, and a tantalite from Tammela. (*Bulletin der Akademie der Wissenschaften*, March 10, 1860.) The chemical equivalents of these elements are given in the article EQUIVALENTS, and the densities of the most important of them in the article GRAVITY, SPECIFIC. The arrangement of 13 of the principal metals according to their electro-chemical character is given in ELECTRO-DYNAMICS, vol. vii. p. 65; but it must be remembered that this order is not invariable under all circumstances. Their other individual properties are treated in the articles describing each metal under its own head. The properties of density, hardness, ductility, tenacity, fusibility, &c., are very variable among the different metals. Platinum (sp. grav. 21.5), iridium (23?), and gold (19.8) present the heaviest forms of matter; while the specific gravity of lithium is only 0.593, or but little more than half the density of water. Metals having the great-

est affinity for oxygen, as potassium (sp. grav. 0.865), sodium (0.972), calcium (1.578), &c., are distinguished by their low densities; and those which are least oxidizable by their great densities. The range of hardness is from that of titanium and manganese, which are harder than steel, to potassium and sodium, which at 60° are as soft as wax, and even to mercury, which is a liquid at ordinary temperatures. The ductility of metals, tested by drawing them into wire, is possessed by the following in the order in which they are named, the first in the highest degree: gold, silver, platinum, iron, nickel, copper, zinc, tin, lead, palladium, cadmium. But according to the strength of the wires, or the property of tenacity, the arrangement will be very different. This property differs indeed in the same metal according to its purity and the mode in which it has been prepared. The following weights were sustained by wires 0.787 of a line in diameter: iron, 549.250 lbs.; copper, 302.278; platinum, 274.320; silver, 187.137; gold, 150.753; zinc, 109.540; tin, 84.630; lead, 27.621. A number of the metals are brittle, and some may be rubbed to powder. The effects of heat upon the different metals are variously manifested. Gold, silver, and copper transmit it quickly, while the conducting power of iron, platinum, zinc, tin, and lead is comparatively feeble. When their temperature is raised from 32° to 212°, their linear expansion is as follows: of Malacca tin, $\frac{1}{18}$; hammered zinc, $\frac{1}{22}$; cast do., $\frac{1}{25}$; silver, $\frac{1}{24}$; lead, $\frac{1}{11}$; copper, $\frac{1}{13}$; gold, $\frac{1}{11}$; iron, $\frac{1}{12}$; palladium, $\frac{1}{10}$; platinum, $\frac{1}{10}$. All may be fused, but the temperatures required are very various. (See FUSIBILITY.) Platinum and a number of the rare metals are melted only by the intense heat of the compound blowpipe, sodium and potassium respectively at 190° and 186° F.; and mercury assumes the solid state only when the temperature is reduced 39° or more below zero. Arsenic volatilizes before it fuses, and many of the metals are rendered more or less volatile by higher temperatures than are required for their fusion. The combinations of metals with each other have been treated under ALLOYS; or, when mercury is one of the combining metals, under AMALGAM. All the metals may be made to combine directly or indirectly with oxygen. Some become oxidized by exposure to the air, a few absorb oxygen with the phenomenon of combustion when thrown upon water, and many burn vividly when heated and introduced into oxygen. The arrangement by Thénard of the metals into six groups (*Annales de chimie et de physique*, vol. lxii. p. 368) is founded on their different affinities for oxygen. They are: 1. Metals which decompose water even at 32° with lively effervescence, viz.: potassium, sodium, lithium, barium, strontium, calcium. The first three of these are called metallic bases of the alkalis; the last three the metallic bases of the alkaline earths. 2. Those which decompose water rapidly only at a heat approaching 212° or above this; as manga-

nese, magnesium, aluminum, glucinum, zirconium, cerium, thorium, yttrium, and lanthanum. 3. Those which in solid masses do not decompose water except at a red heat, or at ordinary temperatures, when a strong acid is added to the water; such are iron, nickel, cobalt, zinc, cadmium, tin, chromium, and probably vanadium. When in a finely divided state these metals absorb oxygen much more energetically. 4. Those which at a red heat decompose steam with rapidity, but do not decompose water acidulated with strong acids. The oxides of these metals act feebly as bases, and are in fact ranked among acids. These metals absorbing oxygen at a red heat, their oxides cannot be reduced to the metallic state by heat alone. They are tungsten, molybdenum, osmium, tantalum, titanium, arsenic, antimony, tellurium, and uranium. 5. Those which decompose water only at very high temperatures and in a feeble manner, and which differ from those of the 4th group by forming basic and not acid oxides; they are copper, lead, and bismuth. 6. Metals, the oxides of which are reducible by heat alone, and which do not decompose water under any circumstances; they are mercury, silver, palladium, platinum, gold, and probably rhodium and iridium. The protoxides of the metals are uniformly and strongly basic, but in the high degrees of oxidation of which some metals are susceptible the combinations are of acid character. All the metals combine with sulphur, forming sulphurets or sulphides, and in this combination they are more commonly found in nature than in the metallic state or in other compounds.

METALLOID (Gr. *μεταλλος*, a metal, and *ειδος*, appearance; having a resemblance to a metal). In the classification of simple bodies, as observed in the preceding article, two divisions are recognized, the one of metals and the other of metalloids. The metallic bases of the fixed alkalis and alkaline earths have sometimes been called metalloids; but the bodies usually recognized by chemists as belonging to this division are the following: oxygen, hydrogen, nitrogen, sulphur, selenium, tellurium, chlorine, bromine, iodine, fluorine, phosphorus (arsenic?), boron, silicon, carbon.

METALLURGY (Gr. *μεταλλος*, metal, and *εργον*, work), the art of the treatment of ores in order to obtain the metals they contain. The processes peculiar to each variety of ore are partially described in this work in treating of the metals, so that little more is requisite in this article than to allude to some of the general operations and the apparatus employed. In a few metals are found in workable quantities "native" or uncombined; for an account of the mechanical processes in use for separating them reference may be made to the article GOLD. In the ores are obtained from their veins, they are more or less mixed with stony matters called their gangue, beside being themselves chemically compounds of a metal with some substance, as sulphur, oxygen, carbonic acid, &c., in which state they have little of the metallic appearance.

peace, but like a lion in war." Nearly all metaphysical terms are metaphorical, their application being transferred from physical to spiritual phenomena; and a large proportion of the words in common use are employed in a metaphorical sense.

METAPHYSICS. See **PHILOSOPHY**.

METASTASIO, **PIETRO ANTONIO DOMENICO BONAVENTURA**, an Italian poet, born in Rome, Jan. 3, 1698, died in Vienna, April 12, 1782. His father had removed from Assisi to Rome, and although reduced in circumstances and successively a soldier, an amanuensis, and a pastry cook, he was enabled to place his son at a grammar-school. Pietro's taste for poetry was powerfully stimulated by the reading of the works of Tasso, and he is said to have excelled in improvising verses at the age of 10. Gravina, an eminent jurist and scholar, greatly impressed by his talents, adopted him as a son, changing his name of Trapassi to that of Metastasio (from the Gr. *μεταστροφή*, change or transfer), and preparing him for the profession of the law, but without discouraging his studies in classical and dramatic literature, in which he advanced so rapidly that at 14 he wrote a tragedy, *Giustino*, after the model of the Greeks. He accompanied his patron to Naples, where his remarkable powers of versification and elocution, and the charm of his manners and conversation, gained him many friends. He continued to study jurisprudence, and also took holy orders, whence he was sometimes called Abbate. Gravina bequeathed him on his death in 1717 a considerable fortune; but the prodigal young poet squandered most of it within 2 years, and for a short time again applied himself to the study of the law. Soon returning to his favorite pursuit, he produced an epithalamium and the drama *Endimione*. Under the patronage of the viceroy of Naples he wrote *Gli orti esperidi* and *Angelica*, the latter after Ariosto. The part of Venus in the former play was performed by Maria Bulgarini, or La Romanina, who was at that time the leading Neapolitan prima donna, and whose appreciation of Metastasio's genius laid the foundation of a most intimate relation, the poet taking up his residence in her husband's house, and writing under her inspiration his *Didone abbandonata* (1724), which was set to music by Sardi and other composers, and established Metastasio's fame. He accompanied the signora to Rome, where his *Semiramide* (set to music by Meyerbeer in 1819), *Ezio*, *Alessandro nell' India*, *Calone in Utica*, and *Artaserse* (the last well known in an English version) were performed in rapid succession. In 1729 he went to Vienna, where he succeeded and soon surpassed Zeno as imperial laureate, and occupied himself in supplying the court with lyrical dramas and oratorios, composing miscellaneous poetry, and teaching music and Italian to the Austrian princesses. In 1733 appeared his *Olimpiade*, which was honored with the epithet "divine" by his enthusiastic countrymen; and one of his most celebrated lyrical dramas, *La clemenza di*

Tito, was performed in 1734, and was again set to music, with great success, in 1790 by Mozart. The death of the emperor Charles VI. in 1740, and the outbreak of war, led to the closing of the theatre in which he had been employed, and he now devoted himself to literary pursuits, chiefly to translations and annotations of Greek writers. In 1744 appeared his plays of *Antigone* and *Ipermestra*. After the return of peace (1751) he wrote *Il re pastore*, which was enacted by the ladies of the imperial family. His last operatic play, *Il ruggiero*, was produced at Milan on occasion of the marriage of the archduke Ferdinand (1771). La Romanina had bequeathed to him on her death in 1734 the reversion of a considerable amount of property, but Metastasio restored to her husband the right of disposing of it; yet, notwithstanding a generosity which bordered upon recklessness, he amassed in the latter part of his life a large fortune, which he bequeathed to the children and chiefly to the son of his friend Martinetz, whose hospitality he had enjoyed when he first went to Vienna. His last occupation was the superintendence of the magnificent Paris edition of his works. Metastasio was beloved as much for his amiable character as for his genius. He was as gentle in his life as in his writings, and young aspirants to fame had no more devoted friend than the venerable poet, who was among the first to recognize the genius of Mozart, and to express his admiration of a comic opera which the youthful composer, then only 12 years old, had set to music in 1768 at the request of the emperor Joseph. Metastasio was a devout Christian, and Pope Pius VI., happening to be in Vienna at the time when he was taken ill, hastened to his deathbed and gave him his benediction. He was buried in the church of St. Michael, and in 1788 his bust was placed by Cardinal Riminaldi in the church of St. Mary at Rome.—Schlegel says: "A perfect purity of diction, a grave and unalloyed delicacy have rendered Metastasio, in the eyes of his countrymen, a classic author, the Racine of Italy. In the softness, tenderness, chasteness, and gentle pathos of his verse, he is not surpassed by any other poet of the musical drama; and although deficient in the genius of impassioned tragedy, he is unrivalled in his operatic plays." Although his dramas were set to music as soon as they were written, not a vestige of the original music now remains, except perhaps in the imperial library at Vienna. His best known oratorios are *La morte d'Abel*, *Isacco*; and *La passione*; and his most popular cantatas are *La liberta*, *La primavera*, and *La partenea*. A *catalogue raisonné* of his compositions is given by Dr. Burney. The best editions of his works are those in 12 vols. (Paris, 1780-'82), and 20 vols. (Mantua, 1816-'20).—See Burney, "Memoirs of the Abbate Metastasio," with translations of his principal letters (8 vols. 8vo., London, 1796). The best Italian sketch of his literary career is by Mauro Boni in his edition of Metastasio's works (Padua, 1811).

METASTASIS (Gr., from *μεταστροφή*, to transfer), in medicine, the sudden transference of diseased action or of a secretion natural or morbid from one part of the body to another. In the old days of the humoral pathology it was supposed that disease was always caused by some alterations of the fluids, while its local manifestations were often produced by an effort at elimination by the part affected; that, if immediately on the retrocession of measles the patient was attacked with pneumonia, the peccant humor was transferred from the lungs to the skin; that in rheumatism and gout the joints were left and the heart attacked; that hæmorrhage from the lungs occurred as a consequence of suppressed menstruation; and that milk leg had its origin in the transference of that secretion from its normal position to the affected limb. Larger observation and clearer insight have shown the facts to be wrongly interpreted and the theory false. In rheumatism the lining membrane of the heart and the pericardium form portions of a series of analogous tissues which are liable to be attacked, and these tissues are attacked at one or several points, irrespective of any transference of morbid action from one point to another. So when an internal organ is seized with inflammation, an eruption on the skin is apt to fade, this fading being a consequence, not a cause, of the inflammation. Milk leg (*phlegmasia alba dolens*), it is discovered, is caused by inflammation of the veins, and has nothing to do with the retrocession of the milk. When a discharge of blood takes place from the surface of an ulcer or some other abnormal position in cases of suppressed menstruation, it must be regarded as an effort to relieve a periodic plethora. These cases, however, are found to be extremely rare, the part which they play in the old books giving an entirely erroneous idea of their frequency.

METCALFE, **CHARLES THEOPHILUS**, baron, an English statesman, born in Calcutta, Jan. 30, 1785, died at Basingstoke, England, Sept. 5, 1846. He was the second son of Major Thomas Theophilus Metcalfe of the Bengal army, who was made a baronet in 1802. Charles, while yet an infant, was taken to England by his parents, was educated at Eton, and at the age of 15 was sent to India as a writer in the East India company's service. In Dec. 1801, he was appointed assistant to the English resident at the court of Dowlut Row Sindia at Oojein. He soon displayed great diplomatic talent, and rose rapidly in the civil service of the company. In 1811 he was appointed to the important post of resident at Delhi; in 1819 he became political secretary at Calcutta, and in the following year resident at Hyderabad. On the death of his elder brother in 1823, he succeeded to the baronetcy, and 4 years afterward was made a member of the supreme council of India, the highest post beneath that of governor-general. In 1836 the grand cross of the bath was conferred upon him, and he was appointed lieutenant-governor of the North-Western provinces; in Aug. 1837, he resigned and returned

to England. He remained in retirement till June, 1839, when he was solicited by the ministry to accept the government of Jamaica, that colony being then convulsed by the difficulties attendant upon the transition of the negroes from slavery to freedom. He accepted the post, and in the course of 8 years completely restored order and contentment in the island. Ill health compelled him in 1842 to resign and return to England. The legislature of the colony, grateful for his services, subsequently ordered his statue to be erected in the public square of Spanish Town. Early in 1843 the ministry again had recourse to his great administrative talent, and persuaded him to accept the governor-generalship of Canada. He held this responsible and difficult position, to the satisfaction of all parties, till the latter part of 1845, when, after enduring terrible suffering from an incurable cancer which had long afflicted him, he resigned his office and returned to England to die. He had been raised to the peerage in 1844. His epitaph, written by Macaulay, terms him "a statesman tried in many high offices and difficult conjunctures, and found equal to all," and says that "costly monuments in Asiatic and American cities attest the gratitude of the nations which he ruled."—See "The Life and Correspondence of Charles Lord Metcalfe," by John William Kaye (new ed., 2 vols., London, 1858).

METCALFE, **THOMAS**, an American statesman, born in Fauquier co., Va., March 30, 1780, died in Nicholas co., Ky., Aug. 18, 1855. When he was a child his parents removed to Kentucky, and settled in Fayette co. After a few months' attendance at a country school he was apprenticed to a stone mason, and worked assiduously at his trade, but devoted his leisure hours to books. In 1809, when the relations of the United States with England assumed a threatening character, he publicly advocated war, and was afterward chosen a captain of infantry, and distinguished himself in the north-western campaign under General Harrison, especially at the siege and battle of Fort Meigs. Returning to Kentucky after the war was over, he was elected to the legislature, where he served 4 or 5 years. In 1819 he was elected to congress, and served by successive re-elections till 1828, when he became a candidate for the office of governor of Kentucky. After an exciting canvass he was elected by a decisive majority, and held the office for 4 years. In 1834 he was elected a member of the state senate, and in 1840 became president of the board of internal improvements. This office he held until June, 1848, when he received from the governor of the state the appointment of U. S. senator, to fill a vacancy occasioned by the resignation of J. J. Crittenden; and on the meeting of the legislature he was elected for the residue of the term, which expired March 3, 1849. He then retired to his farm in Nicholas co., and never afterward sought office. In politics Gov. Metcalfe was a conservative whig.

METELLUS, a plebeian family of the *Cæcilia gens*, numerous members of which were conspicuous in the later periods of the Roman republic. The following are the most distinguished. I. **Lucius Cæcilius Metellus**, commanded against the Carthaginians in the first Punic war, defeated Hasdrubal in 250 B. C., and was honored with a triumph; was twice consul, once dictator for the purpose of holding the comitia, and pontifex maximus during the last 22 years of his life; lost his sight while rescuing the Palladium from fire, and died about 220 B. C. II. **Quintus Cæcilius Metellus**, son of the preceding, served successively as plebeian ædile, curule ædile, consul, proconsul, and dictator for the purpose of holding the comitia; fought in the second Punic war against Hasdrubal in Spain, and against Hannibal in Bruttium, and survived the final victory over the Carthaginians many years. III. **Quintus Cæcilius Metellus**, surnamed **Macedonicus**, son of the preceding, commanded as prætor in Macedonia, where he defeated and made prisoner the usurper Andiscus (148), fought successfully against the Achæans (146), and as consul against the Celtiberians in Spain. He was censor in 131, and died in 115 after a long career of honors and private happiness, and was carried to the funeral pile by 8 sons who had officiated as consuls, and a 4th who was candidate for the same dignity. The 1st, 2d, and 4th were afterward distinguished by the surnames of *Balearicus* (from the conquest of the Balearic isles), *Diadematus*, and *Caprarius*. IV. **Lucius Cæcilius Metellus Dalmaticus**, nephew of the preceding, officiated as consul, censor, and pontifex maximus, received his surname from his victories over the Dalmatians in 119 B. C., and was active against the demagogue Saturninus 19 years later. V. **Quintus Cæcilius Metellus Numidicus**, brother of the preceding, was distinguished alike by his great integrity and rare abilities in peace and war. He commanded as consul in 109, and as proconsul in the following year, against Jugurtha in Numidia, but had the mortification to see the fruit of his victories, the honor of a final triumph over the enemy, snatched from his hands by Marius, his legate, who supplanted him in the opinion of the Roman people by artful calumnious rumors, and was elected consul to succeed him in command. He was, however, allowed a triumphal entry into Rome (107), and subsequently elected censor (102). Two years later Marius, now the idol of the *plebs*, concerted with the tribune Saturninus a scheme to destroy the influence of Metellus, who was regarded as the foremost leader of the aristocratic party. Saturninus moved and carried through an agrarian law, with an additional enactment requiring the senators to take an oath of fidelity to the same, under penalty of being expelled the senate. Metellus remained faithful to his convictions, suffering with calm resignation not only expulsion from the senate, but subsequently also the heavier blow of banishment from Rome.

He retired to Rhodes, whence he was recalled in the following year, on the proposition of the tribune Quintus Calidius. Metellus was no less renowned for his oratorical powers than for his civic virtues. His orations are praised by Cicero, and were still admired in the time of the Antonines. VI. **Quintus Cæcilius Metellus Pius**, son of the preceding, received his surname from his filial efforts to bring about the recall of his father from exile. He commanded in the social war, tried in vain to save Rome from Marius and Cinna in 87, crossed over to Africa, and subsequently fought with distinction against the Marian party in Umbria, Cisalpine Gaul, and Spain, where his efforts proved insufficient against Sertorius. He was consul with Sylla in 80, and died while pontifex maximus, being succeeded by Julius Cæsar (68). VII. **Quintus Cæcilius Metellus Creticus**, great-grandson of Metellus Macedonicus, served as legate under Pompey in Asia, and as prætor in Italy in the year of Cicero's consulship (68), with whom he actively coöperated against Catiline and his followers. On the outbreak of the war, being intrusted with the command in Picenum and the Senonian district in upper Italy, he greatly contributed to the defeat of Catiline by blocking up the passes of the Apennines, and thus compelling him to face the army of Antonius, Cicero's colleague. In 62 he was sent as proconsul to Cisalpine Gaul, in 60 officiated as consul with Afranius (opposing the schemes of Pompey, who was better served by his colleague as well as by his younger brother Nepos), and died in the following year, it was suspected from poisons administered him by his profligate wife Clodia. VIII. **Quintus Cæcilius Metellus Pius Scipio**, the adopted son of Metellus Pius. (See *Scipio*.) IX. **Quintus Cæcilius Metellus Creticus**, received his surname from the conquest of Crete, whither he was sent as consul in 69, and whence he returned in 66, but was prevented by his political opponents, the friends of Pompey, from celebrating a triumph till after the defeat of Catiline, during whose agitation he had prevented an insurrection of the slaves in Apulia.

METEMPSYCHOSIS (Gr. *μετα*, denoting change, and *ψυχη*, soul), the supposed transmigration of the soul from one body to another. The idea belongs to the oldest religions of India and Egypt, and is one of the earliest forms in which the doctrine of immortality appears. It regards human life on the earth as only one link in a chain of conditions, through which the soul passes in its long career of procession from God and return to him. It is a prominent feature in the systems of Brahminism and Buddhism, which represent the migration after death into the body of a higher or lower animal as a reward of virtue or penalty for vice. The soul may even deteriorate into the vegetable or mineral world. It accomplishes 84 transmigrations before it rises to human consciousness, reason, and freedom, and is then liable to be returned to begin the series again. A period of

12,000 divine years, each embracing 860 human years, is assigned for the completion of its transformations and for the process of purification, when it ultimately receives its reward in what is described as a state of blissful absorption in the divine nature. According to Herodotus, the Egyptians were the first to entertain this doctrine. They believed that the soul was clothed successively with the forms of all the animals that live on the earth, and that it then returned after a cycle of 8,000 years into the body of a man, to recommence its eternal pilgrimage. From them the Greeks may have received the idea, which was a leading feature of the Pythagorean philosophy. The later Pythagoreans maintained that the soul has a life peculiar to itself, which it enjoyed in common with demons or spirits before its descent to the earth, and that there must be a degree of harmony between the faculties of the soul and the form which it assumes. After freeing itself from the fetters of the body, and remaining for a time in the realm of spirit, it returns to the earth to accomplish again the process of purification through a series of animals and human bodies. Plato adopts and treats the doctrine in his *Phædo*, maintaining the preëxistence of the soul before it appears in man, of which condition it retains dim reminiscences; and after death, according to its peculiar qualities, it seeks and chooses another body. Every soul, according to him, returns to its original source in 10,000 years. After completing each life it spends 1,000 years in the infernal world in a condition corresponding to that life, after which it passes into a new body corresponding to its ethical quality. The idea of metempsychosis subsequently appears in the speculations of the Neo-Platonists, in the cabala of the Jews, and in the teachings of one of the church fathers. Porphyry gave to it its most definite development in Neo-Platonic thought. He conceives that it is to expiate sins committed in a preëxistent state that we are now clothed with a body, and that as our conduct was more or less culpable we assume more or less material bodies. By fulfilling exactly and with resignation the duties imposed upon us, we return by degrees through the state of heroes, angels, archangels, &c., to the Supreme Being. There is also a descending scale of diabolical life. The cabalists thought that the destiny of every soul was to return into mystical union with the divine substance, but that in order to do this it must first develop all the perfections of which it has the germ within itself. It is sent through life after life till it acquires all the virtues possible to it. According to some cabalists, God created a definite number of Jewish souls, which, though sometimes transferred for penance to the forms of animals, are ever reappearing among men, and constituting the Jewish race; and that on the morn of the resurrection they will all dwell in the bodies of the just in the Holy Land. Origen distinctly maintains the doctrine, and finds in it the final cause of creation. In his view, God gave

existence to the world, not to manifest his power or any other of his attributes, but as a place of chastisement for those souls which had sinned in heaven; and this design explains why the Deity introduced so many apparent imperfections into his work. The idea appears in the tenets of the Gnostics and Manichæans, and of some other heretical sects. It was also a part of the doctrine of the druids, and is still believed by the Druses and various other tribes in western Asia and in Africa. Fourier attempted to revive it in a new form. According to him, it is the destiny of the soul to pass through 810 lives, embracing altogether a period of 81,000 years, 27,000 of which will be spent on this planet. When all the transmigrations have been accomplished, every soul will lose its separate existence, and all will become confounded with the soul of the planet, the stars being animated like men. The body of our planet will in its turn be destroyed, and its soul will pass into a new globe, and rise through an infinite number of successive transformations to the highest degrees in the hierarchy of worlds.

METEOR (Gr. *μετεωρος*, lofty, in the air), any phenomenon of short duration occurring in the atmosphere. Rain, snow, hail, fog, and dew are meteors distinguished as aqueous; the movements of the winds constitute the varieties of aerial meteors; luminous meteors are the singular phenomena displayed by the action of the aqueous particles diffused through the atmosphere upon the rays of light, such as *fata Morgana*, halo, mirage, rainbow, &c., and may also include the aurora borealis; and igneous meteors are such phenomena as lightning, *aërolites*, shooting stars, &c. Most of these are described in this work under their own names.—In common language, the term meteor is applied only to those bodies which, as globes of fire or as shooting stars, are occasionally seen darting through the heavens at unknown distances from the earth, and in undetermined paths. Sometimes exploding and projecting upon the earth fragments of stone called meteoric iron, they are proved to be solid bodies in a state of intense heat, and are then known as *aërolites* or meteorolites. In ancient times these bodies were witnessed in different parts of the earth, and their appearance was chronicled as among the most wonderful natural exhibitions. The Chinese records of such phenomena extend back to 644 B. C.; and from the 7th century B. C. to A. D. 888, 16 falls of *aërolites* are recorded in the astronomical annals of the Chinese. By the Greeks and Romans in the same period accounts are preserved of only 4 such falls. Humboldt states that it is remarkable that the Ionian school, in accordance with the present opinion, early assumed the cosmical origin of meteoric stones. Anaxagoras of Clazomenæ held that the meteors are masses torn away from the earth by the violence of the rotation; and that between the earth and the moon there revolve other dark bodies which can produce eclipses of the moon. Dr

ogenes of Apollonia, as recorded by Stobæus, also taught that dark masses of stone move with the visible stars and remain unseen by us. Plutarch in the life of Lysander (cap. xii.) expressly declares that falling stars "are really heavenly bodies, which from some relaxation of the rapidity of their motion, or by some irregular concussion, are loosened and fall, not so much upon the habitable part of the globe as into the ocean, which is the reason that their substance is seldom seen." Considerations like these suggested by the fall of cosmical bodies to the earth thus led in Grecian antiquity to the perception of a centrifugal revolution of the heavenly bodies, and, as a necessity, of a centripetal force also, holding the bodies in their orbits, which is distinctly alluded to by Simplicius, the commentator on Aristotle, who describes it as a "fall force" or "drawing downward."—The nature and movements of the meteoric bodies which fall upon the earth have already been considered under *ÆROLITE*. But some of the most extraordinary meteoric displays, of the nature of fire balls or bolides, and of shooting stars, not being accompanied by falls of stone, may properly be noticed in this place. The bolis is the fiery body from which *ærolites* are precipitated upon the earth; but many such bodies pass across the heavens, and sometimes explode and disappear, leaving behind no vestiges of their solid materials. They appear singly at irregular periods, and move with great rapidity across the sky, exhibiting sometimes a dazzling brilliancy, greater than that of the sun at noonday, as is remarked by Humboldt of one seen at Popayan in 1788. A luminous train follows them, and their path has been known to remain brilliant for several minutes after they have disappeared. Admiral Krusenstern, indeed, in his "Voyage," describes a fire ball the train of which shone for an hour after the body had disappeared, scarcely moving during this time. They send forth vivid scintillations and present various bright colors, and the same meteor is differently described as seen from different places. Often they divide into two or more bodies which keep along together, and sometimes explode with a report like heavy thunder. They are of various apparent sizes, sometimes exceeding that of the moon. Their altitude varies as they approach the earth, and again move away from it as they continue on their course. On Feb. 6, 1818, one was seen in England at about 2 P. M. descending vertically and shining with a light equal to that of the sun. Dr. E. D. Clarke, who described this in the "Annals of Philosophy," vol. xi. p. 278, was of opinion that meteorolites fell from this body; and in Lincolnshire it was reported that a hissing noise accompanied it, and a trembling of the earth was felt like the shock of an earthquake. The records of fire balls seen in the evening are very numerous. They appear at no particular season, and are limited to no particular portions of the earth, though most of the observations have been recorded in Europe. In 1623

one was seen over Germany, and described by Kepler. In 1676 one passed over Italy from the direction of Dalmatia about 2 hours after sunset, and disappeared toward Corsica. At Leghorn it was heard to explode, and fragments from it fell into the sea. Its height was estimated by Montanari at 88 m. Halley describes in the "Philosophical Transactions," No. 860, a meteor of extraordinary brilliancy which appeared over England in 1719 at about 8½ P. M. It suddenly illuminated the streets of London, causing the stars to disappear, and the moon, which before was shining brightly, to be hardly visible. The eye directed toward it could scarcely bear its brilliancy. It moved like a falling star at a height estimated at 60 to 70 m., and with a velocity of 800 to 850 m. in a minute; through Devon and Cornwall and on the opposite coast of Brittany a loud explosion was heard proceeding from it. On Aug. 18, 1788, at 9 P. M., another very remarkable meteor of this character was seen over a large part of Europe from the N. of Ireland to Rome. It crossed the zenith at Edinburgh, appearing single and well defined, of a greenish shade, and with a tail; but at Greenwich it had the appearance of two bright balls with other luminous bodies following it. Its height was estimated to be above the limits of the atmosphere, its speed more than 1,000 m. a minute, and its diameter more than a mile. Cavallo describes its bursting and the noise of the explosion, which was 10 minutes in reaching the earth. Bowditch describes, in the "Memoirs of the American Academy," a meteor seen Nov. 21, 1819, at Danvers, Mass., and in Baltimore, Md., the diameter of which appeared to be half a mile. Its direction was S. 44° W., and its height, at first 88 m., was soon reduced to 22 m. Two minutes after its disappearance a rumbling noise was heard which lasted longer than a minute. On the evening of July 20, 1860, at about a quarter before 10 o'clock, a meteor passed over the state of New York, from the west, being seen on Lake Erie, and soon afterward at Buffalo, Albany, New York city, New Haven, Newport, R. I., and New Bedford, Mass. At the south it was visible in the state of Delaware. By many observers it was at first supposed to be a display of rockets or of Roman candles; and all had the impression that its elevation was only a few hundred feet. From a vessel off Sandy Hook it appeared to fall into the sea at a short distance. First appearing as a single body, it was observed to separate into two balls, which kept along together, emitting sparks and what appeared to be flames. Whether these bodies move in eccentric orbits around the sun or around the earth is undetermined, and no explanation yet satisfactorily accounts for their ignition in the upper regions of the atmosphere, where this fluid through its extreme rarity can offer but very slight impediment to their motion.—Falling stars resembling small bolides are often seen on a clear night shooting at the rate of 4 or 5 an hour across the sky. These are termed

"sporadic" meteors, in contradistinction to the "periodic," which at certain periods appear often in vast numbers like showers of fire. Displays of this kind are recorded as occurring in Oct. 902; Oct. 19, 1202; and Oct. 21, 1866 (O. S.). Each time the stars are stated to have been in motion all night, falling like locusts, and in numbers which no one could count. More modern occurrences of this phenomenon were observed on the night of Nov. 9-10, 1787, in southern Germany; and after midnight of Nov. 12-18, 1799, as described by Humboldt and Bonpland, in Cumana. The same phenomenon was also observed as far south as the equator, and over North America, even to Labrador and Greenland, and on the other side of the Atlantic in Germany. From the bearing and course of the meteors at different points, their elevation was computed to be 1,419 m. In 1818 meteoric displays of great brilliancy were seen on the same night of Nov. 12-18, in England, and again in 1822 at Potsdam in Brandenburg. In some of the exhibitions about this period a deposit of dust was observed upon the surface of the water, on the buildings, and other objects. On the same night in 1831 and in 1832, the same phenomenon reappeared in Europe and America. But the year 1833 is memorable for the most magnificent display on record. This was on the same night of November also, and was visible over all the United States, and over a part of Mexico and the West India islands. Together with the smaller shooting stars, which fell like snow flakes and produced phosphorescent lines along their course, there were intermingled large fire balls, which darted forth at intervals, describing in a few seconds an arc of 30° or 40°. These left behind luminous trains, which remained in view several minutes, and sometimes half an hour or more. One of them seen in North Carolina appeared of larger size and greater brilliancy than the moon. Some of the luminous bodies were of irregular form, and remained stationary for a considerable time, emitting streams of light. At Niagara the exhibition was especially brilliant, and no spectacle so terribly grand and sublime was ever before beheld by man as that of the firmament descending in fiery torrents over the dark and roaring cataract. It was observed that the lines of all the meteors if traced back converged in one quarter of the heavens, which was γ Leonis Majoris; and this point accompanied the stars in their apparent motion westward instead of moving with the earth toward the east. The source whence the meteors came was thus shown to be independent of the earth's rotation and exterior to our atmosphere. As computed by Prof. Denison Olmsted of New Haven, it could not have been less than 2,238 m. from the earth. Three successive annual returns of this phenomenon on the same night led astronomers on both sides of the Atlantic in the following years to watch for its recurrence; and displays more or less brilliant, but not by any means equal to that of 1833,

were witnessed in different places in Europe or America every year till and including 1839. They were again observed on the night of Nov. 12-18, 1841 and 1846. Olbers, the astronomer, supposes the real period of return to be 34 years, and that the display of 1799, repeated in 1833, will reappear in 1867. But it is not alone in November that periodic exhibitions of the fall of meteors have been observed. It is found that they often occur about the 10th, or from the 9th to the 14th of August; and Humboldt names other periods that are likely to prove of the same interest, as about the 22d to the 25th of April; between the 6th and 12th of December; the 27th and 29th of November; and about the 17th of July. He notices the singular coincidence which different observers have remarked in the great brilliancy of the aurora borealis during the fall of the meteors. As explained by Prof. Olmsted, the meteors probably emanate from a nebulous body, which revolves around the sun in an elliptical orbit, the aphelion of which meets the orbit of the earth at the times of the annual exhibitions. The nebular character is inferred from the fact that none of the meteors, though they fall toward the earth with prodigious velocity, ever reach it in a solid state, all being dissipated in the atmosphere, and no material substance found to indicate their nature. The theory of Arago is similar to that of Olmsted. He suggests that the meteoric bodies may constitute a stream in the form of an annular zone, within which they pursue one common orbit; that there are several such streams, which intersect, each at its own period, the earth's orbit; and that through each the myriads of small cosmical bodies are irregularly dispersed. It is in passing the densest groups of these that the most brilliant meteoric displays occur. The subject is treated at length in the 1st and 4th vols. of Humboldt's "Cosmos."

METEOROLOGY (Gr. *μετεωρος*, lofty, above the earth, and *λογος*, discourse), the description and explanation of the various changes which occur in the region of our atmosphere. These changes are apparently so capricious that at first sight they would seem to be governed by no law; yet, although we are not able to predict the recurrence of the phenomena, much has been done toward referring them to the general principles on which they depend. In this place we purpose to give a brief exposition of these principles, referring to the several articles on ATMOSPHERE, CLIMATE, CLOUDS, DEW, and the like, for a more particular account of the phenomena themselves. In order to convey the greatest amount of knowledge in a definite form and the least number of words, we shall adopt the synthetical method, and endeavor to show, by the combination of known laws, the general phenomena which would be presented by a body like our earth situated in mid space, composed of known materials, and subjected to definite influences.—The earth is a spherical body, slightly flattened, isolated in space, turning uniformly around an ideal axis which pierces its

surface in two points or poles, while it describes a curve slightly elliptical round the sun once in a year. It is surrounded with an atmosphere of such extreme mobility that the lightest force produces changes in it of a meteorological character, and hence the variety and complexity of this class of phenomena. The earth at present does not appear to possess any power of producing, except in a small degree, spontaneous changes in its surface which could affect its meteorology. Geologists teach that the temperature of the interior of the globe is still higher than the melting point of the most refractory metals, and that this original heat of the earth in past geological ages has been active in transforming the crust of the globe; yet it is conclusively shown from other considerations, that at present the cooling is so far advanced that the internal heat does not perceptibly affect the temperature of the external surface. We are therefore to look for the motive power of nearly all the changes going on around us to forces from without; and in considering these we shall begin with radiation from the stars.—It is well known that at one time the stars were supposed to control human destiny; and although modern science has discarded most of the pretensions of astrology, yet in this instance it has shown that the stars have really a physical influence upon the earth. If from any point a line be extended in thought in any direction, it will ultimately reach a radiating body; and hence every point within the stellar universe must be constantly traversed in all directions with radiating impulses, which must impart to a body in space a given temperature. If the radiation then from the stars continue invariable, what is called the temperature of celestial space will be without change. According to the dynamic theory of heat, if there were no stellar radiation, and an absolute cessation of the vibrations which constitute this principle, the expansion of all bodies would cease at a temperature of about 500° below that of freezing water. According to the experiments of Pouillet, made with an artificial sky, the heat of celestial space is 254° below the freezing point of water, and consequently about 246° above the absolute zero of temperature. From this it is evident that our globe actually receives an immense amount of heat from the stars, which is invariable in quantity, and nearly of equal intensity on every part of the earth's surface. The temperature is still further increased by the accumulating property of the atmosphere, which transmits to the earth the heat of high intensity of the stars, and confines the dark heat which alone radiates from the earth. In this way, according to Pouillet, the temperature of the surface of the earth is elevated 94° above that of celestial space. It is still 160° below that of freezing water, and far below the point at which life can exist on the globe. The heat therefore which produces motion on the surface of the earth, and is alone compatible with animal and vegetable vitality, is that from the sun. If the earth

revolved round this luminary on an axis perpendicular to the plane of its orbit, there would be no variations of seasons, and throughout the year every part of the earth would experience nearly a uniform temperature, decreasing in intensity as the cosine of the latitude each way from the equator to the poles. But from the simple fact that this axis inclines about 23° from the perpendicular, the two poles are alternately turned to and from the sun, and hence result the complex and varied changes of spring, summer, autumn, and winter. A small variation is also produced in the temperature on account of the elliptical form of the earth's orbit. The earth must actually receive during 24 hours, when it is nearest the sun, a greater amount of heat than during the same time when it is at its greatest distance from it. Thus in the present century the earth is nearest the sun on the 1st day of January, and consequently receives on that day the greatest amount of heat; and is furthest from the sun on the 4th day of July, and on that day receives a less amount of light and heat than on any other day of the year. (See Meech, "Smithsonian Contributions to Knowledge," vol. ix. 1857.) Sir John Herschel, however, has shown that although there is a greater amount of heat received during a day in the one position than in the other, yet the whole amount received in the course of a year will be the same as if the earth revolved in a perfect circle of which the sun occupied the centre, since the rapidity of motion in the different parts of the orbit will be inversely as the quantity of heat received; or in other words, the greater length of time to which the earth is subjected to a less heat just compensates the greater heat in less time. But in this calculation, the effect of cooling has been left out of view; the earth is not only receiving heat at every moment, but is constantly radiating it into space. When the amount given off is just equal to that received, it is as a whole in a state of equilibrium with regard to heat; but when the amount given off is greater than that received, then, although the radiation or cooling from the earth as a whole is very nearly the same as it would be if the earth revolved round the sun in a circle, yet the temperature of the southern portion of the earth must be less, other things being the same, than that of the northern, on account of its longer winter and our longer summer, or in other words, on account of the longer time during which it is exposed to radiation without the compensating influence of the sun's rays. To this difference has been attributed the greater accumulation of ice at present at the south pole; and from it the inference has been drawn that, inasmuch as the elliptical figure of the orbit is constantly changing its position in space, in the course of 5,025 years, when the ellipse shall have so changed as to bring the nearest point of the orbit to the sun in the period of winter in the northern hemisphere, then the reverse condition will exist, namely, a greater accumulation of ice and a

more rigorous climate at the north.—The temperature, however, of a body in space like that of the earth, does not merely depend upon the amount of heat it receives from surrounding bodies, but also upon the nature of the transparent envelope or atmosphere which surrounds it. If we suppose heat to consist of vibrations of different lengths given off from all heated and luminous bodies, we might then infer what is really the case, that heat from different sources would possess different penetrating powers in regard to different substances. Now luminous rays, such as those which come from the sun and stars, readily penetrate transparent bodies; while dark rays, such as are given off from a vessel of boiling water or earth heated below redness, are stopped by these media. The atmosphere which surrounds the earth, as we have said, performs a similar part; it suffers at least three quarters of all the heat which falls perpendicularly upon it to reach the earth, and to warm the surface. This surface, however, radiates heat in turn, but not of the quality which can readily pass out into space through the atmosphere; it is therefore retained at the surface of the earth, of which the temperature is gradually increased until an equilibrium is produced between the amount received and that given off by radiation, an equilibrium which takes place at a temperature at the equator of about 82° F., and at zero of the same scale at the poles. We can see from this that, with an atmosphere that would more readily admit rays of high intensity and less readily radiate those of low intensity, the temperature of the surface of the earth would be much higher than it is even if it were situated at a greater distance from the sun. Were the earth covered with a surface of uniform material and without an atmosphere, its relative temperature at different times and on different parts of its surface could readily be calculated; but the diversity of the surface and the motion of the aerial covering give a complexity to the subject which renders the complete solution of the problem almost impossible. We are however able to obtain a general appreciation of these effects. Let us first consider the mechanical constitution and effects of the atmosphere. We may suppose this to be composed of atoms self-repellent, but subject to the attraction of gravitation, and therefore possessed of weight. The lower strata of such an atmosphere must be more dense than the upper, since each succeeding stratum as we pass downward is pressed into less space by the weight of all the superincumbent strata. A column of this atmosphere at the bottom has the temperature of the surface of the earth, and at the top that of celestial space, the temperature diminishing as we ascend, at least for accessible distances, on an average about 1° for each 800 feet. In order that such an atmosphere may be in a state of equilibrium, it is necessary to admit that each successive pound of air from the bottom to the top contains nearly the same absolute amount of heat,

the latent heat increasing and the temperature diminishing as we ascend; for in this case, if a portion of air be forced upward by any mechanical means, it will expand from a reduced pressure, and in thus expanding will diminish in temperature, since the same amount of heat which existed in a cubic foot of air at the bottom of the column is now distributed through a larger space; and if a portion of the same fluid be brought down to a lower level, its temperature will rise, its density increase, and it will be again found in the same thermal and mechanical equilibrium. In order therefore to a stable equilibrium, one that is not readily disturbed, the superior stratum of atmosphere ought really to contain a little more heat than the inferior one. The ascent and descent of air therefore into the atmosphere, if effected by mechanical means, could produce little or no change of temperature. The blowing of a wind, if it be perfectly dry, over a high mountain ridge, ought not to decrease its temperature, since the cold produced by the expansion would merely reduce the warm current from below to the normal temperature at the top of the ridge; and if the current continued its passage and descended on the other side to the level of the sea, it would be again of the same temperature as when it began to ascend. This, however, will not be the case with a mixed atmosphere, containing as ours does a considerable amount of vapor of water. The latter, by being carried up to a high elevation, will deposit a portion of its vapor on account of the reduction of temperature, and in doing this will give out a portion of its latent heat to the surrounding air, and prevent the temperature of this from sinking as low as it would were it not subjected to this influence; and in this case the air will descend to the level of the sea actually warmer as well as drier than when it went up. Although the mean temperature for a whole year of a wind blowing over a mountain ridge would be little or nothing diminished, yet if it blows over in summer or when the mountain is abnormally cooled with the remains of winter snow, the temperature of the wind will be less than that of the air in the plain below.—Again, it is evident that the temperature of a particular part of the earth must depend not only on the amount of heat which it receives directly from the sun, but also on the direction and quality of the winds to which it is subjected. When water is converted into vapor, as we have seen in evaporation, a large amount of heat is rendered latent; and when the vapor is condensed again into water, under whatever conditions the condensation takes place, the same amount of heat must be evolved. Every foot of water, therefore, which falls in the form of rain, must leave in the atmosphere as much heat as that required to reconvert the same amount of water into the state of vapor. We see from this simple consideration that the vapor contained in the atmosphere carried by the winds from one part of the earth to another, distributes and equalizes the heat which the ra-

diation from the sun tends to accumulate in the equatorial regions. Let us therefore next consider the circulation of the winds, than which at first sight nothing would appear more uncertain. The motion, however, of every particle of matter on the surface of the earth, is governed by laws as fixed and immutable as those which control the movements of the planets of our system, although, when the conditions under which these laws operate are much diversified and various perturbing influences are introduced, the resultant is difficult of estimation. Such is the case with the motion of the winds; still their general circulation has been made out with considerable certainty. If our earth were subjected alone to the heat of the stars, this being equal on all sides, no motion of the air would ensue; but the circumstance that the perpendicular rays of the sun are confined to the torrid zone, gives a great preponderance of heat in the equatorial regions, and hence causes a constant circulation of the air. The temperature of the equator is on an average about 82° , while the temperature of the polar regions is about zero. It follows from the law of expansion by heat, that the air at the equator will be enlarged in volume, and that its upper surface will tend to stand much higher than that at the pole. The air at the equator will therefore roll over toward the poles, increase the pressure on these parts of the earth, and diminish it in the equatorial regions. The heat being continued, the air would be pressed in from N. and S., would become heated, would ascend on account of the pressure on each side, and in this way a constant circulation would be kept up, below from N. and S. on either side, toward the equator, thence upward, and gradually turning backward, would flow above, N. and S. again, toward the poles. The greater portion of this circulation, however, would be confined to about the parallel of 30° on either side of the equator, since the impulse in a perpendicular direction, which the air receives in its ascent, would tend to carry it higher than the point due to the statical pressure. The greater portion would consequently descend before proceeding far N. or S., and this effect would be further increased by the narrowing of the meridians; for it must be evident that all the air which ascended at the equator could not descend in the frigid zones, since the area of these spaces is far less than that around the equator. The principal circulation will therefore be confined to a belt on each side of the equator extending N. and S. about 80° . A portion, however, would pass entirely to the pole, or rather to the coldest point in each hemisphere, where by losing its heat it would become denser and sink down toward the surface to return again toward the equator. Such would be the simple circulation of the aerial ocean if no perturbing influence existed; but a number of modifying conditions must be introduced. First, the earth is not at rest, but in rapid motion on its axis from W. to E. Every atom of air therefore, as

it flows toward the equator on either side, must partake of the motion of the place from which it started, and in its progress must in succession reach parallels of latitude moving more rapidly than itself. It would therefore as it were continually fall behind the surface of the earth, and appear to describe a slightly curvilinear course toward the west. We have in this a conception of the cause of the great system of currents denominated the trade winds, which blow constantly between the parallels of 30° N. and 30° S. toward the belt of greatest rarefaction, from the N. E. in the northern hemisphere and from the S. E. in the southern. This motion, however, requires further consideration. The particles of air approaching the equator do not ascend in a perpendicular direction, as we supposed in the first case, but gradually rise as they advance toward the W. along an ascending plane, and continue for a time their westerly motion in each hemisphere after they have commenced their return to the pole. When the atoms of air forming this current arrive at their greatest altitude, they begin to flow backward toward the poles; but as they flow, for example, those in the northern hemisphere northerly, they arrive at parts of the earth moving less rapidly than themselves, and therefore curve round toward the E., and finally descend to the earth to become again a part of the surface trade wind from the N. E. To render this motion more clear, let us suppose a series of books to be placed side by side on edge in a N. and S. direction. The leaves of these books will represent the planes in which the air would circulate in the northern hemisphere were the earth at rest; but if the earth is supposed to be in motion, then the upper edges of the books must be inclined to the W. so as to make an acute angle with the horizon and overlap each other like the inclined strata in a geological model. If, on each leaf of each book, a circuit of arrows be drawn moving toward the S. below and toward the N. above, the assemblage of these will represent the paths of the different streams of the atmosphere in our hemisphere. A considerable portion of the circulation we have here described must descend to the earth within about 30° of the equator, as we have before stated, and reaches the earth to form again the current of the surface trade winds. A part, however, descends still further N., and another portion probably reaches the colder part of the frigid zone. A part of the principal descending current in the latitude of 30° N., particularly during our summer, is driven under the higher strata, and gives rise to a surface wind from the S., which on account of the rotation of the earth becomes S. W. and covers to a comparatively small depth the whole of the northern temperate zone. A similar wind also exists in the southern hemisphere. The greater cold of the frigid zones tends to produce an effect similar to the greater heat of the torrid zone; the air becomes more dense and sinks toward the surface, producing a descending column analo-

gous but reverse to that at the equator, and flows in every direction from the pole, turning rapidly however to the W. on account of the rotation of the earth. The current at the surface, therefore, at the latitude of 60° , would assume a direction toward the W. The resultant winds consequently at the surface of the earth, in the northern hemisphere, as shown by Prof. Coffin, form three great belts: 1, in the region of the equator, a perpetual wind from the N. E. extending with a variable limit to nearly the latitude of 30° ; 2, between 30° and 60° or 65° , a variable wind, the greater amount of which is from the westward; and 3, in the frigid zone, a wind from the N. E. If we ascend sufficiently high in the atmosphere in the northern tropical regions, say at the island of Cuba, we shall pass through the strata of surface trades, and enter those of the upper or reverse trade winds moving from the S. W. toward the N. E. Again, if we ascend in the belt of temperate zones, for example above the city of Washington, we shall first pass through the surface current from the S. W., sometimes from the N. W., and higher in the atmosphere a continued current from the W. and N. W. On the borders of the northern frigid zone, in ascending from the earth, we shall first encounter a wind from the N. E., and higher in the atmosphere, flowing toward the cold pole, a wind from the S. W. Similar circulations must take place in the southern hemisphere. There are therefore in all six belts of winds on the surface of the earth, three in each hemisphere, and between them a narrow belt of comparative calms near the equator, in which the currents of the trade winds neutralize each other, and ascend into the higher regions. The descending current at about the latitude of 30° also produces a narrow belt of comparative calms in both hemispheres. To give as it were greater complexity to these perturbations of the circulation of the atmosphere, the systems we have described are not fixed in position, but move N. and S. with the varying path of the sun in the heavens during summer and winter. Another principal cause of perturbation in the circulation of the winds, and consequently in the distribution of heat, is the vapor which mingles with the atmosphere. This is absorbed in large quantities by the surface trade winds as they flow from either side of the equator over the ocean to the belt of centre calms; it is there elevated with the air, and in a greater part immediately condensed by the cold of the higher regions, and consequently falls in torrents of rain, leaving in the atmosphere all the latent heat which it had absorbed in its evaporation from the surface of the ocean. The heat thus evolved increases the ascensional power of the rising column, and causes it to ascend higher than it would otherwise do, and to fall on each side more precipitately and in greater quantity nearer the place of its ascent. In a like manner the introduction of vapor into any portion of the atmosphere expands it, and renders the strata unstable in a perpendicular

direction, giving rise to local upmoving columns, and thus producing winds, rain, and all the fitful local changes of the atmosphere. The winds not only carry the vapor which they have absorbed from the surface of the ocean, and deposit it on the land, but they also transfer the heat in a similar manner from one part of the earth to another, and thus constantly vary the temperature which a given place would have were it alone subjected to the influence of the sun.—Another primary cause of the irregular distribution of heat on the surface of the earth is the currents of the ocean. The unequal heating of different parts of the earth by the sun, as we have seen, gives rise to great gyratory motions of the air, and it must be evident that there will be a tendency to produce similar motions in the aqueous envelope of the globe. But the immediate effect of the heating of the water at the equator by the sun, although it has its influence, is not sufficient to account for the actual phenomena. We think the currents of the ocean are mainly due to the effect of the trade winds, which, if no obstruction existed, would produce a current toward the W. at the equator entirely round the earth. This current, however, is obstructed by the two continents which are stretched across its path, and is deflected right and left or N. and S. at the western shore of each ocean, thus forming four immense circuits, viz.: two in the Atlantic, one N. and the other S. of the equator, and two in the Pacific. For a like reason there is produced a similar whirl in the Indian ocean—the current from the E. being deflected down the coast of Africa, and returning again into itself along a southern parallel of latitude to the W. side of Australia. Beside these great streams, the waters supplied by all the rivers emptying into the arctic basin must flow out, and in their progress to the south must tend westward on account of the rotation of the earth producing a cold current from each pole along the E. shore of each continent, such as that which flows S. close to the shore along our coast. To illustrate the effect of these great gyrations of the ocean, let us consider the one which is best known, the Gulf stream. The trade wind, acting upon the waters near the equator, and sending them toward the W., gives rise to the great current which, interrupted by the islands of the Caribbean sea and the isthmus of Darien, is deflected along the E. coast of the United States, thence over to the coast of Europe, and down the coast of Africa, until it has completed its circuit in a period of from two to three years. In crossing the Atlantic it sends off a branch, as it were, which, passing among the islands of Great Britain, along the coast of Norway, and into the arctic regions, always tending eastward on account of the revolution of the earth, carries the water from the gulf of Mexico, one of the hottest portions of the earth, far to the N. and E., and produces an increase of temperature in these regions much above that which would be due to their position in regard to the sun.

Without this convective transfer of heat, Great Britain would be almost as inhospitable a region as the shores of Labrador, which are under the same parallel. This circuit produces very little effect, however, on the climate of the United States, since between it and our coast is the cold current from the north. Beside this, the heat which the eastern portion of our country might derive from the Gulf stream is carried away eastwardly by the prevailing westerly winds of the temperate zone. The gyration in the southern Atlantic is less marked, but still it carries the warm current along the coast of Brazil, which loses its high temperature by the time it has crossed the most southern point in the Atlantic ocean, and returns up along the western coast of Africa, to ameliorate the climate of that portion of the earth. The great currents of the Pacific are almost precisely similar in character to those of the Atlantic. Starting from the W. coast of America, the current, impelled by the trade winds toward the W., is deflected N. and S., and, divided into two great whirls by the continent of Asia and the adjacent islands, the northern flows along the coast of Japan and recrosses the ocean in the region of the Aleutian islands, and thence down the coast of Oregon and California to return into itself near the equator. This circuit, although it has very little influence upon the climate of China, materially affects that of the W. coast of North America. The water which ascends to the N. along the coast of Asia, loses a considerable portion though not all of its heat in crossing the Pacific, and, descending to the S. along the W. coast of America in a broad stream, imparts to the air in contact with it a mildness and equability of temperature which, carried eastward on to the land, imparts to our W. coast the agreeableness of its climate. The polar stream of cold water which flows out principally at the bottom of Behring's straits, tends, on account of the revolution of the earth, to hug the coast of Asia, and to flow between it and the Gulf stream of that region, as in the case of the streams on the E. coast of North America. A little reflection will enable the reader to trace out the effects of the other great whirls we have mentioned in the distribution of heat over the globe. But it ought to be stated, that in the descriptions we have given we have not considered the annual perturbations to which these currents are subjected on account of the varying position of the sun, and consequently the varying direction of the wind, our object being to give general views not too much complicated by multiplied conditions. It will be seen from an examination of the whole effect of the currents of the ocean, that on an average the isothermal lines, or lines of equal temperature, on the water, are carried farther to the north in the northern hemisphere and farther to the extreme south in the southern hemisphere than on the land. The temperature of the North American continent is perhaps more depressed than that of Europe and Asia, because the water which evaporates from Hud-

son's bay and the various inlets connected with it is restored by cold currents from the arctic regions. Perhaps the coldest meridian in the northern portion of the earth is near that passing through Washington.—We shall next consider the meteorological effects of the mountain systems of the earth. If these are placed E. and W. in the temperate zones, they will have comparatively little effect upon the meteorology of the country; but if they are placed N. and S., or cross the great aerial currents, they will then exercise a very controlling influence. Let us suppose a wind from the west, for example, blowing over the surface of a level country in the temperate zone. It will precipitate none of its moisture, because its temperature remains above that point at which the moisture can be sustained. But if the same current be deflected up the W. side of a mountain extending N. and S. into a higher and colder region, its vapor will be converted into water, or into that intermediate condition called cloud, which, descending in rain, will fertilize the W. slope of the mountain system, while on the E. side there will be a deficiency of moisture and a want of rain. This is the case with all mountains of sufficient elevation in the temperate zones, which extend in a N. and S. direction, and is particularly illustrated by the effect of the Rocky mountain system on the western part of this continent, and the Andes on that of South America. In the torrid zone, and within the region of the trade winds which blow from the east, the E. side of the mountains receives the precipitation, while the W. side is deficient in moisture. Hence the rainless portions of Peru and Central America. The Alleghany mountains are generally not of sufficient height to produce much effect in this way, and furthermore their direction is nearly parallel with that of the fertilizing or prevailing surface wind from the S. W. From the great currents of the air which we have described, it must be evident that the tendency of all disturbances in the equatorial regions must be to move westwardly, and in the temperate zones to move eastwardly. It has accordingly been found that heated and cold terms generally commence at the N. W. part of our continent, descend to the S. along the base of the Rocky mountains, and at the same time sweep eastward over the whole continent. The same is the case with great storms of rain and wind, particularly those which occur in winter, spring, and autumn. In summer these commotions are more local, and consist principally of thunder gusts, which however in every part of the United States pursue an easterly course. The explanation, or at least the approximate cause of the fall of rain and of fitful winds, is found in the unstable condition of the atmosphere produced by the gradual introduction into the lower stratum of the vapor of water. This, with the accompanying heat, tends to expand the air, and consequently to render it lighter; and when the amount of vapor becomes sufficiently great, the order of density of the strata

is in a measure reversed, and a state of tottering equilibrium is produced; the lower stratum tends on the least disturbance to break through into the colder, and to carry with it the moisture which it contains at the surface of the earth, and which, condensed by the cold in the upper regions, falls again in rain. We owe to the late Mr. Espy of this country an exposition of the effects which must flow from the bursting up of the moist stratum of air through the upper into the colder regions, and the consequent production of rain. We do not think the mere mingling of currents, as was supposed by Hutton, is at all an adequate cause, while the upward motion consequent on the instability produced by the vapor itself possesses all the characteristics of a cause both true and sufficient. It follows as a corollary from this theory, that places on the surface of the earth which superabound in moisture must be liable to great commotions of the atmosphere, as well as falls of rain. The equatorial belt of calms between the trade winds is consequently subject to rain every day, and in such quantities that fresh water may sometimes be scooped up from the surface of the ocean. Along the whole course of the Atlantic Gulf stream, from Florida to the coast of Ireland, the water possesses a temperature above that due to the latitude, and the lower stratum of air resting upon it is therefore warmer and moister than that on either side. It is consequently in a state of tottering equilibrium, and ready to burst up into the upper and colder strata, carrying with it the moisture to be condensed in torrents of rain, and drawing in around the ascending column the adjacent air, to give rise to the fearful cyclones which, commencing in the Caribbean sea, sometimes travel with unabated fury along the entire axis of the stream to the coast of Great Britain. Similar cyclones, and from a similar cause, are produced over the heated stream which flows along the E. coast of Asia, the same principle affording a simple explanation of similar tornadoes in the southern Atlantic and Pacific as well as in the Indian ocean. We have called these storms cyclones, not meaning however to adopt the hypothesis that they are simple horizontal whirlwinds, but upward and spirally in-blowing gyrations. We owe principally to the late Mr. Redfield, as is stated in the article HURRICANE, the establishment of the fact of the gyratory motion of these storms, and to Mr. Espy the proof that the principal motive force acts in a vertical direction, and consists in the rushing in and upward of the moist stratum from the surface, and the consequent evolution of the latent heat of the vapor which it contains. Indeed, it is almost impossible that an upward rushing of streams of air should take place over a small circumscribed area without their assuming a gyratory motion. When however the uprising column is of great extent, this tendency to gyrate is merged in the different directions of the various streams, and hence all the storms which visit our continent are not

of this character. Beside the class of storms which have been denominated cyclones, and which follow the general course of the Gulf stream lapping over our E. coast, there is another class to which we first alluded, which commence in the interior of the continent, and are borne along eastwardly by the westerly wind of the temperate zone. For example, after a gentle S. wind has blown for several days, particularly in autumn, winter, or spring, the surface stratum of air, beginning at the Rocky mountains and extending to the eastern seaboard, becomes abnormally moist and warm; it therefore frequently begins at the E. base of these mountains to burst upward, carrying with it into the colder strata the vapor with which it is loaded, to be precipitated in rain, giving rise to a wind from the eastward on the E. side of the storm and from the westward on the W. side. The commotion is borne eastward by the upper or prevalent westerly currents at a variable rate, from 10 to 80 m. per hour, sweeping over the whole distance from the place of its origin until it mingles with the storms of the Gulf stream. In some cases these storms extend from N. to S. over a considerable portion of the continent; but more generally the stormy condition of the atmosphere is in detached portions, each however moving eastward. In summer, the unstable condition of the atmosphere produced by the heat and moisture of the day is frequently reversed in the afternoon by thunder storms at various places, all however as a general rule moving eastward. The storm systems of Europe and Asia are similar to those of America, but more modified by the irregular direction of the mountain chains.—In this sketch we have confined ourselves for want of space to the most prominent points of the science; and in conclusion, we can only refer to the important observations collected at the national observatory, under the direction of Lieut. Maury, relative to the winds and currents of the ocean in every part of the world; to the meteorological system of the war department under Surgeon-General Lawson, and discussed by Dr. R. H. Coolidge; to the labors of the late Mr. Redfield, Mr. Espy, Prof. Loomis, Prof. Guyot, and Prof. C. F. Fin, also to those of Dr. Hare; and to the accumulation of materials relative to the North American continent at the Smithsonian institution, under the direction of Prof. Henry. Beside the systems which have been established in different states of the Union. Most of the civilized governments of Europe have also organized systems of simultaneous observations, by which as in America the progress of storms may be noted. These, with the aid of the telegraph, cannot fail to advance the science more rapidly than has ever been done at any other period of its history.

METER (Gr. *μετρον*, a measure), a word much used in combination with others to designate various measuring instruments, as thermometer, a measurer of temperature, hydrometer, measurer of the density of water, &c. When

standing alone, it is commonly understood to apply to the instruments used for measuring gas, which are described in the article Gas, or to similar contrivances for measuring the quantities of water discharged through pipes. In supplying water to cities, the want is beginning to be sensibly felt of some cheap and accurate apparatus that shall register the amount consumed by different customers, in the same way that the consumption of gas is determined; and various meters have been contrived for this purpose. But the difficulties of providing a cheap measurer, that can be depended upon for large and small quantities, delivered slowly or rapidly, are much greater when the object of the measurement is a heavy incompressible fluid, than when this is a highly elastic body like gas, which flows with little friction through pipes of different sizes and without regard to the number of bends or to differences of pressure arising from differences of elevation.—The water meters in use are of two distinct classes, one of which works in combination with compressed air, and the other without this. Of the non-atmospheric class, that of Mr. Henry Worthington of New York is perhaps the best. It consists of two cylinders placed side by side, with pistons so arranged that in working they alternately move the supply and delivery valves of the opposite cylinder. Each stroke being registered, the number of times the cylinders (the capacity of which is known) are filled and discharged is indicated. These meters are much used in New York, Boston, and other cities. Diaphragm meters of the same class are used in New York, and might be preferred to the piston and cylinder meters if it were not that the diaphragm soon wears out. Hughes's meter is a good example of this sort. A chamber is divided by a flexible water-tight diaphragm into two parts. The water entering and filling one presses the diaphragm into the other, which causes the valves to change, and the water to flow into the second chamber while it is discharged from the first. Each discharge is a measure equal to the capacity of the chamber. Meters of the character of those described are liable to get out of order from the clogging of the valves with the sediment deposited from the water, and in the case of pistons from derangement of the packing. The head of water is also more or less reduced by the force expended in moving the piston and the friction arising from passing short turns at the valves. There is also a nicety of construction necessary, which renders the instrument expensive. A third variety of this class may be called velocity meters, as they register the revolutions of a wheel which is moved by the current with a velocity proportional to its own. The wheel generally employed is that of the well known "Barker's mill," into which the water enters at the centre and passes out at the circumference nearly tangentially, imparting to the wheel a horizontal revolution. For swift currents these meters are very well adapted, but

if the flow is feeble the wheel, to turn at all, must be provided with such small apertures that they are likely to be clogged with the sediment. When faucets are left slowly running in cold weather to prevent freezing of the water, the meter may not register this flow however long it is continued; and supplies of water may thus be fraudulently obtained without any record of it. An English meter known as Seaman's is an excellent specimen of this kind. The pivot on which its wheel is hung on an inverted cup is ingeniously lubricated by oil floating on the water around it.—To the second class of meters, which may be called atmospheric, belongs Cochran's patent. The measurer is a double wedge-shaped vessel placed at the top of an air-tight case, and balanced so as to rock upon its edge. It is divided by a vertical partition into two triangular compartments. The water enters through the bottom of the case, and fills the first compartment, when it tilts and empties itself, bringing the second under the current, which repeats the operation. As the water enters the case it compresses the air contained therein, and its head is thus retained. The capacity of the air chamber is sufficiently great to prevent the water from rising so high as to interfere with the movement of the measuring buckets, each oscillation of which slides a valve, which lets out some of the water and admits a corresponding quantity of air, thus keeping up the supply. A large current is apt to cause the buckets to tilt before they are full; and if they are made proportionally large, the air chamber must also be greatly increased in size, making the machine bulky and expensive. In another form, that of Messrs. Curtis and Hoard, the water fills alternately one of a pair of upright cylinders, in the upper parts of which floats raised by the water work the valves.—A compressed air meter, recently patented by Mr. B. S. Church of New York, consists of a cylindrical wheel into which the water passes at its axis and flows into compartments on its periphery, until the weight causes them to revolve and discharge themselves, the wheel being upon a horizontal axis. A float within the wheel detains each bucket until it is exactly filled. It is made applicable to the measurement of a large current by dividing this as it enters the wheel and measuring only a part, the proportion measured being indicated by the registering apparatus. The escape of the air in bubbles together with the water, which is a fault in other atmospheric meters, is prevented by causing the current to flow under and over partitions, the effect of which is to make the bubbles rise and burst. A monitor valve is also attached to prevent the drawing of water should the air escape in sufficient quantity to disturb the measurement, in which case a fresh supply of air may be introduced by loosening a screw at the side and emptying the meter.

METHODISM. In 1729 John Wesley, a fellow of Lincoln college, Oxford, being impressed with the need of greater spirituality in religion

by an attentive perusal of the works of the Rev. William Law, particularly his "Call to a Holy Life," and also the writings of Thomas à Kempis, organized small evening meetings, with his brother Charles, a student at Oxford, Mr. Morgan, commoner of Christchurch, and Mr. Kirkham of Merton college. In a short time two or three pupils of John Wesley and one of Charles Wesley's pupils obtained the privilege of attending these meetings. They soon began to give evidence of spiritual improvement by visiting the sick in the town and the prisoners who were confined in the castle. After two years they were joined by Mr. Ingham of Queen's college, Mr. Broughton, and Mr. Hervey, and subsequently by Mr. George Whitefield of Pembroke college, then in his 18th year. At the end of 6 years their number amounted to 14. The name of Methodists was given to them, not as a term of reproach, as is generally supposed, but on account of the exact regularity of their lives, and the manner of spending their time. The society was broken up by the departure of the Wesleys for Georgia as chaplains of the colony which had been planted there. On their return to England in 1738, John Wesley began to preach in the churches of London and other places; but he met with a cold reception, and was finally debarred admission to the pulpits. Not disconcerted, however, he preached in private houses, and in the streets, cemeteries, and fields. In his brother Charles he found a faithful coadjutor, and the result of their preaching was a general awakening on the subject of religion throughout the land. So numerous became their followers that they conceived the idea of forming them into classes according to their respective localities, and appointed over each a leader who was to look after their spiritual interests in their absence. Thus originated the Methodist societies in 1739. For the government of these societies the Wesleys drew up a set of rules. The only condition of membership was "a desire to flee the wrath to come and be saved from sin." These rules prohibited "profane swearing, Sabbath-breaking, drunkenness, buying or selling spirituous liquors or drinking them, fighting, quarrelling, brother going to law with brother, the using many words in buying or selling, the buying or selling of goods that had not paid the duty, the giving or taking things on usury, or unlawful interest, uncharitable speaking, wearing of gold or costly apparel, laying up treasure on earth, borrowing without the probability of paying, or taking up goods without the probability of paying for them." These things were particularly specified, because, as the rules state, they were "most generally practised" at that time. They enjoined the observance of the following: "The doing good of every possible sort and as far as possible to all men, by giving food to the hungry, clothing the naked, visiting or helping those who were sick and in prison, by instructing, reproofing, and exhorting all they had any intercourse with; doing good especially to those who are of the

household of faith, employing them in preference to others, buying one of another, helping each other in business; attending upon all the ordinances of God, such as public worship, the ministry of the Word whether read or expounded, the supper of the Lord, family and private prayer, searching the Scriptures, and fasting or abstinence." Encouraged by the success which attended their ministry, the brothers travelled extensively throughout the kingdom, visiting the rudest and most populous districts, and everywhere producing a profound impression. It soon became necessary for them to employ lay preachers to assist them in preaching to and looking after the spiritual interests of the large societies which had been formed in different parts of the country. As the number of lay preachers increased, it became necessary for concert of action that an annual meeting should be held, which was denominated a conference, and has ever since borne that name. The first conference was held in 1747, at which John and Charles Wesley met two or three other ministers of the established church who sympathized with them, and the preachers whom they had appointed to come from various parts of the country to confer with them on the affairs of the societies. Since that time a conference has been annually held, John Wesley having presided at 47. Their deliberations, in the form of questions and answers, were afterward printed under the title, "Minutes of the several Conversations between the Rev. Mr. Wesley and others." In the early conferences various points of doctrine were discussed with reference to the adoption of a standard. Mr. Wesley adopted the articles of religion of the church of England for substance of doctrine, though he distinctly declared himself Arminian in relation to the article on predestination, understanding it in a sense not contrary to the doctrine of redemption and the possible salvation of the whole human race. The Wesleyan Methodists maintain the doctrines of original depravity, an unlimited atonement, justification by faith, and a divine assurance of acceptance with God. Since the organization of the Wesleyan church, though there have been several secessions from the body, it has gone on increasing steadily in power and influence until the present time, and is decidedly the largest and most influential of all the dissenting churches in Great Britain. The Wesleyan church has now 6 conferences, as follows: the British, including England, Wales, and Scotland; the Irish, the Australian, the Canada, the Eastern British American, and the French. In these conferences, including the numbers in foreign missions embracing continental India, northern Europe, China, Asia Minor, the South sea, and West India islands, the membership is 482,446, and the number of ministers 2,459. For the support of their missions and schools, with other benevolent agencies connected with the church, a sum little less than \$1,000,000 is contributed annually.—The more important of the Methodist denominations are treated in separate articles; see

subjoin a table of the principal minor divisions in Great Britain and British America, with their statistics for 1859:

METHODIST EPISCOPAL CHURCH, the name given to the society of Methodists in the United States. Methodism has existed in the United States since 1766, when a small number of immigrants from the Wesleyan connection in England formed themselves into a society in Philip Embury's carpenter shop on Barrack street, New York, near the present site of the city hall. The Methodist Episcopal church, however, as a separate and distinct organization, did not exist until Dec. 25, 1784, when, at the conference called for the purpose at Baltimore, the preachers assembled and assumed the title of a church. In this act they took higher ground than ever Wesley, the founder of the sect, conceived of or designed. The societies which he had formed in various parts of the British empire never had risen to the dignity of a church either in their individual or confederate capacity. Wesley himself belonged to the church of England, and, loyal to the last, he enjoined upon all his followers the same adherence. No sacraments were administered or received by them outside of the churches of the establishment. All the Methodist preachers, with the exception of the Wesleys and a few other clergymen associated with them, were unordained or lay preachers. It was from this class that Wesley sent over helpers or assistants to the societies formed in the United States, and over these he exercised exclusive jurisdiction. Of these preachers, and others who had been raised up in America, the conference of 1784 was composed. Following in the footsteps of Wesley, they recognized the Episcopal church in this country, and sought the ordinances within her pale. Episcopal churches are still standing in New York and elsewhere, at whose altars Embury, Pilmoor, Boardman, Strawbridge, Asbury, and Rankin, the earliest Methodist preachers, received the holy communion. It was not long, however, before dissatisfaction, joined with no little disaffection, arose among the preachers, particularly in the South, in regard to the ordinances. Many of the English preachers, adhering to the advice of Wesley, both in regard to state and church loyalty, unable to resist the influence and power of public opinion, had returned to England. Asbury, who had become an American in his views and feelings, and was unwilling to return with his English brethren, found it necessary, such was the opposition to English preachers, to retire from public life, and remained in the house of a friend in Delaware for two years

during the revolutionary struggle. Such being the state of things in this country, Wesley saw that an independent society was inevitable, and, that he might not lose his hold upon the American Methodists, he set himself to work to prepare for the emergency. He saw that the preachers would be satisfied with nothing short of ordination. He was a presbyter of the church of England, and having satisfied himself that presbyter and bishop were one and the same order in the original church, differing only as to their official functions, he assumed the office of bishop, and with the assistance of other presbyters of the same church he set apart and ordained the Rev. Thomas Coke, LL.D., of Oxford university, already a presbyter, as bishop of the infant church in America. After this was done, he sent Dr. Coke with his credentials of office to America, and in course of time the newly ordained bishop appeared in full canonicals at the conference of 1784 already referred to. Coke was unanimously recognized by that body as their bishop, and at once entered upon the discharge of his episcopal functions. Accompanying his credentials he had instructions from Wesley to set apart Francis Asbury to the same office, as joint bishop with him in the government of the church. Asbury was accordingly ordained, and subsequently a considerable number of preachers were set apart by ordination as deacons and elders. The letters from Wesley also gave them permission to organize a distinct church under the episcopal form of government which he had provided; this they did, and assumed the title of the "Methodist Episcopal Church in the United States of America." But almost from the very commencement there were some who did not altogether relish the idea of an episcopal form of government. They believed that it was even contrary to Wesley's design, though he doubtless conferred all the powers and prerogatives of such a government. So strong became the anti-episcopal party, that in process of time (1830) a large secession took place, and another organization was formed, denominated the "Methodist Protestant Church."—The Methodist Episcopal church, like some other churches in this country, has been thrown into excitement on the subject of slavery. In the very first conferences held, when slavery existed in the northern and middle as well as in the southern states, the subject was introduced and discussed, and resolutions were passed not only in regard to the traffic in slaves, but regulations were adopted in regard to the holding of them by the members, and requiring their emancipation at certain ages where allowed by the laws of the state. Preachers and official members were also, under certain limitations, prohibited from holding slaves. Slavery has continued to be more or less a subject of agitation to the present time; and though the laity have been allowed to hold slaves, the ministry have been prohibited from so doing except under certain circumstances, where they were held for purposes

of humanity. In 1844 the slavery question occasioned the withdrawal of the southern conferences, with one exception, from the jurisdiction of the church, and the organization of a separate and distinct church under the title of the "Methodist Episcopal Church, South." (See **METHODIST EPISCOPAL CHURCH, SOUTH.**)—The doctrines of the Methodist Episcopal church are contained in 25 articles, and are as follows: "1. There is but one living and true God, everlasting, without body or parts, of infinite power, wisdom, and goodness, the maker of all things, visible and invisible. And in unity of this Godhead, there are three persons, of one substance, power, and eternity—the Father, the Son, and the Holy Ghost. 2. The Son, who is the Word of the Father, the very and eternal God, of one substance with the Father, took man's nature in the womb of the blessed Virgin; so that two whole and perfect natures, that is to say, the Godhead and manhood, were joined together in one person, never to be divided, whereof is one Christ, very God and very man, who truly suffered, was crucified, dead, and buried, to reconcile his Father to us, and to be a sacrifice, not only for original guilt, but also for the actual sins of men. 3. Christ did truly rise again from the dead, and took again his body, with all things appertaining to the perfection of man's nature, whereafter he ascended to heaven, and there sitteth until he return to judge all men at the last day. 4. The Holy Ghost, proceeding from the Father and the Son, is of one substance, majesty, and glory with the Father and the Son, very and eternal God. 5. The Holy Scriptures contain all things necessary to salvation; so that whatsoever is not read therein, nor may be proved thereby, is not required of any man, that it should be believed as an article of faith, or be thought requisite or necessary to salvation. In the name of the Holy Scriptures we do understand those canonical books of the Old and New Testament of whose authority was never any doubt in the church. 6. The Old Testament is not contrary to the New, for both in the Old and New Testament everlasting life is offered to mankind by Christ, who is the only Mediator between God and man, being both God and man. Wherefore they are not to be heard who feign that the old fathers did look only for transitory promises. Although the law given from God by Moses, as touching ceremonies and rites, doth not bind Christians, nor ought the civil precepts thereof of necessity be received in any commonwealth, yet notwithstanding, no Christian whatsoever is free from the obedience of the commandments which are called moral. 7. Original sin standeth not in the following of Adam, as the Pelagians do vainly talk, but it is the corruption of the nature of every man that is naturally engendered of the offspring of Adam, whereby man is very far gone from original righteousness, and of his own nature inclined to evil, and that continually. 8. The condition of man after the fall of Adam is such, that he cannot turn and prepare himself, by his own natu-

ral strength and works, to faith and calling upon God; wherefore we have no power to do good works, pleasant and acceptable to God, without the grace of God by Christ preventing us, that we may have a good will, and working with us when we have that good will. 9. We are accounted righteous before God, only for the merit of our Lord and Saviour Jesus Christ by faith, and not for our own works or deserving; wherefore, that we are justified by faith only, is a most wholesome doctrine and very full of comfort. 10. Although good works, which are the fruits of faith, and follow after justification, cannot put away our sins, and endure the severity of God's judgments, yet are they pleasing and acceptable to God in Christ, and spring out of a true and lively faith, insomuch that by them a lively faith may be as evidently known as a tree is discerned by its fruit. 11. Voluntary works, beside, over, and above God's commandments, which are called works of supererogation, cannot be taught without arrogance and impiety. For by them men do declare that they do not only render to God as much as they are bound to do, but they do more for his sake than of bounden duty is required; whereas Christ saith plainly: When ye have done all that is commanded you, say, We are unprofitable servants. 12. Not every sin willingly committed after justification is the sin against the Holy Ghost, and unpardonable. Wherefore the grant of repentance is not to be denied to such as fall into sin after justification; after we have received the Holy Ghost, we may depart from grace given, and fall into sin, and by the grace of God rise again and amend our lives. And therefore they are to be condemned who say they can no more sin as long as they live here, or deny the place of forgiveness to such as truly repent. 13. The visible church of Christ is a congregation of faithful men, in which the pure word of God is preached, and the sacraments duly administered according to Christ's ordinance in all those things that of necessity are requisite to the same. 14. The Romish doctrine concerning purgatory, pardon, worshipping, and adoration as well of images as of relics, and also invocation of saints, is a fond thing vainly invented, and grounded on no warrant of Scripture, but repugnant to the Word of God. 15. It is plainly repugnant to the Word of God, and the custom of the primitive church, to have public prayers in the church, or to administer the sacraments, in a tongue not understood by the people. 16. Sacraments ordained of Christ are not only badges or tokens of Christian men's profession; but rather they are certain signs of grace, and God's good will toward us, by the which he doth work invisibly in us, and doth not only quicken, but also strengthen and confirm our faith in him. There are two sacraments ordained of Christ our Lord in the gospel; that is to say, baptism and the supper of the Lord. Those five commonly called sacraments, that is to say, confirmation, penance, orders, matrimony, and extreme unction, are

not to be counted for sacraments of the gospel, being such as have partly grown out of the corrupt following of the apostles, and partly are states of life allowed in the Scriptures, but yet have not the like nature of baptism and the Lord's supper, because they have not any visible sign or ceremony ordained of God. The sacraments were not ordained of Christ to be gazed upon, or to be carried about; but that we should duly use them. And in such only as worthily receive the same, they have a wholesome effect or operation; but they that receive them unworthily, purchase to themselves condemnation, as St. Paul saith, 1 Cor. xi. 29. 17. Baptism is not only a sign of profession, and mark of difference, whereby Christians are distinguished from others that are not baptized, but it is also a sign of regeneration or the new birth. The baptism of young children is to be retained in the church. 18. The supper of the Lord is not only a sign of the love that Christians ought to have among themselves one to the other, but rather is a sacrament of our redemption by Christ's death; insomuch that, to such as rightly, worthily, and with faith receive the same, the bread which we break is a partaking of the body of Christ, and the wine which we drink is a partaking of the blood of Christ. Transubstantiation, or the change of the substance of bread and wine in the supper of the Lord, cannot be proved by Holy Writ, but is repugnant to the plain words of Scripture, overthroweth the nature of a sacrament, and hath given occasion to many superstitions. The body of Christ is given, taken, and eaten in the supper, after a heavenly and spiritual manner. And the means whereby the body of Christ is received and eaten in the supper, is faith. The sacrament of the Lord's supper is not by Christ's ordinance reserved, carried about, lifted up, or worshipped. 19. The cup of the Lord is not to be denied to the lay people, for both the parts of the Lord's supper by Christ's ordinance and commandment ought to be administered to all Christians alike. 20. The offering of Christ, once made, is that perfect redemption, propitiation, and satisfaction for all the sins of the whole world, both original and actual, and there is none other satisfaction for sin but that alone. Wherefore the sacrifice of the mass, in the which it is commonly said that the priest doth offer Christ for the quick and the dead, to have remission of pain or guilt, is a blasphemous fable, and dangerous deceit. 21. The ministers of Christ are not commanded by God's law either to vow the state of single life or to abstain from marriage; therefore it is lawful for them, as for all other Christians, to marry at their own discretion, as they shall judge the same to serve best to godliness. 22. It is not necessary that rites and ceremonies should in all places be the same, or exactly alike; for they have been always different, and may be changed according to the diversity of countries, times, and men's manners, so that nothing be ordained against God's Word. Whosoever,

through his private judgment, willingly and purposely doth openly break the rites and ceremonies of the church to which he belongs, which are not repugnant to the Word of God and are ordained and approved by common authority, ought to be rebuked openly, that others may fear to do the like, as one that offendeth against the common order of the church, and woundeth the consciences of weak brethren. Every particular church may ordain, change, or abolish rites and ceremonies, so that all things may be done to edification. 23. The president, the congress, the general assemblies, the governors, the councils of state, as the delegates of the people, are the rulers of the United States of America, according to the division of power made to them by the constitution of the United States, and by the constitution of their respective states. And the said states are a sovereign and independent nation, and ought not to be subject to any foreign jurisdiction. 24. The riches and goods of Christians are not common, as touching the right, title, and possession of the same, as some do falsely boast. Notwithstanding, every man ought, of such things as he possesseth, liberally to give alms to the poor, according to his ability. 25. As we confess that vain and rash swearing is forbidden Christian men by our Lord Jesus Christ and James his apostle, so we judge that the Christian religion doth not prohibit, but that a man may swear when the magistrate requireth, in a cause of faith and charity, so it be done according to the prophets' teaching, 'in justice, judgment, and truth.'—The "General Rules" for the government of the church are the same as those adopted by Wesley, except the one relating to slavery, and constitute the canons of the church. The legislative authority resides in the general conference, composed of delegates from the several annual conferences, which has full power to make rules and regulations for the church under the following restrictions: "1. It shall not revoke, alter, or change the articles of religion, nor establish any new standards or rules of doctrine contrary to the existing and established standards of doctrine. 2. It shall not allow of more than one representative for every 14 members of the annual conference, nor allow of a less number than one for every 45; provided, that when there shall be in any annual conference a fraction of two thirds the number which shall be fixed for the ratio of representation, such annual conference shall be entitled to an additional delegate for such fraction; and provided also, that no conference shall be denied the privilege of two delegates. 3. It shall not change or alter any part or rule of our government, so as to do away episcopacy, or destroy the plan of the itinerant general superintendency. 4. It shall not revoke or change the general rules of the church. 5. It shall not do away the privileges of the ministers or preachers of trial by a committee, and of an appeal; neither shall it do away the privileges of the members of trial before the society, or by a committee,

and of an appeal. 6. It shall not appropriate the produce of the book concern, nor of the charter fund, to any purpose other than for the benefit of the travelling, supernumerary, superannuated, and worn-out preachers, their wives, widows, and children. Provided, nevertheless, that upon the concurrent recommendations of three fourths of all the members of the several annual conferences who shall be present and vote on such recommendation, then a majority of two thirds of the general conference succeeding shall suffice to alter any of the above restrictions excepting the first article; and also whenever such alteration or alterations shall have been first recommended by two thirds of the general conference, so soon as three fourths of the members of all the annual conferences shall have concurred as aforesaid, such alteration or alterations shall take effect." The general conference meets quadrennially, and now (1860) has subordinate to it 51 annual conferences, including the Liberia and German conferences. Each annual conference consists of all the travelling preachers, deacons, and elders of a certain portion of country, who meet under the presidency of a bishop. The main business transacted at these meetings is the admission and ordination of preachers; an examination of the character and official administration of the members composing the conference; a review of the missionary, educational, and publishing interests; and the appointment of the ministers to their several stations and circuits for the year ensuing. The territory of the annual conference is divided into presiding elders' districts, comprising several circuits and stations, in each of which there is held a quarterly conference, composed of the travelling and local ministers, the exhorters, stewards, class leaders, and superintendents of Sunday schools. The quarterly conference manages the details of local interests connected with the station or circuit; is a court of appeals in the trial of church members; grants license to preach, and recommends suitable candidates for admission into the annual conference. The episcopal office, conferred by solemn ordination, is not considered as invested with the claim and right of a third order in the ministry *de jure divino*, and therefore clothed with powers emanating directly from God, and indispensable to the existence of a church; but *de jure ecclesiastico*, the offspring of the church, and not the church of it. In connection with the episcopate, the ministry embraces the orders of elders and deacons. To be eligible to full connection in an annual conference and the office of deacon, a preacher must have travelled two years as a probationer and stood suitable examinations. He is eligible to elder's orders after two years' further service. Preachers are not authorized to baptize or administer the Lord's supper. Elders are ordained by the bishops, and may administer all the ordinances. They have charge of circuits or stations, or sometimes are placed by the bishops over several circuits or stations, called collect-

ively districts, in which case they are known as presiding elders. Stewards are persons chosen by the quarterly conferences to take charge of and disburse all funds collected for the poor, the support of the ministry, and sacramental purposes. Class leaders are appointed by the preachers; their duty is to see all the members of their respective classes once a week, and receive their contributions for church purposes. Classes consist usually of 12 persons. The number of travelling and local preachers is 18,000, and the number of members, including probationers, is 956,555. The appointments of the preachers are made every year, and no preacher is allowed to remain more than two years in one station.—Beside the domestic missions and those among the Germans, Scandinavians, French, Welsh, and Indians in the United States, the church has missions in Africa, China, India, South America, Germany, Sweden, Norway and Denmark, Bulgaria, and the Sandwich islands. The amount contributed in 1859 was \$229,145. The Sunday schools of the church contain 695,820 scholars, and the receipts of the Sunday school union for 1859 were \$11,800. There is a tract society connected with the church, which publishes a large number of tracts and books in various languages. The book concern, situated in New York, and of which there are branches at Cincinnati, Chicago, and elsewhere, is an immense establishment, constituting the largest publishing house in America. The proceeds of this establishment are, according to the "Discipline" of the church, to be divided among the several annual conferences for the support of superannuated preachers, and the widows and children of such as have died in the ministry. The official organs of the church are a quarterly review, a monthly magazine, and 10 weekly journals. The educational department of the church has kept pace with the membership, and there are now under the patronage of the several annual conferences 24 colleges, 2 bible institutes, and 120 seminaries.—The (Bethel) African Methodist Episcopal church separated from the parent association in Philadelphia in 1787, and the Zion African Methodist Episcopal church in New York in 1820, both on account of the prevailing prejudice against persons of color. The two churches number 26,746 members, and 198 travelling and 444 local preachers; and the former has a book concern and missionary society.

METHODIST EPISCOPAL CHURCH, SOUTH. The Methodist Episcopal church in the United States was composed, up to 1844, of 38 annual conferences, the ecclesiastical organization including all the slaveholding states. As early as 1773 Methodist societies were in existence in Virginia; and in 1785 Methodism was introduced into South Carolina and Georgia. It flourished in the southern states, embracing not only multitudes of the negro population, but great numbers of slaveholders in the ranks of its membership and ministry.

who were protected by express rules in the "Book of Discipline." In 1828 an eminent minister of one of the southern conferences, known to be a slaveholder, was elected by the general conference as the representative of the Methodist Episcopal church to the British conference. In all the general conferences, up to that of 1844, slaveholders among the southern delegates claimed and enjoyed a perfect equality of right and privilege with northern delegates; and it was declared by formal resolution, at the general conference of 1840, that "mere ownership of slave property, in states or territories where the laws do not admit of emancipation and permit the liberated slave to enjoy freedom, constitutes no legal barrier to the election or ordination of ministers to the various grades of office known in the ministry of the Methodist Episcopal church." At the general conference of 1844, in New York, proceedings not assuming judicial form, and unaccompanied with any regular impeachment, were instituted against the Rev. James O. Andrew, D.D., one of the bishops, a citizen of Georgia, who had married a lady possessed of slaves. These proceedings, after a protracted debate, were terminated by an act passed by a majority of the conference requiring the bishop to desist from the exercise of his episcopal functions on account of this connection with slavery. Thereupon the representatives of 13 annual conferences embraced in the slaveholding states, presented a declaration which set forth their solemn conviction that a continuance of the jurisdiction of the general conference over the annual conferences thus represented would be inconsistent with the success of the Methodist ministry in the slaveholding states. The declaration was accompanied by a formal protest against the action of the majority in Bishop Andrew's case, and this led to the adoption by the general conference of a plan of separation, according to which there was contemplated an amicable adjustment of boundary lines, and a fair division of property, should the annual conferences in the slaveholding states find it necessary to unite in an ecclesiastical connection distinct from that of the North. The church in the South and South West, in primary assemblies, and in quarterly and annual conferences, sustained the declaration of the delegates, and measures were immediately adopted for the assembling of a convention. This was held in May, 1845, at Louisville, Ky. Acting under the provisions of the plan of separation, and in pursuance of the formal instructions of the annual conferences, the convention dissolved the jurisdiction of the general conference over the conferences there represented, and created a separate ecclesiastical connection under the title of the "Methodist Episcopal Church, South." The first general conference of the organization thus formed was held at Petersburg, Va., the following year, the senior bishop of the M. E. church, Dr. Joshua Soule, having in the mean time attached himself to the southern church. A subsequent

general conference of the M. E. church of the North having repudiated the plan of separation, and refused to divide the property of the book concern, formerly held in common, suit was brought in the courts of the United States by the southern church, and a fair *pro rata* division was enforced.—The form of government in the M. E. church, South, is the same as that in its sister church of the North. There are 6 bishops and 24 annual conferences in the M. E. church, South. In 1845 the number of travelling preachers was 1,384; superannuated preachers, 90; local preachers, 2,550; white members, 330,710; colored members, 124,811; Indians, 2,978; total, 462,428. In 1859 the numbers stood: travelling preachers, 2,661; local preachers, 5,177; white members, 511,601; colored members, 197,848; Indians, 4,286; total, 721,028.—The missionary organization of the M. E. church, South, is mainly confined to the home work. This embraces missions to the plantation negroes, Germans, Indians, and among the poorer classes of the white population; and missions in China and Japan. Missions among the colored population were set on foot in 1829, chiefly through the instrumentality of the late Dr. Oapers of South Carolina. In the lapse of 30 years this department of missionary labor in the South Carolina conference has increased to 27 stations, on which are employed 35 missionaries, and embracing upward of 11,000 church members. The southern Methodist church holds that slavery, wherever established and protected by constitutional law, is a civil question, with which ecclesiastical bodies have no authority to meddle, and that the true function of the church is to preach the gospel and administer the sacraments and discipline of Christ's religion to master and slave alike. The missionary revenue of the M. E. church, South, during the first year of its separate organization, was \$68,529. For the year 1859 the amount contributed for missionary purposes was \$214,664.—The educational department comprises 21 universities and colleges for young men, 28 colleges and 27 high schools for young women, beside institutions of lower grade. Much attention is paid to Sunday schools. A publishing house was established by the general conference of 1854, in Nashville, Tenn. During the first 5 years of its operations 600,000,000 pages were published. Depositories of its publications are established in all the principal annual conferences; and a vigorous movement is on foot to endow the establishment with a large, free cash capital. There are 8 religious newspapers published weekly in different parts of the connection; one "Sunday School Journal," and one "Ladies' Magazine," monthly; and one "Quarterly Review."—The doctrines of the M. E. church, South, are the same that are taught by the other branch of the Methodist Episcopal church in this country.

METHODIST PROTESTANT CHURCH, a religious body formed in 1830 by a secession from the Methodist Episcopal church. The

primary causes of dissatisfaction were the episcopate and the organization of the conferences, whereby all authority in the church was virtually placed in the hands of the travelling preachers, to the exclusion of other ministers as well as lay members. From the very outset efforts were made by a minority in the church to secure a more general representation in the conferences, but without avail. In 1824 a meeting of the reformers was held in Baltimore, a "Union Society" was founded for the purpose of agitating the question of a change of government, similar organizations were recommended to be formed in various parts of the United States, and a periodical was established called "The Mutual Rights of the Ministers and Members of the Methodist Episcopal Church." In the spring of 1826 the Baltimore union society initiated a movement for a general convention to inquire into the expediency of making one united petition for general representation to the general conference of 1828. The convention was held in Nov. 1827, and the petition was presented, but received an unfavorable answer. The conservative portion of the church meanwhile opposed the reform movement with the utmost vigor. Union societies were everywhere condemned, and members were expelled for belonging to them in Tennessee, North Carolina, and Baltimore. The reformers now began to secede in considerable numbers. A convention met in Baltimore, Nov. 12, 1828, and drew up provisional articles of association; and on Nov. 2, 1830, another convention assembled at the same place, adopted a constitution and a book of discipline, and accepted for the new society the name of "Methodist Protestant Church." The Rev. Francis Waters, D.D., of Baltimore, was president of this convention.—The Methodist Protestant church holds the same doctrinal views as the parent body, and differs from it in few points of ecclesiastical government, though rejecting episcopacy. The general conference meets once in 7 years, and is composed of an equal number of ministers and laymen, namely, one delegate of each order from every 1,000 communicants. It has authority under certain restrictions to make such rules for the government of the church as may be necessary to carry into effect the laws of Christ; to fix the compensation and duties of travelling ministers and preachers, &c.; to devise means for raising money; and to regulate the boundaries of annual conference districts. The annual conference is composed of all the ordained itinerant ministers of the district, and has power to elect to orders, station ministers, preachers, and missionaries, make rules for defraying the expenses of their support, and fix the boundaries of circuits and stations; it chooses its own president yearly. The quarterly conference is composed of the trustees, ministers, preachers, exhorters, leaders, and stewards in the circuit of which it is the immediate official meeting. It examines the official character of its members, licenses preachers, re-

commends candidates for ordination to the annual conference, &c. There are classes, leaders, and stewards, as in the Methodist Episcopal church. The denomination has a board of foreign and domestic missions; book concerns at Baltimore, Md., and Springfield, Ohio; 7 colleges, 8 of which are for females; 2 other literary institutions; and 4 weekly periodicals. At the beginning it had 83 ministers and about 5,000 members; and at the 7th general conference (1858) there were 2,000 stationed ministers, 1,200 churches, 90,000 members, and \$1,500,000 worth of church property.

METHODIST (WESLEYAN) CONNECTION OF AMERICA, a religious body organized in 1843, and originally composed of seceders from the Methodist Episcopal church. Three questions were involved in the discussion that resulted in the secession, viz.: slavery, church government, and the sale and use of intoxicating drinks, of which the first was the most prominent and important. In Dec. 1834, an "Appeal against Slavery" was issued by a number of Methodist ministers, members of the New England and New Hampshire conferences, in which it was maintained that all slaveholding is wrong. This was soon replied to by a "Counter Appeal," signed by a number of leading ministers. In this review it was contended that slavery existed in the apostolic church, and that the apostles, instead of commanding its abolition, gave rules for its regulation. In this way the conclusion was intended to be reached that slaveholding in the M. E. church was not sinful. In the New Hampshire conference for 1835 a series of resolutions was offered, of which the following was the most objectionable to the pro-slavery party: "Resolved, that holding and treating the human species as property is a sin against God, and a violation of the inalienable rights of humanity." A motion to adopt being made, the chairman, Bishop Emory, refused to put the motion, and thereby involved in the discussion a question of church government, which became very exciting as it proceeded. The eastern conferences being over for the season, Bishops Holding and Emory, who attended them, addressed a pastoral letter "To the Ministers and Preachers of the M. E. Church within the bounds of the New England and New Hampshire Conferences." In this address they strongly condemned the anti-slavery discussion, and recommended the members and friends everywhere by all lawful and Christian means to discountenance it. The presiding elders were especially exhorted to oppose such discussion by their counsel and example. They advised the preachers, the trustees, and other members, to refuse the use of their pulpits and houses for anti-slavery meetings. At the general conference held in Cincinnati in 1836, the following resolutions were adopted: "Resolved, by the delegates of the annual conferences in general conference assembled, that they disapprove in the most unqualified sense of the two

members of the general conference who are reported to have lectured in this city recently upon and in favor of modern abolitionism. Resolved, that we are decidedly opposed to modern abolitionism, and wholly disclaim any right, wish, or intention to interfere in the civil and political relation between master and slave, as it exists in the slaveholding states of this Union." The same conference sent out a pastoral address, in which similar views were expressed. Soon after this conference a strong opposition began to be manifested toward leading anti-slavery ministers and members of the church. The advice of the general conference was construed as law, for the violation of which ministers and members were liable to be tried and expelled. It was also decided by the highest authorities, that the ordination vows of ministers bound them implicitly to follow the advice of their superiors. Under these decisions many were tried, suspended, or excommunicated; and at the New York conference in 1838, 5 preachers were deprived of their sacred function. The breach grew wider every day, and the conflict more undisguised. Two points in the final issue were now clear and well understood by both parties. It was contended by one party that slaveholding was wrong in all circumstances, and that slaveholders ought not to be admitted to the church; by the other party, that slaveholding as it existed in the M. E. church was not sinful, and that no one ought to be subject to church discipline for merely owning or holding slaves. On the subject of church government the anti-slavery party contended that they had a right to speak, preach, write, and act against slavery; that it was a moral question which involved religious truth and duty, and with their views silence would be a crime; and they added, that the interests of the church were best advanced by yielding allegiance only to the truth and right. On the other hand, the authorities of the church insisted that Methodist conferences and churches have no right to act against slavery in their organic capacities; and they appealed in behalf of their own authority to the vows of ordination, which promised a willing obedience on the part of the candidate. The other side replied that at the time of their ordination they did not understand the pledge in the broad sense in which their opponents urged it. The natural result of these dissensions appeared in the withdrawal of numerous local societies, and a growing disaffection toward the M. E. church on the part of the anti-slavery members. These were almost all temperance men, and the position of the church with regard to the manufacture and sale of intoxicating drinks afforded them additional ground of complaint. One of the rules of the church was as follows: "If any member of our society retail or give away spirituous liquors, and any thing disorderly be transacted under his roof on this account, the preacher who has the oversight of the circuit shall proceed against him as in the case of other immoralities." As

the offence contemplated in this rule consisted wholly of disorderly conduct, the simple traffic was held to be constructively authorized; and this view was pressed with such force that in 1840, in the height of the discussion, the general conference struck the rule from the "Book of Discipline." This, however, did not check the assaults, because other rules were retained that covered the same ground. One such was the following: "No elder, deacon, or preacher among us shall distil or vend spirituous liquors without forfeiting his official standing." This was interpreted as permitting the traffic to lay members, and it was the fact that there were many members of the church in different parts of the country engaged in it, against whom the church did not or would not proceed. As these facts were examined and debated, many became convinced that it was morally wrong to remain in visible Christian fellowship with a church that tolerated such practices. While these events were transpiring, new causes of complaint arose under the question of church government, and open disobedience showed itself. In 1841, a church in Lowell, Mass., refused to receive the minister sent by the bishop to take charge of them. For this offence the preacher, by a public proclamation, pronounced them all out of the church, and at the next session of the New England conference the presiding bishop sustained the action of the preacher. At the same conference, a member offered a resolution which simply affirmed that slaveholding is a sin, but the bishop refused to entertain it. In Nov. 1842, Orange Scott, Jotham Horton, and La Roy Sunderland publicly proclaimed themselves withdrawn from the M. E. church; and one of their number, Mr. Scott, issued a weekly journal, the "True Wesleyan," devoted to the interests of the new movement. New secessions followed, and a convention preliminary to a permanent organization of the protesting elements was held in Andover, Mass., Feb. 1, 1843. At this convention principles were discussed and a call for a general convention issued, which was held at Utica, N. Y., May 31, 1843; when the "Wesleyan Methodist Connection of America" was organized, and articles of faith and a form of discipline were adopted.—The religious doctrines of this body are substantially the same as those of the M. E. church. Of their rules of morality the two following are distinctive: 1. Their rule in regard to slavery excludes from church membership and Christian fellowship all who buy or sell men, women, or children, with an intention to enslave or hold them as slaves, or claim that it is right to do so. 2. Their rule in regard to intoxicating drinks equally excludes all who manufacture, buy, sell, or use intoxicating liquors, or in any way intentionally and knowingly aid others so to do, unless for mechanical, chemical, or medicinal purposes. The government of the Wesleyan Methodist Connection is democratic, each church having power to act for itself, and ministerial equality is a funda-

mental idea with them. They style their organization a "connection," or union of churches; but in speaking of the whole in their relation to each other, they say the "Wesleyan Methodist churches." There is a quarterly conference with every pastoral charge (which may consist of one or more churches), composed of all its officers. It has power to license preachers, and to recommend the licentiates to the yearly conferences. The latter are composed of all the ministers within their several geographical bounds, together with an equal number of laymen. They have power to elect elders and to ordain them, and to make rules for their own government. The general conference is composed of an equal number of ministers and laymen elected at the several yearly conferences. It has power to make rules for the whole connection. The whole number of members in 1858 was 20,000; of ministers engaged in the regular work, 800. The connection has two colleges under its control, viz.: Michigan union college, at Leoni, Jackson co., Mich., and the Illinois institute, at Wheaton, Du Page co., Ill.

METHODIUS AND CYRILLUS, two Greek missionaries of the 9th century, natives of Thessalonica, and supposed to have been brothers. Methodius had in early life acquired celebrity as a painter in Rome; afterward he went to Constantinople, and entered a monastery of Basiliana. Having been sent to preach the gospel to the Bulgarians, Bogoris their king, who had heard of his skill with the pencil, desired him to paint a picture more terrible than any he had ever seen. Methodius painted one of the "Last Judgment," which so affected Bogoris that he immediately embraced Christianity; and the conversion of the king was quickly followed by that of the entire nation. Accompanied by Cyrillus, Methodius then proceeded to the Slavic tribes beyond the Danube, and became the founder of the Pannonian church, of which he was the first bishop. This event took place about 868. The two brothers also brought with them the arts of civilization, invented a Slavic alphabet, and translated for their converts the Sacred Scriptures and the liturgy. Some authorities assert that Methodius likewise converted the Bohemians and their duke Borziwoi. The time of the death of these brothers is uncertain. Methodius was canonized, and his festival is celebrated in the Greek church on May 11.

METONYMY (Gr. *μετα*, denoting change, and *ονομα*, a name), in rhetoric, a trope by which one word is substituted for another, to which it stands in a certain evident relation. The substance may be named for the quality, the cause for the effect, the precedent for the consequent, or the reverse. Thus, "gray hairs" may stand for "old age," the name of Virgil for that of his writings, the "head" for the "intellect," and the "olive branch" for "peace."

METRE, the French elemental unit of length, upon which the other measures of capacity and weight in what is called the metrical system are

based. (See *LITRE* and *GRAMME*.) In the absence of any other natural standard, it was determined at the period of the first revolution to adopt an aliquot part of the terrestrial meridian; and in 1795 a provisional measure was adopted, supposed to be the ten millionth of the quadrant, or the forty millionth of the whole circumference, measured over the poles. By the law of 1799 this was slightly changed, though probably rendered less correct, in accordance with the results of the measurements of an arc of the meridian between the parallels of Dunkirk and Barcelona, undertaken for this purpose by Delambre and Méchain. (See *EARTH*.) The difference, however, is only about $\frac{1}{1000}$ of the length, or less in a single metre than $\frac{1}{1000}$ of an inch. The length of the metre as thus fixed is equal to 8.2808992 English feet, or very nearly 89.87079 English inches. For expressing the decimal multiples of the metre, and also of the units of the other measures, prefixes derived from the Greek were adopted, viz.: *deca*, meaning 10 times; *hecto*, 100 times; *kilo*, 1,000 times; and *myria*, 10,000 times. For the decimal parts the prefixes were from the Latin, viz.: *deci*, $\frac{1}{10}$; *centi*, $\frac{1}{100}$; and *milli*, $\frac{1}{1000}$. The unit of square measure is a square decametre, or 100 square metres, and is called an *are*. It is equal to 119.6088 square yards, or nearly $\frac{1}{4}$ of an English acre.

METTERNICH, CLEMENS WENZEL NEPOMUK LOTHAR, prince, an Austrian statesman, born in Coblenz, May 15, 1778, died in Vienna, June 11, 1859. His ancestors had held a high position in the German empire since the 15th century, members of the family having repeatedly filled the archbishoprics of Treves and Mentz, and the Metternichs possessing the largest interest in livings and stalls connected with all the German sees and in the election of bishops. He continued the career of his father, who had obtained some reputation as a diplomatist and as the associate of Kaunitz, studied at Strasbourg, where he had for his fellow student Benjamin Constant, and made his first public appearance as master of ceremonies at the coronation of Leopold II. (1790). Subsequently he spent some time in Mentz in the study of jurisprudence; made a journey to England, became Austrian ambassador at the Hague, and married in 1795 the granddaughter and heiress of Kaunitz, whose large domains, added to his own patrimony, which included extensive estates in Bohemia, Moravia, on the lake of Constance, and on the Rhine, gave him a foremost position among the wealthiest landholders of Germany, and in connection with his high rank, varied attainments, and accomplishments, led to his rapid advancement. He first came into prominent notice at the congress of Rastadt (1797-'9) as the representative of the Westphalian nobility; after which he accompanied Count Stadion to St. Petersburg, and officiated as ambassador in Dresden (1801). As early as 1804 he had already obtained the reputation of the most refined of the Austrian diplomatists, and was sent

to Berlin in order to prevail upon the king of Prussia to join the new coalition against Napoleon. In 1806 he was selected for the mission at the court of the Tuileries. The French emperor received him with the remark: "You are very young to represent so powerful a monarchy." "Your majesty was not older at Austerlitz," replied Metternich. The historian Schlosser, in his narrative of that period, says: "It was a great gain to Austria that Metternich was sent as ambassador to Paris instead of the miserable Philipp Cobenzl, who had so scandalously suffered himself to be deceived in 1805, and had lulled the emperor of Austria into a ruinous security respecting the views, plans, and preparations of the French, till it was too late. The importance to which Metternich rose in public affairs was afterward very salutary for Austria, for to him indisputably belongs the glory, if it be a glory, of being in some measure a match for Talleyrand." In 1807 he concluded at Fontainebleau the convention by which Braunau was restored to Austria, and the Isonzo river made the boundary of Italy. In 1809, on the outbreak of the war between Austria and France, Metternich had some difficulty in obtaining his passports, and was only enabled to leave shortly before the battle of Wagram (July 5 and 6). He joined the emperor Francis in Hungary, and was appointed to succeed Count Stadion as minister of foreign affairs. In 1810 he conducted the negotiations with Champigny in regard to the marriage of the French emperor with the Austrian archduchess, and subsequently escorted Maria Louisa to Paris. Metternich, however, never ceased to watch the ambitious designs of Napoleon, and kept himself in constant communication with the English and Russian governments. Napoleon, smarting under his great reverses in Russia, and embittered by what he called the intrigues of Metternich and Stadion, openly accused the former in his interview with him in Dresden (June 27, 1813) of conspiring against him, while professing to conclude with him a treaty of peace; he even went so far as to ask him how much he had received from England for his treacherous conduct, at which remark Metternich grew pale. Fain, in his "Manuscript of 1813," gives a graphic account of this interview. In the excitement of the conversation, Napoleon's hat was dropped, but he was compelled to pick it up himself, Metternich passing it several times in walking up and down the room, without noticing it, as he would have done on all other occasions. Schlosser says: "Napoleon, however, immediately repented having forgotten himself in so inexcusable a manner toward the representative of his father-in-law, having laid himself so open, and having mortally offended this Jesuitical courtier." Metternich, on the other hand, entirely succeeded in his object, and on the night of the very same day when he made his hypocritical proposals of peace to Napoleon, a formal treaty was concluded at Reichenbach, signed by Stadion, Nes-

selrode, and Hardenberg, by which Austria engaged to declare war against France, in case the conditions which were to be proposed at Prague should not be accepted. This treaty was for a long time kept secret. The formal declaration of war by Austria against France was drawn up by Metternich's order, probably by Gentz (Aug. 11), and the quadruple alliance was concluded by him at Töplitz, Sept. 9. Metternich's great influence in this war soon became apparent. The kings of Bavaria and Würtemberg were induced to forsake Napoleon by a secret provision made through Metternich that they should be protected against popular disturbances, and should receive additional possessions. Metternich was rewarded by the Austrian emperor for his zeal by the hereditary dignity of a prince of the empire, which was conferred on him on the eve of the memorable battle of Leipsic. He took a leading part in all subsequent conferences and treaties. To Napoleon's proposal of an armistice (Jan. 19, 1814), which he dictated to La Bessardière in a special letter to Metternich, the Austrian minister replied on Jan. 29, that "he was convinced it would not lead to any thing." The French emperor ridiculed this letter, and said: "Metternich fancies he controls the destinies of Europe, while he is under the control of all the other powers." When the congress of Vienna was opened, he was unanimously chosen to preside over its deliberations; and from that time until the revolution of 1848 he exercised a remarkable ascendancy over the affairs of Austria and Europe. He was strenuously opposed to the French revolution of 1830. Being at Carlsbad with Count Nesselrode when the news of it reached him, he remarked to the French ambassador to Vienna: "The emperor holds in entire abhorrence that which has just taken place in France. His profound conviction is that the present order of things cannot last." After the death of Francis (1835) Metternich remained in possession of his office as chancellor and prime minister, and accompanied the new emperor Ferdinand, in Sept. 1835, to Töplitz and Prague, where an interview took place between that monarch and those of Russia and Prussia. In 1840 and 1841, during the complication of the oriental question, he exerted his influence in favor of the maintenance of peace abroad, while at home, by his iron rule, he prepared the way for the revolution which terminated his power (March 13, 1848). Barely escaping with his life from the exasperation of the people, he fled through Holland to England, where he remained till Nov. 1849. He next removed to Brussels, and in 1851 the reaction had progressed sufficiently to enable him to return to Vienna. On his way thither, he visited his estate on the Johannisberg, which had been presented to him by the emperor in 1816, but which during the revolutionary movements in Germany in 1848-'9 had been taken from his control. While there he received the visit of the king of Prus-

sia, and a similar honor was conferred upon him by the present emperor of Austria, who again visited the faithful servant of his dynasty almost immediately on his arrival in Vienna (June, 1851). Without resuming public office, he continued until his death to exercise great influence in political affairs, and is said to have advised the maintenance of the most absolute rule over the Austrian possessions in Italy. He died about a fortnight before the battle of Solferino. The prince was fond of letters and art; and in his letters to Alexander von Humboldt, for whom he entertained a high regard and admiration, he remarks that he had missed his vocation, and that his inclination would have led him rather to the sphere of science than to that of diplomacy. In addition to his Austrian titles, he had been created by the king of Naples duke of Portella, with a pension of 60,000 Neapolitan ducats, had also been made a Spanish duke, and honors and presents had been showered upon him by all European potentates. His first wife died in 1825, having borne him two daughters—Leontine, married in 1835 to Count Maurice Sándor, and Herminie, honorary canoness of the chapter of the ladies of Savoy of Vienna. His second wife, whom he married in 1827, the beautiful baroness of Leykam, who was made countess of Beilstein, and who died in 1829, became the mother of his eldest son and heir, Richard, the present Prince Metternich, who married in 1856 a daughter of Count Sándor, and who, after officiating as ambassador in Dresden and as attaché to the ministry of foreign affairs during the war of 1859, became soon after the peace of Villafranca (July 11, 1859) ambassador at the court of Napoleon III. By his third wife, Countess Melanie of Zichy-Ferraris, whom he married in 1831, and who died in 1854, Metternich had a daughter, Melanie, who married in 1853 Count Joseph Zichy, and two sons, Paul and Lothar, the elder of whom is an officer in the Austrian army.

METTRAI, a French village, 5 m. from Tours, containing a celebrated establishment for the reformation of juvenile offenders, supported by voluntary donations and annual subscriptions, in which, since its foundation in 1839, over 2,000 children have been trained, chiefly by agricultural labor. Lord Brougham has called it one of the glories of France. (See **DEMETZ**, **FRÉDÉRIC AUGUSTE**, vol. vi. p. 361.)

METZ, a fortified city of France, capital of the department of Moselle, at the confluence of the Seille and Moselle, 245 m. E. by N. from Paris; pop. of the arrondissement in 1856, 178,465, and of the city, 44,176, exclusive of the garrison of 10,000 men. It is one of the strongest fortresses of France, ranking next after Strasbourg. The city is surrounded by a regular system of fortifications, and entered by 9 gates furnished with drawbridges. The most important works, which were commenced by Vauban and Belle-Isle and completed by Cormontaigne, are the fort of Belle-Croix, commanding the E. part of the city from the Porte des Allemands

to the river; the fort of La Double Couronne, protecting the southern part; and the Redoute du Pâté, which forms an island connected with the interior of the city by a subterranean gallery. The esplanade in the centre of the city is a beautiful promenade; the quarter on the right side of the Moselle contains many steep and narrow streets. Among the principal public buildings are the arsenal, containing upward of 80,000 muskets; the cathedral; the church of Notre Dame de la Ronde and of the abbey of St. Vincent, both religious edifices of great antiquity; the military hospital, the hall of justice, and the public library. Beside many Roman Catholic churches and convents, it contains a Calvinist church and several synagogues. It has also a celebrated artillery and engineering school. The arrondissement has manufactories of woollen goods, hosiery, plush, embroidery, beer, tiles, nails, &c., the annual value of the products of which amounts to nearly \$2,000,000. —Metz is of great antiquity, and was known to the Romans under the name of Divodorum, changed subsequently to that of Mediomatrici, having been the capital of that portion of Belgic Gaul; in the 5th century it was called Mettis or Metia. It became celebrated as the capital of Austrasia, which was afterward called the kingdom of Metz, and which in the middle of the 9th century assumed the name of Lorraine. In the early part of the 10th century Metz fell into the power of Henry the Fowler of Germany, but recovered its independence in the 11th, and became famous for its commerce with Germany, its brilliant society, and its love of letters and art. In 1552 it was united with France.

METZU, **GABRIEL**, a Dutch painter, born in Leyden in 1615, died there in 1658, or according to some authorities in 1669. In his youth he established himself in Amsterdam, where he rose to eminence as a *genre* painter. In his pictures the mere imitation of nature is carried to perfection. In drawing and perspective he was unsurpassed, as also in harmonious tone, in richness of color, and in chiaroscuro. He painted a few portraits, including one of Admiral Van Tromp now in the Louvre. His pictures are rare out of Holland, and bring very high prices.

MEULEN, **ANTOINE FRANÇOIS VAN DER**, a French artist, born in Brussels in 1634, died in Paris in 1690. In early youth he became a pupil of Peter Snayers, a painter of battles, and his own efforts in this department of the art recommended him to Le Brun, then the chief authority in art criticism in Paris, by whose suggestion he was invited thither to paint campaign scenes in the life of Louis XIV. He passed the remainder of his life in Paris, where he was highly esteemed not merely as a painter of battles, but of hunting scenes, cavalcades, and the like. One of his finest series of battle pieces is that formerly kept in the chateau of Marly representing the campaigns of Louis in Flanders.

MEURSIUS, or **DE MEUR**, **JOHANNES**, the

elder, a Dutch scholar and antiquary, born in Lordun, near the Hague, in 1579, died in Sorøe, Denmark, Sept. 20, 1689. He was appointed tutor to the sons of the grand pensionary Barneveldt, and accompanied them to the principal courts of Europe. In 1610 he was made professor of history at Leyden, and in the following year professor of Greek. Subsequently the states of Holland conferred on him the title of historiographer, and many other honors; but on the execution of his patron Barneveldt, he was subjected to persecution, and in 1625 accepted the appointment of professor of history in the university of Sorøe. He wrote numerous monographs on Greek and Roman antiquities, reprinted in great part in the *Thesaurus* of Graevius and Gronovius (18 vols. fol., Leyden, 1697-1702); *Res Belgicae* (1612); *Glossarium Græco-Barbarum* (1614); and *Historia Danica* (Copenhagen, 1680). His collected works fill 12 volumes folio (Florence, 1741-'63).

MEURTHE, a N. E. department of France, in the old province of Lorraine, bounded N. by Moselle, E. by Bas-Rhin, S. by Vosges, and W. by Meuse; area, 2,858 sq. m.; pop. in 1856, 424,873. It is remarkable for the beauty of its scenery, the fertility of its soil, and the variety of its productions. The surface is diversified and covered to a great extent with dense forests. The principal mountains are the Vosges, which range along the E. frontier. The chief rivers are the Meurthe, Moselle, Seille, and Sarre.

MEUSE, a N. E. department of France, in the old province of Lorraine, bounded N. by Ardennes and Luxemburg, E. by Moselle and Meurthe, S. by Vosges, and W. by Haute-Marne, Marne, and Ardennes; area, 2,405 sq. m.; pop. in 1856, 305,727. The Faucilles mountains traverse it from S. E. to N. W., and send off numerous ramifications. The chief rivers are the Meuse, Aisne, Aire, and Orne. Cotton and iron are manufactured. Capital, Bar-le-Duc.

MEUSE (anc. *Mosa*; Dutch, *Maas*; Fl. *Maeze*), a river which rises in the department of Haute-Marne in France, and, flowing N. through those of Vosges, Meuse, and Ardennes, enters Belgium near Charlemont. At Namur it changes its course toward the N. E., which direction it keeps till near its entrance into Holland, when it turns again toward the N., then flows N. W., and finally W. A little below Gorkum it divides into two branches, one of which takes the name of Merwe, and, after again dividing and forming the arms the island of Ysselmonde, falls into the German ocean amid shoals and quicksands; while the other branch, which flows more to the S., and likewise subdivides into two smaller streams, discharges its waters by these channels into different parts of the same sea. The delta of the Meuse is larger than that of any other European river. Its principal tributaries are, in France, the Mouzon, the Vair, and the Chiers; in Belgium, the Sambre, the Lesse, and the Ourthe; in Holland, the Waal, the

Leck, and the Yssel. The chief cities on its banks are Verdun, Sedan, and Charlemont, in France; Namur and Liège, in Belgium; Maastricht, Willemstadt, and Rotterdam, in Holland. The length of the river is over 550 m., and it is navigable to Verdun, 480 m. from the sea.

MEW, or SEA MEW, a name given in Great Britain to some of the smaller gulls, and especially to the common European species (*Larus canus*, Linn.), called also winter mew.

MEXIAS, one of the channels by which the Ogobay river of central Africa reaches the ocean, 56 m. S. of the equator, in long. 8° 47' E. It was formerly supposed to be an independent river, but the explorations of M. Du Chaillu have shown that it communicates by innumerable offsets not only with the Ogobay, but also with Nazareth and Fernand-Vaz rivers. It is narrow, but during the rainy season discharges such a volume of water that the current is felt for several miles out to sea, and it is sometimes fresh at its mouth at high tide. (See OGObay.)

MEXIOAN PICTURE WRITING, a name given to a system of hieroglyphics in use among the semi-civilized nations of Central America and Mexico, previous to the discovery of America by Columbus. Careful recent investigations have shown that no single term can adequately characterize the system, or rather systems (for there was more than one), and that among the nations which anciently had their seat near Palenque, there existed a probably pure hieroglyphical system; while among the nations of Mexico, in the valley of Anahuac, as also among the affiliated families of San Salvador and Nicaragua, a less perfect or mixed system prevailed, which was composed of condensed pictures, and conventional or derivative representations of things, having a hieroglyphical character and a clear phonetic value. The capacity of even this less perfect or mixed system was considerable. By means of it the Mexicans compendiously recorded their history, composed their rituals and civil and religious calendars, recorded titles to property and the judgments of courts, assessed taxes or tribute, defined genealogies, &c. When Cortes landed, full accounts of him, his men, equipments, and, so far as he indicated them by word or action, of his purposes, were thus recorded and sent to Montezuma. The Spaniards were not a little surprised at the capacity of a system of representation obviously so imperfect; and the ecclesiastics who followed in the train of the conquering army, animated by a zeal not surpassed by the martial spirit of the military chiefs, readily conceived the purpose of using this system among nations whom it would have been a hopeless task to attempt to instruct in the Spanish language and alphabet. All the influential part of the native population in Mexico, the officers of the empire and the entire sacerdotal body, were thoroughly instructed in their hieroglyphical system; and the Catholic propagandists used their utmost exertions to acquaint themselves with it, and adapt it to the purpose of convert-

ing the natives. The first attempt in this direction, or perhaps the first use of pictorial representations, out of which this adaptation gradually grew, was within 8 or 9 years after the capture of Mexico, by Testera of Bayonne, brother of the chamberlain of Francis I. According to the historian Torquemada, "not being able to learn the language of the Indians as quickly as he wished, and impatient of delay, he adopted a new mode of preaching by means of an interpreter, taking with him the mysteries of the faith painted on a cloth, which the interpreters explained to the Indians as directed by the servant of the Lord. And thus he converted vast numbers, availing himself greatly of the representations or pictures which he carried with him." Testera afterward became commissary-general of the Indies, and his followers, the celebrated Sahagun, Motolinia, and Peter of Ghent, as also the Franciscans generally, adopted his example of using pictures, more or less borrowed from the Mexicans, in their teachings. In the provinces near Mexico, as soon as the Franciscans commenced this adaptation, the interpreters, and numbers of the natives employed as missionaries, lent themselves to extend its scope; and Motolinia in his MS. informs us that he was literally overwhelmed with Indians who presented their confessions to him in figures or paintings after their mode of representation. Valdez in 1579, and Torquemada nearly a century after the conquest, received similar confessions; indeed, in their time, this system of recording confessions was preferred to alphabetical writing, even by Indians who were perfectly well versed in the latter. And there still exist, in the museum of Mexico, as elsewhere, several kinds of catechetical compositions, under a more or less advanced adaptation of the native system, some of them approaching so nearly to absolute native originals, dating beyond the conquest, as only to be distinguished from them by the materials on which they are painted. They exist of all dates, from the arrival of Testera in 1529 up to 1600, the time when Juan Baptista, still making use of the paintings, wrote his work entitled "Hieroglyphics of Conversation, in which, by means of paint and figures, the natives are taught to desire heaven."—Many manuscripts or paintings, having their origin with the early priests and missionaries, and some of them even painted on paper of the magney, such as was in use before the discovery, have found their way to Europe, and into private and public collections, where they have been confounded with the paintings and manuscripts of true Mexican origin, and of earlier date. Of course, we cannot be surprised to find in this class of MSS. those confirmations of Christian doctrine and the Hebrew Scriptures, allusions to the creation, the fall, the deluge, and the birth and death of Christ, which have so profoundly impressed the minds of superficial investigators, and which have been variously adduced in support of the hypothesis of the

unity of the human race, descent of the American aborigines from Asiatic or Jewish tribes, a universal primitive religion, &c. They have led also to equally erroneous conclusions in the minds of inquirers equally superficial, but with different preoccupations, who rashly condemn all the Mexican MSS. in existence as monkish impostures, and of a date subsequent to the Spanish conquest. The truth however is, that there is a certain number of paintings and MSS. in existence, of undoubted aboriginal origin, historical and ritual in character, and dating back beyond the discovery of the continent. Some of the historical MSS. were continued in the spirit and style of the ancient system, by competent native hands, after the conquest, and contain the Indian version of that event. There are others of equally unquestionable ancient date, but generally of a religious or mythological character, which there is reason to believe have been changed in copies, or altered in the originals, with a view to conform with priestly teachings, and illustrate the dogmas of the church. And finally there is that large class of MSS., originating with Testera, and perfected by his followers, which have already been described. This latter class have a special value, inasmuch as we may reach through the various stages of their development, and their gradual approximation to the true Mexican system, with which it must have been the aim of their authors to make them exactly conform, the principles of that aboriginal system, and the rules of its application. Under this view they merit a fuller notice and explanation. They seem to have been of three kinds: 1, those of Testera and the early Franciscans, which were simple paintings, more or less adapted to Indian conventionalisms in their style of execution; 2, those of a mixed kind, in which some simple paintings were preserved, largely illustrated by arbitrary native and other figures, which for lack of a better term might be called hieroglyphics; and 3, those in phonetic characters or representations, forming a complete adaptation of the Mexican system. The mixed MSS. were only those of Testera, touched up by the natives, with proper and other names in phonetic rebuses, with sometimes a sign illustrating the action represented in the painting. The proper manner in which these paintings should be made led to serious quarrels among the monastic orders. One of these MSS. belonging to M. Aubin of Paris (who has made the graphic system of the Mexicans a special study, and with singular success), bears the name and is annotated by Sahagun. It was also in possession of the unfortunate Boturini, who describes it as consisting of "eleven leaves in figures and ciphers, by the Fray Bernardino de Sahagun: a very curious thing, by means of which the Indians learned with ease the mysteries of our faith." The 3d class of Christian or post-Mexican paintings were phonetic, and are correctly described by Torquemada, who, according to Ixtlilxochitl, was the first who suc-

ceeded in interpreting the pictures and poems of the Indians. After speaking of the mode in which some Indians learned the *Pater Noster*, he adds: "Others changed the Latin into words in their own language which resembled them in sound, representing them not by letters but by the things themselves signified; for they had no letters except pictures, and it was by them that they understood each other. This will be more clear by an example. The word in their language most nearly representing *Pater* being *pantli*, the name of a kind of small flag, they put this flag for *Pater*. In place of *noster*, a word resembling their *nochtli*, they paint a *tuna* (cactus) fig, the name of which, *nochtli*, recalls the Latin *noster*; and so they go on to the end of the prayer. By a similar process and like characters they wrote down what they wished to learn by heart. This was during the first period of their conversion, for now (between 1592 and 1614) they no longer require to use these ancient characters." This passage, which gives the true key to the Mexican writing, accords with what he elsewhere says of a class of Totonac monks who were employed "to put in good style and to write in figures the discourses which the aboriginal pontiffs pronounced in public." Sahagun and other authors also assure us that the ancients had school books "containing poems in the ancient characters." In some of the paintings designed to record the Lord's prayer, the representation of two altars stands for daily bread. Now, daily bread rendered literally in Nahuatl or Mexican is *momotlae*, while an altar in the same language is *momotli*. In other paintings the same phrase or term is represented by the figure of a roll of bread and the sun—a sun among the Indians being equivalent to a day. We even find Spanish phoneticism in paintings of this kind. Thus in the title *Ave Maria*, we observe a bird, *ave* in Spanish, standing for its first part. Phonetic signs were sometimes sustained through whole prayers, without the slightest resort to ideography; and this fact gives us some idea of the capabilities of the pure Mexican system. Such is the case with a *Pater Noster* preserved in the museum of Mexico, which throws great light on the ancient paintings. The manner in which the title, *Pater Noster*, is rendered, may serve to illustrate the whole:

(*Pa-te nocht-te*, or *Pa-tell nocht-tell*.)

First is the figure of a little flag, or *pantli* in Nahuatl, the root of which is *pan* or *pa*; second is the sign of stone, *tell*, root *te*, the whole making syllabically *Pa-te* for *Pater*, the *r* being wanting in the Mexican language. Next we have the sign of the fruit of the cactus, *nochtli*, root *noch*, and that of stone, *tell*, root *te*, as before, making *nocht-te* for *noster*. The whole is therefore the nearest possible approach to the

Latin, represented by Mexican figures of exact and unmistakable phonetic value. A general comparison of the ancient and positively Mexican paintings leaves no doubt that this mode of representation, by syllabic phonetics, in which the roots of words only were to be understood by the figures or sounded in reading, was the mode universally accepted, more or less mixed up with ideographic signs and simple pictures. —Most of the Mexican MSS. which have been preserved belong to that class of mixed compositions which borrow the aid of writing and drawing, similar to our geographical charts, our plans, and certain engravings with legends, in which the figures and places are accompanied by their proper names, and sometimes by an explanatory text. In general, on a ground or in a topographical frame, at the side, above, or in the middle of compartments indicating the year, and sometimes the day, the paintings display the principal events intended to be recorded, represented in a conventional style; as, for example, the head in profile, and the eye turned toward the spectator; men in reddish brown, and women in yellow, &c.—particulars which we find among the Egyptians. Behind the bust or head of a man, or on the generic symbol of town or village, figurative signs express the name of the person or place. In these figurative signs consists for the most part what is called Mexican writing. These are the symbols which Humboldt recognizes as "capable of being read," and which "consisted in joining together signs which stood for sounds." The rest of the picture is usually composed of chronological signs, of easily determinable value, and of a topography and iconography frequently very rude, among which we should as little look for Mexican art as for that of Raphael in our heraldic figures or playing cards.—In the historical and administrative documents of a superior order, the figurative writing, constantly phonetic, is no longer ideographic except in rare instances where the phonetic system fails. But it by no means follows that the same records should be alike, or in other words, that different paintings relating the same history should coincide in their signs, even when phonetically exactly alike. For instance, the name of Itzcoatl, the 4th king of Mexico, is expressed in some of the MSS. by the figure of a serpent (*coatl*), with its back crested with knives or arrow heads of obsidian (*itzli*); the whole, *Itzcoatl*. In other paintings, however, it is written syllabically as follows: figure of an arrow head, *itzli*, root *itz*; figure of a vase, *comitl*, root *co*; figure or sign of water, *atl*; the whole, *Itz-co-atl*. The documents of this class, in which the syllabic writing predominates, are generally land registers, tribute rolls, judgments of courts, genealogies, &c., and were continued long after the conquest, and for the use of the Spanish administrations were often accompanied by literal translations from which alone a very full dictionary of the Mexican signs might be constructed. In numeration and chronology the Mexican system was

exact and ample. Most of the historical paintings are simple annals, but some give more specific dates, down to the day of the month on which the event recorded took place. The most striking and to the uneducated eye the most interesting of the Mexican paintings are the ritual calendars, and schemes of judicial astrology, which make up the greater part of Lord Kingsborough's published collection. Excepting the designations of the days, these seem to be purely figurative or symbolical, intended only for the use of the priests and diviners, and possessed of an esoteric significance. They are valuable only in connection with the study of Mexican mythology and the Aztec religion and superstitions.—And here it may be observed, that although all the painted historical records and civil and ritual calendars on skins or paper of the maguey which have been brought from the tropical regions of this continent, are loosely called Mexican, yet there is a wide distinction to be drawn between those found in Mexico and those obtained in Central America. Of the latter unfortunately but few examples are known to exist. The so called Dresden MS., published by Lord Kingsborough, is perhaps the only perfect example of this kind in Europe. Its figures and signs coincide with those sculptured on the monuments of Palenque, Yucatan, and Copan, and identify it as the work of the same people. It has but slight resemblance to the Mexican MSS. already discussed, and seems to mark a far higher development of the graphic art. So far as they can be made out, the elements of the Central American or Toltecan system were few and very exact in their application, not admitting of that variation which would naturally result from the caprice or varying individual conceptions and tastes of those working under the system of Mexico. We discover in it no proper representations of things, except as pictures illustrative of what may be called the text of the MS. in which they are used, or in miniature in the text when employed as signs or characters, having a fixed and constant value, or modified only by the addition of arbitrary signs, like the points in oriental writings. It is undoubted that such MSS. as that of Dresden were in common use in all parts of Central America occupied by the Tzendal or Toltecan stock at the time of the discovery, and that the existing aboriginal population of that country is chiefly made up of the descendants of the authors of the system then in use, who were equally the builders of the monuments to which uncritical investigators would assign a foreign origin and high antiquity. If so, then, as the hieroglyphics of Egypt could only be interpreted through the Coptic, the modern form of the ancient Egyptian tongue, so the hieroglyphics of Central America can only be made intelligible, and their phonetic value obtained, through the medium of the Maya, Quiché, Kachiquel, and other existing languages, themselves only dialects of a common mother tongue, to which has been given the name of Tzendal.

The Mexican system seems to have been intermediate between the rude picture records and mnemonic symbolism of the North American Indians, and the hieroglyphical and probably purely phonetic system of Central America, but at the same time of higher development and capacity than that of New Granada and Peru. It was evidently in an infant but progressive state at the time of the conquest.

MEXICO, a federal republic in North America, extending from lat. 15° to 32° N., and from long. 86° to 117° W., bounded by the United States, the gulf of Mexico, the Caribbean sea which washes part of Yucatan, the British territory of Balize, the Central American republic of Guatemala, and the Pacific ocean. The dividing line between the United States and Mexico, according to the treaty of Dec. 30, 1853, known as the Mesilla or Gadsden treaty, is as follows: "Beginning in the gulf of Mexico, three leagues from land, opposite the mouth of the Rio Grande, as provided in the 5th article of the treaty of Guadalupe Hidalgo, thence, as defined in said article, up the middle of that river, to the point where the parallel of $31^{\circ} 47'$ N. latitude crosses the same; thence due W. 100 miles; thence S. to the parallel of $31^{\circ} 20'$ N. latitude; thence along the said parallel of $31^{\circ} 20'$ to the 111th meridian of longitude W. of Greenwich; thence in a straight line to a point on the Colorado river 20 English miles below the junction of the Gila and Colorado rivers; thence up the middle of said river Colorado until it intersects the present line between the United States and Mexico; and thence to the Pacific by the line separating the two Californias, which, as laid down in the treaty of Guadalupe, is as follows: "A straight line drawn from the middle of the Rio Gila, where it unites with the Colorado, to a point on the coast of the Pacific ocean, distant one marine league due S. of the southernmost point of the port of San Diego, according to the plan of said port" attached to the treaty. The extreme length of the republic, N. W. and S. E. measured on a straight line from the southern extremity of the state of Chiapa to the northern limit of Lower California, within one league of the bay of San Diego, is upward of 2,000 m. and its extreme breadth, in lat. 26° N., over 1,100 m. Its coasts extend over 1,600 m. on the gulf of Mexico and the Caribbean sea, and upward of 4,200 m. on the Pacific ocean and the gulf of California. Its N. frontier is 1,792 m. in length, and its southern 532 m.; and its breadth at Tehuantepec is 130 m. Before the treaty of Guadalupe Hidalgo, and the Mesilla or Gadsden treaty, Mexico comprised an area of 1,690,817 sq. m.; but, by the first mentioned treaty, her territory was reduced 897,650 m., and in pursuance of the second 26,185, leaving its present total area 766,482 sq. m.—The republic of Mexico is divided, under the constitution of 1857, into 23 states, one district, and one territory. The population is stated by the latest Mexican authorities to be 8,283,000, distributed as follows:

States.	Area in square miles.	Population.	Average population to square mile.	Capitals of States.	Population of Capitals.

In the aggregate, the frontier states have but 637,106 inhabitants, and, including Sinaloa and Durango, their population is only 958,625; yet these six states and one territory have an area of 400,000 sq. m., or more than one half of the entire Mexican republic. The population may be classified as follows: of pure European blood, $\frac{1}{3}$, or 1,656,620; of the native or indigenous race, $\frac{1}{3}$, or 2,208,824; of mixed European and indigenous blood, $\frac{1}{3}$, or 4,417,644. On an average the annual increase of the population of the republic may be estimated at 144,000.—The sea coast of Mexico is irregular, and deeply indented by numerous bays and gulfs. Its geological structure is peculiar. The great Cordillera of the Andes, which traverses the whole of South America from its southernmost limit, is exceedingly depressed at the isthmus of Panama, and again at Tehuantepec, where it serves merely to form a barrier between the Pacific and Atlantic. But, as soon as this massive chain enters the broader portion of North America, it divides into two gigantic arms, one to the E. and along the shores of the gulf, and the other to the W. along the shores of the Pacific, which support between them a continuous lofty platform or table-land, crossed and intersected by innumerable sierras, some of which rise to the height of 17,000 feet above the level of the sea. This table-land extends from the isthmus of Tehuantepec as far N. as lat. 42°, and, narrow at the S., expands toward the N. W. till about the latitude of the city of Mexico, where it attains its greatest breadth of 860 m.; and there also it is the highest. It is generally level, except where detached mountains occur, and its S. part is divided into 4 portions or distinct plateaus, surrounded by hills from 500 to 1,000 feet high. In one of these, the plain of Tenochtitlan, surrounded by a wall of porphyritic mountains, stands the city of Mexico. On the E. side the table-land declines, until, at the Rio Grande, on entering Texas, it has reached the

level of that river; and on the N. toward El Paso, and along the frontier of Chihuahua and Sonora, its general elevation has become only some 3,000 to 4,000 feet. The following lines of elevation will illustrate the peculiar topography of Mexico:

A remarkable series of active volcanoes occurs along a parallel about 16 m. S. of the city of Mexico. Tuxtla is the most eastern of them, near the Mexican gulf, next to which stands the snow-shrouded cone of Orizaba, with a crater which shines like a star in the night. Popocatepetl, the highest mountain in Mexico, lies still further W., and, with the peaks of Iztaccihuatl and Toluca, united by a chain of smaller volcanoes, forms a volcanic circle around the city of Mexico and its lake. On the W. slope of the table-land, about 70 m. from the Pacific, is the volcanic cone of Jorullo, which rose suddenly above the plain, on the night of Sept. 29, 1759, and is the highest of 6 mountains which have been thrown up in this part of the table-land since the middle of the last century. The cone

of Colima, the last of this series, stands insulated in the plain of that name, between the W. declivity of the plateau and the Pacific. The

following table shows the height above the sea of the principal mountains, those marked with an asterisk being volcanoes:

Mountains.	States.	Elevation.	Mountains.	States.	Elevation.
Popocatepetl*	Mexico.....	17,716 ft.	Soconusco*	Chiapa.....	7,874 ft.
Pico de Orizaba*	Vera Cruz.....	17,872	Jesus Maria.....	Chihuahua.....	6,275
Iztaccihuatl*	Mexico.....	14,786	Tabacotes.....	Do.....	7,79
Cofre de Perote.....	Vera Cruz.....	18,410	Cerro del Mercado.....	Durango.....	7,923

—The rivers which flow through the Mexican territory are divided into three classes, viz.: those which flow into the Pacific ocean, those

which fall into the gulf of Mexico, and those which terminate in lakes and lagoons, as shown in the following table:

Rivers.	States through which they flow.	Length in miles.	Termination.
Rio Grande.....	New Mexico, Chihuahua, Coahuila, and Tamaulipas.....	1,427	Gulf of Mexico.
Panuco.....	San Luis Potosi and Tamaulipas.....	286	Do.
Alvarado.....	Oajaca and Vera Cruz.....	161	Do.
Coatzacoalco.....	Tehuantepec.....	145	Do.
Grijalva.....	Chiapa and Tabasco.....	344	Do.
Usumacinta.....	Do.....	341	Do.
Rio Yaqui.....	Sonora.....	367	Gulf of California.
Rio Mayo.....	Do.....	208	Do.
Fuerte.....	Between Sonora and Sinaloa.....	273	Do.
Culiacan.....	Sinaloa.....	156	Do.
Mezquital.....	Durango and Jalisco.....	299	Pacific Ocean.
Santiago.....	Jalisco.....	261	Do.
Balsas.....	Mexico, Guerrero, and Michoacan.....	419	Do.
Ures.....	Sonora.....	411	Lake of Sonora.
Lerma.....	Mexico and Michoacan.....	282	Lake of Chapala.

—Mexico is naturally divided into three regions, or superficial strata, viz., the *tierras calientes*, *tierras templadas*, and *tierras frias*. The *tierras calientes*, or hot lands, embrace chiefly that portion of the territory lying on the borders of the Atlantic and Pacific, and extend up the slope of the respective ranges to an elevation of between 8,000 and 4,000 feet. This division, however, is not confined exclusively to the coast, for it also includes such portions of the interior as do not exceed that elevation, and where there is heat and moisture enough to produce the fruits of the tropics. The *tierras templadas*, or temperate regions, comprise all that greater portion of the republic having an elevation of between 4,000 and 8,000 feet, embracing the whole of the vast plateau stretched between the mountains of the gulf and those of the Pacific slope. This is the characteristic region of Mexico, and includes within its limits all the great centres of population of the republic. The *tierras frias*, or cold lands, comprise the mountainous districts rising above the level of the *tierras templadas* up to the limit of constant snow. Between these elevations of 8,000 and 8,000 feet a considerable Indian population, hardy and independent, is to be found upon the sierras, and also many of the most extensive mining districts. Though Mexico extends into both the temperate and the torrid zones, its climate depends less upon latitude than upon elevation. In general, the republic, with the exception of the coast and a few other places, enjoys an even and temperate climate, free from the extremes of heat and cold, in consequence of which most of the hills in the cold regions are covered with trees, which never lose their

foliage, and often remind the traveller of the beautiful scenery of the valleys of Switzerland. In the *tierras calientes* we are struck by the groves of mimosas, liquid amber, palms, and other gigantic plants characteristic of tropical vegetation; and finally, in the *tierras templadas*, by the enormous haciendas, many of which are of such extent as to be lost to the sight in the horizon with which they blend. The Mexicans make two grand divisions of the 12 months into the “dry season” and the “rainy season.” The latter commences about June and lasts usually 4 months, and the dry season comprises the remainder of the year. The soil of Mexico, with the exception of a few tracts which are not sufficiently irrigated, is exuberantly fertile, and in some places the yield of maize is from 250 to 300 fold.—Mexico produces precious stones, as the ruby, amethyst, topaz, opal, garnets, agate, and chalcedony. The great wealth of the country, according to developments up to the present day, consists in its mines. It is true that the capital and labor, both foreign and domestic, employed there, have been chiefly devoted to the production of the precious metals; and, though under a new order of things agriculture and manufactures may receive greater attention, still the abundance of minerals is so great that its mines must always constitute the leading interest. The minerals of Mexico are silver, gold, copper, iron, zinc, lead, antimony, arsenic, sulphur, cobalt, &c. The mines of gold and silver only have been worked extensively, and silver forms the principal currency of the country and the great article of export. In treating of Mexico there is no subject so unsatisfactory or bewildering as

that which relates to the products of her mines. Humboldt, who wrote in 1808, gives some valuable statistics of mining operations in Mexico previous to that period. He states the total amount of silver raised from the Mexican mines from the conquest in 1521 to 1808, according to the official returns, at \$1,767,952,000; and adding one seventh for unregistered silver, he makes the grand total \$2,097,952,000. Ward gives the total coinage from 1733 to 1826, according to government returns, as \$1,488,658,611. A writer in "Hunt's Merchant's Magazine" (New York, Aug. 1856) estimates the total product of the Mexican mines from the conquest of Cortes to the present time at nearly \$12,000,000,000. The ancient Mexicans, properly speaking, had no coin. The conquerors introduced it, and coining dates from the building of a mint in the city of Mexico in 1535. For many years after the invasion pieces of gold and silver were stamped by officials of the crown, which constituted them a circulating medium.

The coinage of money in Mexico presents two great epochs: first, from the establishment of a mint in the city of Mexico up to the independence; and second, from the independence to the present date. The first period affords three subdivisions, viz.: *moneda macuquina*, or irregular coins; *moneda columnaria*, or pillar coin; and *moneda de busto*, or bust coin. The first was so called owing to its irregular form and weight, and was stamped by means of a hammer, with a cross, two lions, and two columns on one side, and on the reverse with the name of the reigning king. The second received the name of "pillar" from presenting on one side the arms of Spain, supported by the pillars of Hercules. This was the first coin struck in the mint according to the rules of art. The third, or "bust coin," bears the effigy of the last king who ruled Mexico. The following statement of the coinage of Mexico, from the conquest down to and including the year 1856, is from official data furnished by the *ministerio de fomento*:

Mints.	Silver.	Gold.	Copper.	Total.
Mexico	\$2,097,952,000	\$78,447,480	\$8,483,788	\$2,211,084,468
Chihuahua	107	954,802	\$8,428	11,800,518
Culiacan	280	2,804,410	9,641,940
Durango	67	2,831,918	22,673,878
Guadalajara	43	661,317	\$2,989	28,770,140
Guadalupe y Calvo	48	2,311,104	..	4,375,082
Guanajuato	28	10,855,830	333,821,646
San Luis Potosi	701	\$8,617	37,326,778
Sombrerete	40	1,881,248
Tlalpa	16	202,444	1,162,000
Zacatecas	38	107,940	160,083,442
Total	\$2,634,115,679	\$96,802,642	\$6,781,728	\$2,838,745,861

The yearly coinage of the mints of Mexico increased in steady progression from the time of the establishment of the first mint up to the year 1805, when the highest amount was reached, being for that year \$27,000,000. The total coinage of the mints of Mexico from the war of independence to 1856 is as follows:

1802	1	26	1848	\$18,162,567
1803	1	24	1841	12,475,082
1804	1	73	1842	12,800,206
1805	1	68	1843	12,075,088
1806	1	71	1844	12,671,280
1807	16	91	1845	14,236,717
1808	31	48	1846	15,414,433
1809	15	88	1847	17,080,115
1810	11	71	1848	19,203,088
1811	31	90	1849	19,386,570
1812	11	69	1850	19,389,320
1813	25	79	1851	17,481,934
1814	15	65	1852	18,190,514
1815	31	67	1853	17,028,921
1816	11	82	1854	17,269,946
1817	11	69	1855	17,563,678
1818	11	67	1856	19,205,646
Total	12,425,085		Total	\$478,892,614

The following is the coinage of the different mints of Mexico in the years 1855 and 1856:

Mints.	Gold.	Silver.	Total.
Culiacan	\$144,368	\$737,988	\$882,356
Chihuahua	17,536	475,500	493,036
Durango	73,647	609,171	682,818
Mexico	156,388	4,013,349	4,169,737
Guanajuato	844,380	4,696,900	5,541,280
Guadalajara	10,388	633,682	644,070
San Luis Potosi	1,849,796	1,849,796
Zacatecas	2,619,800	2,619,800
Aggregate	\$964,322	\$12,687,265	\$13,651,587

In 1856.

Mints.	Gold.	Silver.	Total.
Culiacan	\$278,088	\$665,546	\$943,634
Chihuahua	10,084	400,000	410,084
Durango	57,072	552,662	609,734
Mexico	164,297	4,401,798	4,566,095
Guanajuato	479,478	4,304,634	4,784,112
Guadalajara	5,388	588,486	593,874
San Luis Potosi	2,676,000	2,676,000
Zacatecas	2,676,000	2,676,000
Aggregate	\$985,912	\$12,203,281	\$13,209,193

The ancient tribunal of commerce in 1805 estimated the amount of money in circulation in New Spain at something more than \$78,000,000, which, being compared with the population, gave an average of \$14 per head. Taking this estimate as a basis, and also taking into consideration the prosperity of mining operations ever since that date, with the general improvement in the circumstances of a class who were formerly in misery, it is not an overestimate to say that the amount in circulation in 1856-'7, notwithstanding the great annual exportation, exceeded \$100,000,000. Although this sum is undoubtedly sufficient for all the interior wants of Mexico, considering the small extent to which operations are carried on in agriculture, manufactures, and commerce, the fact that the greater portion of it is in few hands, with the want of confidence and absence of banks of issue, makes it comparatively useless. The legal exportation of specie from all parts of the republic, for the year 1856, was as follows:

Acapulco.....	\$32,485	Tabasco.....	\$52,841
Campeche.....	180,807	Vera Cruz.....	8,185,028
Guaymas.....	118,626	Camargo.....	7,000
Matamoras.....	795,945	Mier.....	6,869
Mazatlan.....	1,381,089	Piedras Negras.....	114
Manzanillo.....	581,469	Paso del Norte.....	7,643
San Blas.....	845,267	Zapaluta.....	7,540
Sinaloa.....	10,320		
Tampico.....	4,415,523	Total.....	\$16,479,018

From the conquest of Mexico, in 1521, to the year of independence, 1821, a period of three centuries, the business of mining was in most respects brought to such perfection that during the space of 85 years in which it may be said this branch of labor has been open to the science of foreign nations, no very material improvement has been effected on the old system, except in the introduction of steam engines for clearing deep mines of water. The kings of Spain held the mines of Mexico as royal property, but any citizen of the country was allowed to work them by paying over to the royal treasury one fifth of the product thereof. The government of Mexico, after she obtained her independence, decreed the mines to be public property, but placed certain restrictions on the miners, and required a small percentage on their products to be paid into the national treasury. This tax is now relinquished, and any citizen or foreigner can, by the right of discovery, denounce or record a mine, and obtain the right to work a certain number of *varas* free of all tribute. It is believed that the laws of the *mineria* of Mexico are well calculated to develop the mines and favor the miners, and it is doubtful whether any material improvement can be made on the present code. Statistics relating to this subject previous to the revolution are, doubtless, more complete and trustworthy than such as we have since; yet those that come to us from the former period give a general idea only of the vast product of silver in Mexico, and while we have the same general means of judging of their unfailing richness since that epoch, the official data are much more imperfect owing to the revolutions which have almost constantly prevailed, the occasional destruction of government records, and more than all else, the general system of smuggling which has, during this unhappy state of affairs, been carried on over the frontiers, and through nearly all the ports in the country.—Mexico unites the vegetation of North and South America, but its flora resembles more nearly that of the latter. By reason of its peculiar geological structure, and its variations of climate and temperature according to elevation, it presents an immense variety of indigenous productions; and scarcely a plant exists on the globe which cannot be grown in some part of the country. Whole provinces on the table-land produce alpine plants, oaks, chestnuts, and pines, spontaneously. Rice, Indian corn, the banana, the sugar cane, tobacco, coffee, jalap, and cacao are cultivated. The caoutchouc tree, milk tree, and vanilla plant abound. The *rhizophora copallinum*, from which the copal of Mexico is produced, logwood, mahog-

any, and many other large timber trees grow in the forests. There are large fields of the American aloe, from which a fermented liquor called *pulque* is prepared. From this plant the ancient Mexicans made their cordage and their paper. The *opuntia cochinellifera*, which nourishes the cochineal insect, is indigenous to Mexico, and long before the conquest was cultivated for the valuable dye which the insect affords. There are other dye woods, medicinal plants, and trees that furnish precious gums in great variety.—The various quadrupeds which minister to the use of man for food or other purposes abound in such quantities that, owing either to the smallness of population, or to the little use made by the great mass of the people of meat for their daily food, there is perhaps no other country in the world where cattle are so cheap as in Mexico. Wild animals, valuable as articles of food, are found in equal abundance throughout the country. The number of horses and asses is enormous. The same may be said of mules, which are commonly employed for carriages, for agricultural labor, and for working in the mines. Wild horses, said to be of Arabian extraction, wander in vast herds over the interior provinces, and also horned cattle and sheep, all from imported stock; the gigantic wild stag, with branching horns, is famous for its beauty and swiftness. The tapir, the jaguar, and the wolf are common. Fish, in immense numbers and of great variety, are found both on the coasts of the gulf and in the Pacific, as well as in the lakes and streams of the interior. The tortoise-shell fishery on the coast of Yucatan, and the pearl fisheries on the coast of Lower California, yield abundantly, and are of great importance. Of birds fit for use there are above 70 different sorts in the republic. Of the birds which are distinguished by the beauty of their plumage and the sweetness of their song, there are, according to Cavigero, about 50 or 60 different species. Many birds are peculiar to Mexico, and others, as the eagle and hawk, are superior to the same species in Europe. The turkey is found wild; there are more than 20 different species of ducks, and geese and other fowls abound. Bees are successfully raised for their wax rather than their honey. The silkworm was introduced by the Spaniards soon after the conquest, and large plantations of mulberry trees were set out, but most of them were destroyed by the Indians in the 18th century to avoid the exactions to which the silk trade exposed them.—The native population of Mexico is composed of 6 races: 1, whites, descended from the Spanish settlers; 2, Indians; 3, negroes; 4, mestizoes, the offspring of whites and Indians; 5, mulattoes; 6, zamboes or chinos, the offspring of negroes and Indians. The foreigners in the country are principally Spaniards, Germans, French, English, and Americans from the United States. The negroes are computed at only 6,000. At the present day all the races are on a footing of perfect legal and political equality.

The Indians of Mexico do not differ materially in appearance from those of other parts of America. They have the copper color, straight black hair, small beard, high cheek bones, and other prominent characteristics of the red race. They are habitually grave, melancholy, and taciturn. In the imitative and mechanical arts they show great skill, and they possess a remarkable fondness for flowers, in arranging which for ornament they display much elegance of taste. Their social condition is for the most part one of extreme poverty. The men are well made and muscular, and are simple and temperate in their habits, living almost exclusively upon vegetables. They are chiefly occupied in agricultural pursuits. The white Mexican is commonly described as proud, indolent, abstemious, much addicted to gambling, and much under the influence of the priests. Of the mixed races, the mestizoes are mild and amiable, while the mulattoes are distinguished by the violence of their passions, their superior energy and activity, and their volubility. In the northern states there are powerful tribes of savage Indians, who live by rapine, and are constantly at war with the civilized Mexicans.—The number of landed estates of the republic is 13,000, the value of which is estimated at \$720,000,000, and town property at \$685,000,000. This gives a total valuation of real estate at \$1,355,000,000, or an average of \$163.50 per head. The agricultural productions of Mexico are still limited to the absolute necessities for the consumption of its inhabitants, and the extent of ground under tillage is not equal to more than one eighth of the whole arable land of the republic. The principal productions are maize, beans, and chile (which three articles, in general, constitute the only food used by the poorer class), wheat, barley, rice, potatoes, peas, lentils, American aloe, nopal, sugar cane, cacao, coffee, cotton, tobacco, pepper, anise, vanilla, sarsaparilla, and all kinds of fruits and horticultural productions; to which may be added indigo, cochineal, wax, and silk, of which two last articles large quantities are already produced in the states of Michoacan, Jalisco, and Guanajuato. As regards the annual value of the agricultural produce of Mexico, the statistics are so limited and unsatisfactory that it is impossible to arrive at any thing like a correct estimate. The best information which we possess is contained in an account presented in the year 1817, by Don José Maria Quiroz, at that time secretary to the chamber of commerce in Vera Cruz, according to whom the total value of agricultural produce in New Spain amounted then to \$138,850,121 annually, including \$4,997,496 as the amount of produce exported; which sum, when compared with the then existing population of 5,810,005, gives an average of \$24 per head. This estimate, however, cannot serve as a basis to arrive at its present value, considering the progress, even though slow, which has been made since in this and in all the other branches of industry. For want of better data, we may take the

amount of population, and calculating the quantity of agricultural produce necessary for the support of each person at \$25 per annum, or about 7 cents per day, the result is a yearly produce equal in value to \$197,000,000; and if to this be added the amount consumed by cattle, the production of cotton (70,000 quintals annually), cochineal (625,000 lbs.), silk, wax, and many other articles, and \$40,000,000 as the value of the increase of domestic animals, and of their natural produce, such as milk, eggs, tallow, &c., the annual value of agricultural productions throughout the whole country may be safely estimated at \$260,000,000. The cultivation of sugar cane, as much from its enormous yield as from its good quality, is of the greatest importance. In Mexico, Puebla, Vera Cruz, Michoacan, Tabasco, Oajaca, Chiapa, Yucatan, Sonora, and Lower California, there are large plantations. In the 6 first mentioned states 40,000,000 lbs. of sugar are manufactured yearly. Coffee has been produced of very good quality in the districts of Hutlen and Tessic, in the state of Jalisco; but the best is found in Cuernavaca, Colima, and some parts of the state of Vera Cruz; it is equal in quality to the best produced in any part of the world. Tobacco is cultivated with success in many parts of the republic, and is destined to become an article of extensive exportation, particularly that produced in Tabasco, called *tabaco de corral*. Indigo is found wild in great quantities in many parts of Oajaca, Tabasco, Yucatan, Chiapa, Michoacan, and Colima. That produced in the last mentioned place is considered to be of a superior quality. Rice is cultivated to a considerable extent in the tierras calientes, in damp and marshy situations, and yields from 40 to 60 per cent. It is destined to become one of the principal objects of agricultural industry, as the soil and climate of many localities are peculiarly adapted to its growth. Cacao of excellent quality is found in Tabasco and Soconusco, in the state of Chiapa, and other places in the states on that side of the gulf, and, perhaps, yields the best in the world. Flax and hemp are successfully cultivated; the latter particularly in the southern districts of Michoacan, where it grows even spontaneously. The product is very large, and the fabrics made from it are highly approved. Throughout the cotton-growing districts of the United States the cotton plant is of annual growth; frost destroys it, and the planter is obliged to renew the seed for every crop. But in the tierras calientes of Mexico the tree propagates itself, and the laborers are only required to keep the fields free of useless vegetation. The production, however, is very limited, not at all meeting the wants of the factories in the republic, and probably does not exceed in the aggregate over 25,000 bales of 400 lbs. each per annum. A sample of beautiful cotton, called "silk cotton," said to have been raised by Col. David Randon, Fort Bent co., Texas, from seed obtained in Mexico, was received in New Orleans in 1858. It resem-

bles that grown in Texas from seed brought from Nicaragua, near Leon, and which for fineness and silkiness, as well as tenacity of fibre and tenuity of thread, has never been surpassed. About 250 lbs. of this cotton can be picked by one hand in a day, whereas of the sea island not more than 30 lbs. can be picked. The seed is planted about Sept. 1, and always yields a sure crop, which can be raised at one half the expense attendant upon its culture in the Mississippi valley. The cultivation of the cochineal has always been of the greatest importance in the state of Oajaca. The amount and value of the crop in that state alone, in the years 1854 and 1855, were as follows :

Years.	Cochineal necatillo, lbs.	Grana blanca, lbs.	Grassilla, lbs.	Value.
1854.....	150,525	632,625	2,450	\$523,433
1855.....	145,050	500,525	1,550	459,709
Total	295,575	1,133,150	4,000	\$983,142

The vanilla bean is cultivated on a few plantations in Oajaca, and also grows there, as in many other parts of the coast, spontaneously, in large quantities. In the state of Vera Cruz it has become one of the principal articles of exportation, with a gradual increase of shipments annually. Although the cultivation of the vine might be a most important branch of industry, it is at present almost confined to the town of Parras in the state of Coahuila, where excellent wine has been produced. In Chihuahua and Sonora, however, wine and brandy are produced from the grape; and in Durango, Zacatecas, and Jalisco, a liquor called *mescal* is manufactured to a large extent. Maize is cultivated as well in the hot regions as in the temperate and cold. It is very largely consumed in the country, both for human food and for fattening animals. In the hot regions it produces from 250 to 300 grains for each one planted, and in a district near the capital as many as 600. In many parts of the country two crops are gathered annually; and in fact

there are frequent instances on the gulf coast of three harvests on the same ground in one year. In the fields of wheat and maize is sown the *frijol*, or black bean, which is most extensively consumed in Mexico, and is as much a national dish with the Mexicans as the potato is with the Irish. Wheat is cultivated on all the central table-lands. The best is found in Atlisco, in the state of Puebla, and in the fertile valleys between Queretaro and Guanajuato, called Bajio, where it yields 60 to 1. In some parts of the state of Sonora, and other sections of the republic, the yield has been computed by good authorities at nearly double the amount. Barley is also extensively cultivated on all the central table-lands, with equally abundant harvests. There is a very great consumption of it throughout the country, as it is one of the principal articles of forage used by the muleteers and wagoners for the animals of the immense transportation trains. Beside almost every variety of fruit trees to be found in other parts of the world, Mexico possesses an inexhaustible source of wealth in the natural products of her forests, which furnish abundantly a supply of the several woods employed in ship building and other mechanical arts, either for works of use or fancy. Every branch of agricultural industry is susceptible of augmentation and improvement, and if a proper spirit of enterprise could be awakened in its inhabitants, Mexico might become one of the most prosperous countries on the American continent.—The manufacture of sugar is extensively carried on by private individuals, who commonly have mills of a very primitive and imperfect character on the plantations where the sugar is grown. In some places, however, the modern improvements in machinery have been introduced. Aguardiente is also distilled on private farms. Wines and brandies are made in considerable quantities in the states of Coahuila and Chihuahua, and might be produced in many other parts of the republic. The manufacture of cotton cloths and threads is shown in the following table:

States.	Number of factories.	Number of power looms.	Number of hand looms.	Number of spindles in operation.	Yearly consumption of cotton, quntals.	Factory prices per piece, \$7 yds. by 1-4	Cost of cotton at factory per quintal.
Coahuila.....	1	40	..	1,800	1,800	\$21
Durango.....	5	117	..	4,536	4,761	\$5 00	12 25 26
Guanajuato.....	1	900	950	4 50 to 6 00	20 " 22
Jalisco.....	5	427	..	18,852	24,250	4 50 " 5 50	22 " 24
Mexico.....	8	650	564	23,650	21,400	3 02 " 4 00	22 " 24

Colima.....	2
Total.....	47	3,001	894	121,254	124,698

The total cost of buildings and machinery was \$7,872,951; the number of hands employed, 10,000; and the annual expenses, \$1,261,000. Although some of the finest cloths are manufactured in these, the principal product consists of thread and brown cottons, or *mantas*. Ac-

cording to the statistics published by the *Ministerio de fomento* in 1854, there were 7,274,777 lbs. of the former and 872,224 pieces of the latter made at these factories in the preceding year. A large quantity also of tapes, gloves, stockings, and other similar articles, are manu-

factured in Mexico. In addition to the numerous hand looms in various parts, by which common cloth, frieze, serges, druggets, blankets, &c., are manufactured, there are now (1860) 8 large woollen manufactories in the federal district, and in the states of Mexico, Queretaro, Zacatecas, and Durango, at which fine cloths, cassimeres, carpetings, baize, flannels, and other stuffs are produced, equal to any imported. In the capital, and in Puebla and Guadalajara, there are above 70 hand machines for spinning and twisting silk. The whole quantity twisted in Mexico in a year may be estimated at 40,000 lbs. There are 8 paper manufactories in the district of Mexico and the states of Puebla and Jalisco, which produce not only sufficient to supply the presses of the republic, but considerable quantities for other uses. Cotton and the fibres of the maguey are the principal materials used. In the states of Durango, Mexico, Michoacan, and Oajaca, there are various iron foundries, where the best quality of iron is manufactured. Mexican bar and tire iron is preferred to the English for quality. There are no certain data by which to ascertain the present annual value of the manufactures of all kinds; but with due allowance for the great progress which has been made in this branch of national wealth, we may safely put down the sum total at \$90,000,000 or \$100,000,000.—The total annual value of the foreign imports into the republic of Mexico was estimated by Sr. Lerdo de Tejada in 1856 at \$26,000,000, and of exports at \$28,000,000. The general prevalence of contraband trade, particularly along the Pacific coast, renders it difficult however to ascertain the total importation of merchandise or exportation of specie; and the entire commerce, legal and illegal, may be considered nearly if not quite double the above amount. The difference in favor of the exports, as given above, is attributed to the large sums annually exported by the government in payment of interest on the foreign debt, and to the large amounts exported by foreigners who, after some residence in Mexico, return to their homes. The imports consist chiefly of cotton, linen, woollen, and silk fabrics, as well as cotton and silk in their raw state, brandies, wines, liquors, oil, earthenware, glass, quicksilver, iron, guns, steel, tin, hardware, watches, jewelry, paper, machinery, wax, cocoa, carriages, furniture, musical instruments, books, and other articles of minor importance. Of the \$28,000,000 of exports, about \$23,000,000 or \$23,000,000 are of gold and silver, in coin and bars. The remainder is made up of cochineal, vanilla, tobacco, coffee, jalap, sarsaparilla, American aloe, flax, copper, hides, tallow, timber, cattle, logwood, indigo, cocoa, pepper, salt, tortoise shell, pearls, mother-of-pearl, meat and fish salted, rice, beans, hats, woollen fabrics, biscuit, fruit, sugar, preserves, and other articles of small value. In 1856 the duties on cotton, linen, silk, and woollen manufactures of all kinds were reduced 15 to 40 per cent.; on iron, ironmongery, and hardware, 33½ to 40; cutlery, 37½ to 40; jew-

elry, 40; wine, 30; glass, 40; and miscellaneous articles, as paper, cinnamon, butter, pictures, &c., 10 to 60 per cent. The amount of imports from different countries, as estimated by Sr. Lerdo de Tejada, is as follows:

Great Britain.....	\$12,500,000
United States.....	4,500,000
France.....	4,500,000
Germany.....	1,860,000
Spain.....	700,000
Belgium.....	300,000
Sardinia.....	90,000
Guatemala, Ecuador, New Granada, Venezuela, and Chili.....	250,000
Island of Cuba.....	600,000
India and China.....	700,000
Total.....	\$26,000,000

The exports of Mexico are mainly shipped, in the shape of silver coin and bullion, direct to England, by the British steamers which touch at Vera Cruz and Tampico, and by British men-of-war from the Pacific coast. The rest goes chiefly to the United States. The total commerce, imports and exports, is distributed nearly as follows:

Exchanges with England.....	\$33,400,000
“ “ United States (1858).....	8,700,000
“ “ France.....	5,500,000
“ “ Germany.....	2,000,000
“ “ Spain.....	1,200,000
“ “ Belgium.....	400,000
“ “ Sardinia.....	100,000
“ “ Guatemala, Ecuador, New Granada, Venezuela, and Chili.....	500,000
“ “ Island of Cuba.....	1,200,000
“ “ India and China.....	1,000,000
Total.....	\$54,000,000

The importations from Great Britain into Mexico may be illustrated from a report made by order of parliament. For a period of 7 years from 1840 to 1846, both included, the sum total of the value of the imports was nearly \$82,246,705, making an average value of \$12,000,000 per annum. The principal articles of import were drugs, haberdashery, and wearing apparel, arms and ammunition, malt liquors, printed books, manufactures of brass and copper, furniture, carriages, coals, cordage, manufactures of cotton, earthenware of all kinds, glassware, hardware and cutlery, hats, iron and steel in bars, manufactured lead, prepared skins, harness and saddles, manufactures of flax, machinery and machines, and musical instruments. Of these articles, cotton fabrics rank highest, the estimated value of the importations for the 7 years amounting to more than \$57,000,000, while those of linen (which come next in order of value) were more than \$12,000,000, leaving only some \$12,000,000 or \$13,000,000 as the aggregate value of all the other imports from Great Britain into Mexico. Matamoras, Tampico, Tabasco, Minatitlan, Tehuantepec, and La Paz are engaged in trade with the United States; but the principal port is Vera Cruz, which was the place of destination of upward of ⅔ of the American imports of 1859. The following statement, made up from U. S. treasury reports, shows the total exports from Mexico to the United States and imports from the United States into Mexico from 1826 to 1859:

Exports.	Imports.	Exports.	Imports.
1826, \$2,916,000	\$4,281,000	1842, \$2,782,406	\$1,471,987
1827, 5,282,000	4,178,000	1844, 2,887,000	1,794,838
1828, 4,814,000	2,896,000	1845, 1,702,936	1,152,831
1829, 5,026,761	2,881,151	1846, 1,886,631	1,531,190
1830, 5,235,241	4,897,458	1847, 746,818	692,428
1831, 5,167,000	6,173,000	1848, 1,581,247	4,058,446
1832, 4,298,954	3,467,541	1849, 2,216,719	2,090,868
1833, 5,459,818	5,408,091	1850, 2,185,866	2,012,827
1834, 8,666,663	5,265,053	1851, 1,804,779	1,581,783
1835, 9,490,446	9,029,221	1852, 1,649,206	2,284,929
1836, 5,615,819	6,040,635	1853, 2,167,965	2,556,824
1837, 5,654,002	8,680,828	1854, 2,468,190	2,185,486
1838, 8,127,158	2,787,862	1855, 2,582,830	2,922,804
1839, 5,500,707	2,164,097	1856, 2,568,661	2,702,239
1840, 4,175,000	2,515,341	1857, 5,965,857	2,615,206
1841, 3,434,957	2,086,620	1858, 5,477,465	2,815,825
1842, 1,996,694	1,584,498	1859, 5,839,974	2,992,546
Total.....		\$184,585,800	\$112,729,578
Average per annum.....		8,928,950	3,815,585

The following is a statement of the trade of the United States with Mexico for the year ending June 30, 1859 :

Vessels.	Exports to Mexico.	Imports from Mexico.	Total.
American	\$2,056,284	\$3,119,445	\$5,175,729
Foreign.....	986,262	2,220,529	3,156,891
Total.....	\$2,992,546	\$5,339,974	\$8,332,620

Of the exports, \$2,307,170 was of domestic and \$685,376 of foreign produce. Of the imports, \$4,330,002 was free of duty. The importation of precious metals was as follows: gold coin, \$31,742; silver coin, \$3,924,062; gold bullion, \$5,662; silver bullion, \$184,424; total, \$4,095,890. The importation of gold and silver in 1858 amounted to \$4,868,964, and in 1857 to \$4,958,984. The commerce of the United States with the principal Mexican ports employed in the year ending Sept. 30, 1858, 116 vessels. Although it is impossible, in the absence of complete data, to give a correct statement of the interior commerce of the republic, or of the value of its domestic exchanges, it is, nevertheless, easy by calculation to arrive at an approximate result, taking as a basis the produce of its agriculture and industry, of the mines and cattle, as well as the conveyances of real estate, and finally the amount of foreign merchandise, computed according to its value in the native markets; all of which cannot be estimated at less than \$450,000,000 per annum; and, admitting that one half of the national products are not articles of mercantile speculation, on account of their passing from production to immediate consumption, and that the other half only pass through two hands ere disappearing from circulation, it appears that the interior commerce of the republic amounts, at the present date, annually, to more than \$400,000,000. As a proof that there is no exaggeration in the above estimate, it will suffice to say that, according to the mercantile statistics published by the chamber of commerce in Mexico, Puebla, Queretaro, Guanajuato, San Luis Potosi, and Guadalajara, from the years 1842 to 1846, inclusive, the value of domestic and foreign goods, including specie, legally introduced into these 6 departments alone, based upon the custom house valuation, which is generally less than the real value, amounted annu-

ally to more than \$140,000,000. The medium of exchanges by drafts, although not generally understood or adopted throughout the republic, being in operation only between the capital and such points as are open to foreign commerce and the principal cities, amounts, according to trustworthy data, to \$30,000,000 or \$40,000,000 per annum. The banking and discount business is also of some importance, in the city of Mexico alone amounting annually to between \$8,000,000 and \$10,000,000, and in the other parts of the republic to an equal sum.—The conveyance of all kinds of merchandise throughout the republic of Mexico is effected by pack mules, and wagons drawn by mules and oxen. With this system and the bad state of the roads generally, it will be easily understood that transportation is not only slow but costly, and one of the chief obstacles to the development of the great resources of the country. The average distance performed by mules and wagons is from 15 to 18 miles per day; but a company recently established runs a line of wagons between Vera Cruz and Queretaro, passing through the city of Mexico, which average during the dry season from 36 to 45 miles per day, thus performing the journey (390 miles) in 11 days. The cost of transporting merchandise varies much, according to the price of wages and fodder, always rising, however, during the rainy season. As a general thing, freights on the most frequented roads do not exceed two cents per arroba of 25 lbs. per Mexican league. Personal travelling is generally performed on horses or mules, which is not only the most economical, but in many cases the easiest way, owing to the narrow and precipitous roads. In some parts of the tropics, as for instance between Jalapa and Vera Cruz, litters supported by mules or men are used. For the general conveyance of passengers, beside private carriages, there is a line of diligences performing round trips from Mexico to Vera Cruz, to San Blas on the Pacific, and to various points of the interior, in the following order: to Puebla every day; to Orizaba and Vera Cruz, Pachuca and Toluca, 6 times a week; to San Blas, Morelia, Ouernavaca, Cuautla, Tulancingo, 3 times a week; and from Guanajuato to Leon, 3 times a week. Beside the above principal lines of diligences, there are others performing service between the following places 3 times a week: Puebla and Vera Cruz by Perote and Jalapa; Mexico, Ameca, and Ixmiquilpan; Guadalajara and Zaptlan; Lagos, Zatecas, and Aguas Calientes; Puebla, Matamoros, and Izucar; and Sisal and Merida. The fare by the diligences as a general rule varies from 20 to 40 cents per Mexican league. The diligences average from 9 to 12 miles an hour, according to the state of the roads. Arrangements are in contemplation for a good carriage road from the city of Mexico to Acapulco, which will enable passengers to travel at Vera Cruz to reach Acapulco on the Pacific coast with ease and despatch.—The national debt of Mexico is divided into interior and

exterior. The first arises out of sundry obligations contracted under the viceroyalty and after the independence; and the second out of loans contracted in London in the years 1823 and 1824. The capital of the foreign debt, or amount due under this head, according to the last convention, is £10,241,650, which, at \$5 per pound sterling, is equal to \$51,208,250; for 6 dividends due up to Dec. 31, 1855, \$4,608,741; total, \$55,816,991. The total amount of the interior debt, Dec. 31, 1850, after making the deduction prescribed by the law of Nov. 30 of the same year, was calculated at \$40,000,000, of which the *junta de credito publico* had recognized and liquidated the sum of \$16,829,775 up to Jan. 1, 1855; but as certain amounts paid previously, and the value of credits formed by after conventions, which figure separately, were taken after the above calculation, this debt did not amount at the beginning of 1857 to more than \$30,000,000, which has since been increased to \$61,950,033, making the total national debt \$117,767,024. Notwithstanding that a law was made, Nov. 24, 1856, designating the revenues of the supreme government and those of the states, it has not been put in practice, nor are the anterior laws on the subject enforced; the consequence of which is that many of the states, not having a systematized revenue, take such sums from the general fund at their disposal as they may require for their own wants. Sr. Lerdo de Tejada, in his *Cuadro sinoptico* (1856), says: "Notwithstanding that, under our present form of provisional government, we cannot well define the obligations which weigh upon the general and state governments, the latter have already assumed the responsibility of these internal expenses and administration, and the former has done likewise as relating to the whole nation, following the order observed under the federal system of 1852." The total annual expenditure of the general government, according to the statistics published by the minister of finance, Dec. 31, 1855, was \$14,228,325, as follows: government offices, public establishments, and improvements, \$5,394,181; army and navy, \$4,809,377; revenue officers and government necessities, \$765,827; public debt, interest, and sinking fund, \$3,584,690; municipality of Mexico, \$274,750.—There are no complete statistics in existence of the present state of education in Mexico. From partial returns it appears that in 1856 there were in the city of Mexico 123 primary schools, with 11,549 pupils; in the state of Vera Cruz (1854), 170 schools, 8,249 pupils; in Oaxaca (1852), 726 schools, 80,066 pupils; in Zacatecas and Aguascalientes (1850), 17,903 pupils; in Guanajuato (1850), 7,992 pupils; in Queretaro (1854), 4,402 pupils; in Puebla (1855), 17,664 pupils; in Tamaulipas (1854), 3,469 pupils; in Yucatan (1851), 4,234 pupils; in Tabasco (1856), 605 pupils; in Durango (1850), 8,031 pupils; in Sonora (1851), 756 pupils; in San Luis Potosi (1849), 3,900 pupils; and in the territory of Tlascala (1849), 3,170 pupils. From a comparison of these

numbers with the total population of the states mentioned, it appears that the proportion of pupils in the population is one in 37. The clergy maintain and control 10 seminaries, viz., one in each of the following cities: Mexico, Puebla, Morelia, Guadalajara, Monterey, Oaxaca, Merida, Durango, Chiapa, and Culiacan. These institutions contain collectively about 3,000 students. In the city of Mexico there is a university founded in 1551, which had at one period 200 students, but is now nearly deserted. There are beside 10 colleges or seminaries under the control of the government, viz.: the college of San Juan de Letran, with 171 students; of San Gregorio, with 140 students; of San Ildefonso, with 240 students; the school of medicine, with 206 students; the college of mines, with 228 students; the academy of fine arts, with 274 resident students and 7 maintained in Europe; the military college, with 97 students; the school of agriculture, with 45 students; and the school of commerce, with 87 students. The following states possess each a college maintained by the government: Mexico, Puebla, Oaxaca, Michoacan, Guanajuato, Durango, Zacatecas, Aguascalientes, San Luis Potosi, Chiapa, and Chihuahua. In the state of Vera Cruz there are four and in Queretaro two state colleges; and in Yucatan there are, beside the state college, a university at Merida and a naval school at Campeche. There are two public libraries in the city of Mexico: that of the cathedral, founded in 1788, which has 12,000 printed vols. and a great number of MSS.; and that of the university, founded in 1762, which has about 9,000 vols. In Puebla there is a college library of 30,000 vols.; and in Mexico, the library of the college of San Juan de Letran has 12,161 vols., and that of San Ildefonso 8,861 vols. The number of periodicals of all kinds in the republic was 44 in 1856, of which 11 were published in the city of Mexico.—The statement of the minister of justice and ecclesiastical affairs, presented in 1852, returns the number of the clergy as 4,615, of whom 1,043 were regulars. The number of nunneries was 58, containing a total of 1,484 nuns; beside which, there were 5 establishments belonging to the sisters of charity, with 37 sisters and 41 novices. The ecclesiastical hierarchy consists of one archbishop, at Mexico, and 12 bishops, at Puebla, Michoacan, Jalisco, Nuevo Leon, Oajaca, Durango, Yucatan, Chiapa, Sonora, Lower California, San Luis Potosi, and Vera Cruz. The revenues of the clergy may be divided into four great classes, viz.: 1, those of bishops and cathedral chapters; 2, those of private ecclesiastics and chaplains; 3, those of curates and vicars; and 4, those appertaining to various religious communities of both sexes. The first are principally composed of taxes known as tithes, or *diezmos y primicias*, the proceeds of which were formerly very great, consisting of one tenth of all produce gathered in the republic, and the first born of all domestic animals raised for profit. Latterly, however, this revenue has much de-

creased; as, by a law passed on Oct. 27, 1888, all farmers and laborers were released from obligation to pay it. Notwithstanding the law, there are many persons who, from conscientious motives, still continue to pay tithes. The clergy also receive the interest of large bequests left by devout persons for masses to be said for their souls. The bishoprics of Sonora, Lower California, New Leon, Chiapa, and Yucatan enjoy government pensions, amounting together to the sum of \$82,200. The college of "Our Lady of Guadalupe" has 25 lotteries, which are drawn annually, with a fund of \$18,000 each, some estates, and a capital of \$621,000 recognized by the government. The private ecclesiastics support themselves by revenues derived from chaplaincies, which are sums subscribed by religious persons for that purpose, amounting generally to about \$8,000, lent out at interest, and by the various sums received in charity and for saying masses. The revenue of curates is derived from parochial dues for baptisms, marriages, deaths, &c.; from masses said for particular persons; and lastly from the profits arising out of the sale of rosaries, medals, wax, &c. The revenue of convents is obtained by charity, masses, and burials in their own churches, beside the income from their valuable estates. The nunneries are supported by the produce of their estates, with the exception of one or two which do not possess any property, and are entirely supported by charity. There are several cathedrals and parishes deriving a revenue from estates and investments, which is appropriated to the wants and service of the clergy in general. It is difficult to arrive at the exact value and revenue of the property of the clergy, but an approximate estimate may be made, by taking as a basis the annual value of agricultural produce, the number of births, marriages, and deaths, &c. According to these tables, it can be safely computed that the total amount collected at this date by the clergy of Mexico, under the head of tithes, parochial dues, charities, masses, and sale of devotional articles, is from \$6,000,000 to \$8,000,000 annually. So far as regards the property of the clergy, some writers have estimated it as one half of the whole real estate in the country; others at one third. Setting these statements aside, the total value of their property—including sums subscribed for chaplaincies and gifts, estates, houses, churches, and other resources—may be computed at \$250,000,000 or \$300,000,000, notwithstanding the great losses which they are said to have suffered for some years past. In the city of Mexico alone, which contains 5,000 houses valued at \$80,000,000, the clergy own at least one half. The incomes of the above, added to the tithes and parochial dues, &c., warrant us in stating that the Mexican clergy collect throughout the republic annually a sum of \$20,000,000.—The earliest inhabitants of Mexico of whom we have any knowledge were the Toltecs, who, coming from the north, entered Anahuac in the 7th century

of the Christian era. They are said to have been skilful in agriculture and the mechanic arts; were nice workers of metals; and, in short, the true founders of the civilization of this part of the American continent. Their capital was Tula, N. of the Mexican valley. In the 11th century the Toltecs, reduced in numbers by famine, pestilence, and war, quitted Mexico and spread themselves over Central America, where they constructed great cities whose ruins still exist. To the Toltecs succeeded the Chichimecs, a rude tribe also from the north-west, who entered Anahuac about 1170. They were followed not long afterward by the Aztecs or Mexicans and Acolhuans or Tezcucans. The latter, a people of mild manners, readily imbibed some degree of civilization from the few Toltecs who had not followed the general emigration of their nation, and their capital, Tezcuco, on the eastern border of the lake of the same name, soon became a populous and comparatively a refined city. The Aztecs or Mexicans arrived in the valley about 1200, but they led a migratory and precarious life till 1825, when they founded the city of Mexico. About 100 years later the Tezcucans were subdued by a kindred nation, the Tepanecs. The Tezcucan prince Nezahualcoyotl organized an insurrection against the conquerors, and, with the aid of the Mexicans, succeeded not only in throwing off the yoke, but in subjecting the Tepanecs themselves, whose territory was given to the Mexicans in reward for their services. A league was then formed between Mexico, Tezcuco, and the neighboring little kingdom of Tlacopan, by which they agreed to support each other in war and to divide the spoils between them, one fifth to Tlacopan, and the remainder equally between the other states, according to most authorities. For a century of uninterrupted warfare this agreement remained in force, and was observed with fidelity. The allies soon conquered the whole of the valley, and in the middle of the 15th century, under Montezuma I., they carried their arms down the sides of the table-land to the borders of the gulf of Mexico. A succession of able princes still further extended their empire, and at the beginning of the 16th century, a few years after the discovery of America by Columbus, the Aztec dominion reached across the continent from the Atlantic to the Pacific, and the warlike emperor Ahuitzoll had successfully invaded and overrun Guatemala and Nicaragua.—The government was an elective monarchy, in which the sovereign was nearly absolute. Four of the principal nobles were the electors, who selected the new monarch from the brothers or nephews of his predecessor, thus keeping the line of succession always in the same family. The emperor was aided in the administration of affairs by councils composed of the principal nobles. The nobility seems to have consisted of the descendants of the earlier Aztec chieftains, who held large domains on condition of a sort of feudal service.

to the monarch. In each of the principal cities was a supreme judge, who had exclusive and final jurisdiction in both civil and criminal cases, and from whose sentence there was no appeal. Below this chief justice there was in each province a court of 8 judges appointed for life by the emperor, and beside these throughout the country a body of inferior magistrates elected by the people in their several districts. The people also elected other subordinate officers, to each of whom was assigned the superintendence of a certain number of families. The laws of the Mexicans were registered and spread before the people in hieroglyphical paintings. They related chiefly to the security of persons rather than of property. Great crimes were all made capital; the murder even of a slave was punished with death. Adulterers were stoned to death, and thieves punished either by slavery or death according to the magnitude of the property stolen. Prodigals and drunkards were punished with death; and it was a capital offence to remove the boundaries of another's land; to alter the established measures; and for a guardian not to be able to give a good account of his ward's property. Marriage was celebrated with formality, and a special tribunal determined all questions relating to it, and had the exclusive right of granting divorces. Slavery existed in a mild form, and was confined to prisoners of war, debtors, and poor persons who sold themselves for a living. The children of slaves were free, and no one could be born to slavery in Mexico. The code of the Aztecs, says Prescott, "evinces a profound respect for the great principles of morality, and as clear a perception of these principles as is to be found in the most cultivated nations." The revenues of the government were derived from crown lands, which appear to have been extensive; from a tax on agricultural products paid in kind; and from a tribute of manufactured articles furnished regularly by the cities and provinces. Spacious granaries and warehouses were established in the capital for the reception of these articles, and a receiver-general watched over the returns of the tax collectors. These taxes in the beginning of the 16th century had grown to be very oppressive, and their weight and the vigor with which they were exacted created a general dissatisfaction which contributed to the easy overthrow of the empire. Communication was maintained between the capital and the remotest parts of the country by means of couriers, for whose accommodation post houses at intervals of 6 miles were established on the great roads. These couriers bore despatches, in the form of hieroglyphical paintings, at the rate of 200 miles a day. The Mexicans, like the Spartans, made war the chief object of national concern. Their tutelary deity was the god of war, and to capture victims for his altars was the chief end of military expeditions. Their armies were divided into bodies of 8,000 men, and these were subdivided into companies of 300 or 400, each with its own captain. Their

discipline was such as to draw forth the praise of their Spanish conquerors. In battle they sought rather to capture than to kill their enemies, and they did not scalp their foes like the Indians of the north.—Of the religion of the Mexicans our information is very imperfect. They recognized the existence of a supreme creator and lord of the universe, whom they addressed as "the God by whom we live, omnipresent, that knoweth all thoughts and giveth all gifts, without whom man is as nothing; invisible, incorporeal, one God, of perfect perfection and purity, under whose wings we find repose and a sure defence." They, however, worshipped also a plurality of deities, who presided over the elements, the changes of the seasons, and the various occupations of man. Of these there were 18 principal deities, and 200 inferior. The chief of all these gods, the patron deity of the nation, was Huitzilopochtli, the god of war. His pyramidal temples were the largest and finest of the public edifices, and his altars erected on their summits reeked with the blood of human sacrifices in every city of the empire. Quetzalcoatl, the god of the air and of agriculture and the useful arts, was a beneficent deity, whose principal temple was the great pyramid at Cholula. The Mexicans imagined three separate states of existence in the future life. The wicked were to expiate their sins in everlasting darkness. The good, especially heroes who fell in battle or in sacrifice, passed at once into the presence of the sun, and after some years their spirits went to animate the clouds and beautiful singing birds in the gardens of paradise. A third class, who died of certain diseases, were to enjoy a negative existence of indolent contentment. In naming their children they used a ceremony strongly resembling the Christian rite of baptism, the lips and bosom of the infant being sprinkled with water, and the Lord implored to wash away the sin that was given to it before the foundation of the world, so that the child might be born anew. Among their moral precepts was one that said: "Keep peace with all; bear injuries with humility; God, who sees, will avenge you." Another declared that "he who looks too curiously on a woman commits adultery with his eyes." The priests were very numerous, as many as 5,000 being attached to the principal temple of the capital. Different orders were devoted to the service of different deities; and at the head of the whole ecclesiastical establishment were two high priests, elected by the sovereign and his council, and who ranked next to the emperor in dignity and power. The priests married, but while in attendance on the idols lived at the temples in a sort of conventual discipline. The priesthood was maintained by the produce of estates belonging to the temples, the surplus of which was given to the poor. The temples, called *teocallis*, "houses of God," were very numerous, there being hundreds in each of the principal cities. They were solid pyramidal

masses of earth cased with brick or stone, many of them more than 100 feet square and of a still greater height. The ascent was by flights of steps on the outside, and on the broad flat summit were sanctuaries containing the images of the deities and altars on which fires were kept always burning. Human sacrifices to their deities had been adopted as a part of their worship by the Mexicans early in the 14th century, and gradually became frightfully frequent, the annual number being stated by some authors at 50,000, and by nearly all at 20,000. The heart of the victim was torn out by the priests and cast at the feet of the idol, and his body afterward devoured at a solemn feast.—For purposes of record and communication the Mexicans used a species of picture writing which has been compared to the Egyptian hieroglyphics. (See MEXICAN PICTURE WRITING.) The traditions of the Mexicans were embodied in songs and hymns which were taught to the children in public schools. The only remains of their prose compositions which have reached us are prayers and discourses which show that they paid much attention to eloquence and rhetorical effect. They had also theatrical exhibitions of a pantomimic sort, in which the faces of the performers were covered with masks, and the figures of birds and animals were frequently represented. They had a simple system of arithmetical notation, in which the first 20 numbers were expressed by a corresponding number of dots. The number 20 was expressed by a flag, and larger sums were reckoned by twenties and expressed in writing by repeating the number of flags. The square of 20, 400, was denoted by a plume; and 8,000, the cube of 20, by a purse or sack. Half or $\frac{1}{2}$ of a plume or a purse represented that proportion of their respective sums, and so of other proportions. The year was divided into 18 months of 20 days each, and both months and days were expressed by peculiar hieroglyphics. Five complementary days were added to make up the 365; and for the fraction over of nearly 6 hours, required to make the full year, they added 18 days at the end of every 52 years. A month was divided into 4 weeks of 5 days each. The epoch from which the Mexicans computed their chronology corresponded with the year 1091 of the Christian era. They had no astronomical instruments except the dial, but their skill in the science of astronomy is shown by their knowledge of the true length of the year, of the cause of eclipses and of the periods of the solstices and equinoxes, and of the transit of the sun across the zenith of Mexico.—Agriculture was in a tolerably advanced state, the land being well managed and irrigated by canals. Granaries of admirable construction were provided to receive the harvests. The articles chiefly cultivated were the banana, the cacao, the fruit of which furnished chocolate, the vanilla, and maize, from whose stalks they manufactured sugar. From the maguey or Mexican aloe they obtained a paste by bruising the leaves, of which they

made paper, while its juice was fermented into *pulque*, an intoxicating beverage. Of the minerals, the Mexicans worked mines of silver, lead, tin, and copper, but were ignorant of the use of iron, for which they found a substitute in an alloy of tin and copper, with which they cut the hardest stones and gems. They cast also vessels of gold and silver, which they carried in a very delicate manner. Of *italli* or obsidian, a dark, transparent, and exceedingly hard mineral, they made knives and swords. For the ordinary purposes of domestic life they made utensils of earthenware and cups and vases of wood, gaudily painted. Among their dyes was the cochineal, with which they gave a brilliant color to cotton cloth. From a species of caterpillar they obtained a kind of silk. But their most peculiar and beautiful manufacture was feather work. The gorgeous plumage of tropical birds was pasted on fine cotton webs, with such taste and skill as to make garments of unequalled beauty and magnificence. There were no shops in the cities, their place being supplied by great markets which were held every fifth day under the inspection of officers appointed for the purpose. The different trades were arranged into something like guilds, and though the distinction of caste was unknown, it was usual for the son to follow the occupation of the father. Trade was held in high estimation, and merchants often attained to high political influence. Women were treated with tenderness and consideration. Polygamy was confined to the wealthy. Marriage was made with religious formalities, and its obligations were held to be strictly binding on both parties. The women partook equally with the men in social festivities and entertainments and passed their time at home in such feminine occupations as spinning and embroidery. The feasts of the Mexicans were often large and costly, and sometimes, especially at those of a religious character, cannibalism was practiced, a slave on such occasions being sacrificed and served up. "That such usages should have existed with the degree of refinement they showed in other things," says Prescott, "is almost inconceivable. It can only be explained as the result of religious superstition. . . . The Aztec character was perfectly original and unique. It was made up of incongruities apparently irreconcilable. It blended into one the many peculiarities of different nations, not only of the same phase of civilization, but as far removed from each other as the extremes of barbarism and refinement. It may find a fit parallel in their own wonderful climate, capable of producing on a few square leagues of surface the boundless variety of vegetable forms which belong to the frozen regions of the north, the temperate zone of Europe, and the burning skies of Arabia and Hindostan."—Such was the condition of the Mexicans when, in the summer of 1518, a Spanish squadron commanded by Juan de Grijalva discovered their country, which was then ruled by Montezuma II., who had been

elected emperor 16 years before, and had distinguished himself by energy, enterprise, and extensive conquests in Central America. In November of the same year Hernan Cortes sailed from Cuba on the enterprise which resulted in the conquest of the empire by the Spaniards. (See CORTES.) From 1535 to 1808 Mexico was governed by Spanish viceroys, who succeeded each other to the number of 56, of whom only one, Don Juan de Acuña, marquis de Casa Fuerte, was born in America. He was a native of Peru, and governed Mexico from 1722 to 1734, with a reputation for ability and integrity. The most distinguished of the viceroys was the count de Revilla-Gigedo, whose administration lasted from Oct. 17, 1789, to July 11, 1794. Under his direction good roads leading from the capital in various directions were laid out, the principal cities were paved and lighted and a good police formed in them, and many other practical improvements of importance were carried into effect. By the Spanish colonial system the viceroy of Mexico possessed all the powers of royalty, checked only by the dread of the investigation into his conduct which might be made after his return to Spain, and by the authority of the *audiencia* or court of appeal of Mexico, a highly influential body, which corresponded directly with the king and the council of the Indies, and whose sanction was necessary to give the viceregal decrees the force of law. The viceroy, however, was president of the *audiencia*, and its members, though independent in theory, were in practice generally subservient to his wishes. All official posts in Mexico were filled by Spaniards, and the colonial offices were regularly sold in Madrid to the highest bidder. To keep the native Mexicans in ignorance, almost every kind of useful learning was prohibited to them. Their industry and the material development of the country were hampered by severe restrictions. They were not allowed to cultivate flax, hemp, saffron, the olive, the vine, or the mulberry, and they were forbidden to manufacture any thing which could be supplied by the mother country. For a long time foreign trade was prohibited on pain of death. In addition to these injurious and degrading restrictions for the selfish interest of Spain, the Mexicans were heavily taxed and subjected to all the evils of an arbitrary government and a corrupt and partial administration of justice. The news of the invasion of Spain by the French in 1808, and the proclamation of Joseph Bonaparte as king, was received with great indignation in Mexico, and with manifestations of the most ardent loyalty to Ferdinand VII. The viceroy at this period was Don José Iturrigaray, who endeavored to form a provisional government partly composed of natives; but the Spaniards in the capital, averse to allowing the Mexicans any share in the administration of public affairs, armed themselves, and, seizing the viceroy in his palace on the night of Sept. 15, 1808, sent him a prisoner to Spain, and assumed

themselves the reins of government. This proceeding, and the conduct of the new viceroy Venegas, who brought from Spain rewards and distinctions for the leaders of the revolt against his predecessor, and who persecuted those who had supported the plan of a provisional government, alienated and incensed the natives. A conspiracy was formed, and in Sept. 1810, a revolt broke out in the province of Guanajuato, headed by a priest, Don Miguel Hidalgo, who possessed considerable talent and had much influence among the Indian part of the population. This insurrection, which aimed at driving the Spaniards from Mexico, soon assumed formidable proportions, Hidalgo having at one time 100,000 men under arms. After his defeat and death in 1811, the contest was continued by Morelos, also a priest, who called a national congress, which met at Chilpanzingo, Sept. 18, 1813, and on Oct. 13 declared Mexico independent. On Oct. 22, 1814, it promulgated at Apatzingan a constitution which is known by the name of that place. After several defeats Morelos was captured, carried to the city of Mexico, and executed as a rebel, Dec. 22, 1815. For several years subsequently the contest became a mere partisan warfare on the part of the patriots, of whom the principal chiefs were Victoria, Guerrero, Bravo, Rayon, and Teran. These were gradually driven from the field, and were killed, imprisoned, or obliged to hide like wild beasts in the mountains, till at the beginning of 1820 the authority of Spain appeared to be fully re-established in Mexico. But in the course of that year the news of the revolution in Spain, and of the proclamation of the constitution which Ferdinand VII. had been compelled to adopt, renewed the agitation among the Mexicans in favor of a liberal government. Don Augustin Iturbide, a native Mexican and an officer of the army, who during the recent civil war had distinguished himself on the royalist side, now threw off his allegiance and began the second revolution by proclaiming Mexico independent, Feb. 24, 1821, and proposing a constitution known as the "plan of Iguala," from its promulgation at the town of that name. The principal points of this "plan" were the recognition of Roman Catholicism as the national creed, the abolition of all distinctions founded on caste or color, and the establishment of a constitutional monarchy, the crown to be offered to Ferdinand VII., and if refused by him to the infantes Don Carlos and Don Francisco de Paula. The revolt of Iturbide was eminently successful. In the course of a few months the whole country recognized his authority except the capital, and by a treaty signed at Cordova, Aug. 24, 1821, with the viceroy, Don Juan O'Donoju, he obtained possession of the capital on Sept. 27, and instituted a regency of which he was the head. Eight months later, with the support of the army and the mob of the city of Mexico, Iturbide was proclaimed emperor, on the night of May 18, 1822, under the title of Augustin I. His reign lasted but 10

months, a successful insurrection commenced by Santa Anna at Vera Cruz compelling him to abdicate, March 20, 1823. A provisional government, at the head of which were Generals Victoria, Bravo, and Negrete, was now appointed; and a congress having assembled, a federal constitution similar to that of the United States was promulgated, Oct. 4, 1824, by which Mexico was formed into a republic with 19 states and 4 territories. Gen. Vittoria was elected president and Gen. Bravo vice-president, for a term of 4 years. In 1828 Gen. Gomez Pedraza was elected president by the votes of the party called *Escosses* or Scots, over Gen. Guerrero, the candidate of the *Yorkinos* or Yorkists. These names were taken from rival masonic associations, one of which derived its origin from the grand lodge of Scotland, and the other from that of York, England. The electoral majority for Pedraza was only two, and the partisans of Guerrero declared that the election had been carried against them by fraud and corruption, and rose in insurrection under the lead of Santa Anna. A sanguinary revolution ensued, during which the Spaniards, of whom a considerable number still resided in Mexico, and who generally sympathized with the party of the *Escosses*, were plundered by the mob and driven from the country. Pedraza resigned his claim to the presidential office in Jan. 1829, and Guerrero was declared duly elected, and entered upon the office on April 1. In the following summer the country was invaded by a Spanish army under Gen. Barradas, which landed at Tampico July 27, but was compelled to surrender to Gen. Santa Anna on Sept. 10. Guerrero on the approach of the invaders had been invested with dictatorial powers, and his persistence in exercising them after the defeat of the Spaniards furnished a pretext to Bustamante and Santa Anna for exciting a revolt and marching upon the capital with the troops from Vera Cruz. Guerrero was compelled to resign, and the army elected Bustamante to the vacant office. A few months later Guerrero attempted by force to regain the presidency, but was captured and executed, Feb. 14, 1831. Revolutions now followed in rapid succession, until in 1838 Santa Anna became president, and Bustamante and his principal adherents were sent into exile. Congress now passed laws abrogating the authority of the pope over the Mexican church, suppressing the convents, and abolishing the compulsory payment of tithes. It also proposed to appropriate the property of the church to the payment of the national debt, but this measure led to insurrections and to further complications, which ended in 1835 in the abrogation of the constitution of 1824 and the conversion of the confederation of states into a consolidated republic, of which Santa Anna was nominally constitutional president, and practically dictator. This revolution was acquiesced in by all parts of the country except Texas, where several thousand Americans had settled as colonists. The refu-

sal of the Texans to submit to the centralized government, which they pronounced a usurpation and its chief a dictator, induced Santa Anna to march against them in the beginning of 1836 with an army, which was defeated and annihilated at San Jacinto, April 21, the Mexican president himself being taken prisoner. In the previous month a convention of delegates assembled at the town of Washington had declared Texas an independent republic. The captivity of Santa Anna threw Mexico again into confusion. Bustamante became president from April 19, 1837, to March 18, 1839, when he was succeeded by Santa Anna, who, after a visit to President Jackson at Washington, had been sent back to Mexico in a U.S. ship of war in 1836. He held the office as provisional president till July 10, 1839, when Nicholas Bravo became president for a week. A long period of confusion followed, during which the constitution was suspended and the government became a dictatorship, at the head of which were successively Santa Anna, Bravo, and Canalizo, from Oct. 10, 1841, to June 4, 1844. Constitutional government was resumed in 1844 with Santa Anna as president, under a constitution promulgated June 12, 1848. He was deposed and banished by a revolution, and was succeeded, Sept. 20, 1844, by Canalizo, who was deposed by a revolution, Dec. 6 of the same year. His successor, Herrera, was also driven from office by a revolution, Dec. 30, 1845, when he was succeeded by Gen. Paredes, under whose administration war commenced with the United States by conflicts on the Rio Grande between the Mexican army under Gen. Ampudia and the army of Gen. Taylor. During the war various revolutions occurred, in one of which Santa Anna, whose return from exile had been connived at by the American government, regained the supreme power, which he made use of to carry on the struggle against the Americans with vigor. He was defeated by Gen. Taylor at Buena Vista, and by Gen. Scott at Cerro Gordo and in several battles in the vicinity of Mexico city; and the treaty of Guadalupe Hidalgo, by which, in Feb. 1848, the war was closed and New Mexico and California ceded to the United States, was followed by his forced retirement to Jamaica, and the elevation of Herrera to the presidency under the federal constitution of 1824, which had been reestablished in 1846. Herrera was succeeded, Jan. 15, 1851, by Gen. Arista, who, on Jan. 1, 1853, was compelled by a revolution to resign. By a decree issued March 17, 1853, Santa Anna was recalled, and for the 5th time was placed at the head of the government, April 20, with the title of president, but with limited powers. He endeavored to make himself rule perpetual, and was suspected of a design to convert the republic into a monarchy. Juan Alvarez, governor of the state of Guerrero, "the panther of the Pacific," began an insurrection against the dictator at Acapulco, Jan. 22, 1854, which received the cooperation of Haro y Tamariz, Comonfort, Degollado, and

other eminent men, and resulted in the flight of Santa Anna from the country in Aug. 1855, and the elevation of Gen. Carrera to the presidency, which he held for 27 days, being compelled to retire Sept. 12. After 3 weeks of anarchy, Alvarez was made president by a junta, and held the office from Oct. 4 to Dec. 11, when he retired and delegated his authority to Comonfort. The latter soon took active measures against the influence of the clergy, who were strongly opposed to his administration. On March 31, 1856, he confiscated by a decree the property of the church, and on June 28 issued another forbidding the clergy to hold real estate. These proceedings led to revolts in the latter part of the year, but they were promptly suppressed. Congress, on March 11, 1857, promulgated a new constitution, which greatly restricted the power of the president. The army was opposed to this constitution, and in Jan. 1858, a revolution broke out which soon terminated in the resignation of Comonfort and the elevation of Gen. Zuloaga to the presidency, by the conservative party. According to the provisions of the constitution, by the resignation of President Comonfort his office devolved on Benito Juarez, chief justice of the supreme court, who was supported by the liberal party and by the greater part of the country, while the conservatives held Mexico and a few other cities. Juarez assembled an army to maintain his right, but was defeated by Zuloaga and retired to Panama, whence he proceeded to Vera Cruz and established himself there, May 4, as constitutional president. Subsequently Zuloaga was deposed by Gen. Robles, who made a futile effort to unite the liberals and conservatives. Gen. Miramon then became chief of the conservatives, and the civil war between him and the leaders of the liberals still continues (Sept. 1860).

MEXICO, a state of the Mexican republic, between lat. $18^{\circ} 30'$ and $21^{\circ} 57' N.$, and long. 95° and $101^{\circ} W.$, bounded N. by the state of Queretaro, N. E. by Vera Cruz, E. by Puebla, S. W. by Guerrero, and W. by Michoacan; area, 19,535 sq. m.; pop. 1,002,044. It lies entirely on the high table land, and has a mountainous surface, including several volcanoes and the peak of Toluca, which reaches the region of perpetual snow, 15,000 feet above the sea. The finest portion of the state is the great valley of Mexico, which is oval in form and about 250 miles in circumference. The soil of the state is remarkable for its fertility, and produces in abundance every variety of plants. To the S. E. of the great valley is a rich silver mining district, and there are also valuable mines of iron, lead, and carbonate of soda. Beside Mexico city, the federal capital, around which there is a small district under the exclusive jurisdiction of congress, the chief towns are Lerma, Cuicaco, San Augustin, Cuernavaca, and Toluca, the state capital, which is about 27 m. S. W. of the federal metropolis.

MEXICO, a city and the capital of the republic of Mexico, situated about $2\frac{1}{2}$ m. W. of Lake Tez-

cuco, in the valley of Mexico, in lat. $19^{\circ} 25' 45'' N.$, long. $103^{\circ} 45' 30'' W.$, 7,400 feet above the level of the sea; pop. estimated at 200,000. The present city of Mexico occupies a part only of the site of the ancient city destroyed by Cortes, and is consequently much smaller than the capital of the Montezumas. It is, however, a large and splendid city, inferior to none in the world in the magnificence of its appearance and site. Humboldt, who visited Mexico in 1803, calls it one of the finest cities ever built by Europeans. He states that he had seen successively within a short space of time Lima, Mexico, Philadelphia, Paris, Rome, Naples, and the largest cities of Germany; and yet, on comparing the impressions made by them, he says that Mexico had left on his mind a recollection of distinguishing grandeur, which he attributes in part to the majestic character of its situation and the surrounding scenery. A recent French traveller, J. J. Ampère, says: "Mexico is a grand city in the Spanish style, with an air more imposing, more majestic, more metropolitan than any city of Spain except Madrid. Crowned by numerous domes and steeples, and surrounded by a vast plain bounded by mountains, Mexico reminds one somewhat of Rome. Its long streets, broad, straight, and regular, give to it an appearance like Berlin. It has also some resemblance to Naples and Turin, yet with a character of its own. It makes one think of various cities of Europe, while it differs from each of them. It recalls all and repeats none." The city forms a square, and the streets intersect each other at right angles. The squares thus formed are of nearly equal dimensions throughout the city, and have each a distinct appellation, no street having the same name in its whole extent. The houses are generally 3 stories high, and massively built of stone, without intervening spaces, each block forming one compact structure. In the interior of each house is a *patio* or court, which communicates with the street by a door large enough to admit a coach. From the *patio* stairs lead to the upper stories and to the roof, which is flat and enclosed by an ornamental iron balustrade. The Plaza Mayor, or great square, is in the centre of the city, and covers an area of 12 acres paved with marble. On the N. side of this square stands the cathedral, 500 feet in length and 420 in breadth. It was 94 years in building, from 1573 to 1667, and occupies the site of the principal temple of the ancient city. Its appearance is imposing, though the architecture is an irregular mixture of the Gothic and the Italian style. The front is decorated with carving, and there are two towers of considerable height ornamented with statues. The interior is rich and gorgeous, and the numerous crucifixes, candlesticks, reliquaries, &c., of gold and silver adorned with jewels, are said to be of immense value. Within the enclosure of the cathedral is a remarkable stone called the "stone of sacrifice," which is of porphyry about 9 feet in diameter, and is covered with sculptures; it is supposed to have

been used by the ancient Mexicans for the sacrifice of human victims. In the wall of the cathedral is a stone called the Aztec calendar, also of porphyry, and weighing about 24 tons; it is circular in form, and is covered with hieroglyphics representing the months of the year. On the E. side of the Plaza Mayor is the national palace, formerly the palace of the Spanish viceroys. This is a fine edifice, nearly square, with a front of several hundred feet, and in the interior 4 large square courts. It is the official residence of the president, and contains also the halls of congress, the mint, two prisons, and many public offices, together with several shops. At the S. E. corner of the great square is the city hall, which contains also the merchants' exchange. The rest of the square is surrounded by private dwellings. The university, the school of sciences, and an extensive market occupy considerable buildings near the square. There are beside the cathedral about 60 churches and convents, most of them large and richly ornamented. The Acordada is a vast and strong prison, which will contain 1,200 convicts. The Plaza de Toros is an arena for the exhibition of bull fights, which will accommodate nearly 8,000 spectators. The city contains several *portales*, or covered colonnades, lined with shops, which form favorite promenades, especially in the evening. There is at the W. end a park of about 12 acres, called the Alameda or public walk, which has many fine trees. On the same side of the city is a *paseo* or promenade, $1\frac{1}{2}$ m. in length, planted with double rows of trees. Two aqueducts supply Mexico with water, one of which, upward of 6 m. in length, extends from Santa Fé to the Alameda, and is supported for one third of its course on arches. The southern suburbs are supplied by the aqueduct of Chapultepec, which is upward of 2 m. long. The most important manufactures of the city are those of tobacco, gold and silver lace, plate, jewelry, soap, and coaches. The commerce of Mexico, however, is small, and it is supported chiefly by the presence of the government. The markets are well supplied with fruits and vegetables, comprising the best productions of the temperate and torrid zones, from gardens on islands in the adjacent lakes, and with beef, mutton, pork, poultry, and game.—The population of Mexico is of a singularly varied character, about $\frac{1}{2}$ consisting of whites of Spanish descent, $\frac{1}{4}$ of Indians, and $\frac{1}{4}$ of mestizoes, mulattoes, zamboes, negroes, and foreigners of nearly all nations. Though many families possess immense wealth, the mass of the people are poor; and the lowest class of all, the *leperos*, are remarkably idle, squalid, and vicious, resembling in character as well as in number the *lazzaroni* of Naples.—The chief historical interest of Mexico is based upon its identity of site with the ancient city, the capital of the Montezumas. The Aztecs or ancient Mexicans, after their migration from the north, wandered for a long time in the Mexican valley, till in 1325 they halted on the S. W. borders of the lake of Tez-

cuco, and there beheld one morning an eagle of extraordinary size perched on the stem of a cactus growing out of a rock, with a serpent in his talons, and his wings spread to the rising sun. An oracle announced the omen as auspicious, and as indicating the site of their future metropolis; and they began its foundations by sinking piles into the marshes on which they erected huts of reeds and rushes. They called the place Tenochtitlan, "cactus on a stone," in allusion to the omen. Its name of Mexico was subsequently derived from that of their god Mexitli. By the middle of the 15th century the city had become large and prosperous, and reeds and rushes were supplanted by stone and lime; and when on the evening of Nov. 7, 1519, its long lines of glittering edifices first met the eyes of the followers of Cortes, it looked, says Prescott, like a thing of fairy creation rather than the work of mortal hands. On their entry into Mexico next day the Spaniards found fresh cause for admiration in the grandeur of the city and the superior style of its architecture. The great avenue through which they marched was very wide, and extended straight through the heart of the city. It was lined with the houses of the nobles, built of a red porous stone drawn from quarries in the neighborhood. The flat roofs were protected by stone parapets, so that every house was a fortress. Occasionally a great square or market place intervened, surrounded by porticoes of stone and stucco; occasionally a pyramidal temple of colossal size, crowned with tapering sanctuaries and blazing altars. But what most impressed the Spaniards was the throng of people who swarmed through the streets, filling every doorway and window and clustering on the roofs. Nothing certain, however, is known of the amount of its population. "No contemporary writer," says Prescott, "estimates it at less than 60,000 houses, which, by the ordinary rules of reckoning, would give 800,000 souls. If a dwelling often contained, as is asserted, several families, it would swell the amount considerably higher. The concurrent testimony of the conquerors; the extent of the city, which was said to be nearly 8 leagues in circumference; the immense size of its great market place; the long lines of edifices, vestiges of whose ruins may still be found in the suburbs, miles from the modern city—all attest the numerous population far beyond that of the present capital. Though a few of the streets were wide and of great length, most of them were narrow and lined with mean houses. The great streets were intersected by numerous canals crossed by frequent bridges. The palace of Montezuma was near the centre of the city, and was a pile of low irregular stone buildings, so vast that one of the conquerors says, although he had visited it more than once for the express purpose, he had been too much fatigued each time by wandering through the apartments ever to see the whole of it. Another palace, assigned to Cortes on his entrance into the city, was so large as to accommodate his whole army. But

the most remarkable edifice of the city was the great *teocalli* or temple, which had been completed and dedicated in 1486. It stood in the midst of a vast area encompassed by a stone wall about 8 feet high, ornamented on the outer side by figures of serpents in bass-relief. This wall was pierced on its 4 sides by gateways opening on the 4 principal streets. Over each of the gates was an arsenal, and there were barracks near the temple garrisoned by 10,000 soldiers. The temple itself was a solid pyramidal structure of earth and pebbles, coated externally with hewn stones. It was square, its sides facing the cardinal points, and was divided into 5 stories, each of which receded so as to be smaller than that below it. The ascent was by a flight of steps on the outside, so contrived that to reach the top it was necessary to pass 4 times round the whole edifice. There were 114 steps, and the base of the temple is supposed to have been 300 feet square. The summit was a large area paved with broad flat stones. On it were two towers or sanctuaries, and before each an altar on which burned a fire that was never suffered to go out. The view from this summit, as seen by the Spaniards on their first visit, is thus described by Prescott: "Below them, the city lay spread out like a map, with its streets and canals intersecting each other at right angles, its terraced roofs blooming like so many parterres of flowers. Every place seemed alive with business and bustle; canoes were glancing up and down the canals; the streets were crowded with people in their gay, picturesque costume; while from the market place a confused hum of many sounds and voices rose upon the ear. They could distinctly trace the symmetrical plan of the city, with its principal avenues issuing as it were from the 4 gates of the temple, and connecting themselves with the causeways, which formed the grand entrances to the capital. They could discern the insular position of the metropolis, bathed on all sides by the salt floods of the Tezcuco, and in the distance the clear fresh waters of the Chalco; far beyond stretched a wide prospect of fields and waving woods, with the burnished walls of many a lofty temple rising high above the trees, and crowning the distant hill tops. The view reached in an unbroken line to the very base of the circular range of mountains, whose frosty peaks glittered as if touched with fire in the morning ray; while long dark wreaths of vapor, rolling up from the hoary head of Popocatepetl, told that the destroying element was indeed at work in the bosom of the beautiful valley." The police of the city was efficient and vigilant; and 1,000 men were daily employed in watering and sweeping the streets. As the lake that surrounded the city was extremely brackish, pure water for the supply of the people was brought by an aqueduct from the neighboring hill of Chapultepec, where Montezuma had a summer palace surrounded by vast and magnificent gardens. In the final siege by the Spaniards, Cortes, despairing of otherwise sub-

duing a place where every house was a fortress and every street was cut up by canals, reluctantly determined to destroy the city, which he calls "the most beautiful thing in the world." With the aid of his multitudinous Indian allies, whose hatred of the Aztecs led them to work with zeal, in a few weeks seven-eighths of the city was levelled to the ground, and the canals filled with the rubbish. Soon after the termination of the siege Cortes began to rebuild the city on its present plan, assembling for the work a host of Indians, estimated by one Mexican writer at the incredible number of 400,000. During its occupation by the Spaniards, from 1521 to 1821, the most remarkable events in the local history of Mexico were 5 great inundations in 1558, 1580, 1604, 1607, and 1629, caused by the overflowing of the neighboring lakes. To prevent the recurrence of these inundations a great drain was dug through the hill of Nochistongo, by which the waters of the river Guantitlan were led out of the valley instead of falling into the lake of Tezcuco. This work, which was upward of 100 years in process of construction, is about 12 miles long, from 100 to 180 feet deep, and between 200 and 300 feet wide. It was completed in 1789. Since the republic was established, the city of Mexico has been the scene of several revolutions and insurrections, and a number of important battles have been fought in the vicinity. The most noted of these were the battles of Ohurubusco and Contreras, Aug. 20, 1847, and of Chapultepec, Sept. 13, fought between the American army commanded by Gen. Scott, and the Mexican army commanded by Gen. Santa Anna. The latter battle was followed by the occupation of the city, on Sept. 14, by the Americans, who held it till it was evacuated in compliance with the treaty of Guadalupe Hidalgo, which was ratified in May, 1848.

MEXICO, GULF OF, a basin of the Atlantic ocean enclosed by the United States, the West Indies, and Mexico, and measuring about 1,000 m. from E. to W. and 800 from N. to S.; estimated area, 800,000 sq. m. The states of Florida, Alabama, Mississippi, Louisiana, and Texas border upon it on the N., and the Mexican states of Tamaulipas, Vera Cruz, Tehuantepec, Tabasco, and Yucatan on the W. and S. Its entrance, between Cape Sable at the extremity of the peninsula of Florida, and Cape Oatoche at the extremity of the peninsula of Yucatan, is about 500 m. in width; but midway across this mouth lies the island of Cuba, leaving a passage on either hand, viz.: the strait of Florida on the N. E., 120 m. wide, communicating with the Atlantic, and the channel of Yucatan on the S. W., communicating with the Caribbean sea, 105 m. wide. West of Yucatan extends the broad bay of Campeachy; on the coast of Texas are the bays of Corpus Christi, Aransas, Matagorda, and Galveston; in Louisiana are those of Vermilion, Atchafalaya, Barataria, Black, and Lake Borgne; in Alabama Mobile bay, in Mississippi Mississippi sound, and in Florida Pensacola harbor, Appalachicola, Appalachee, Tampa, and

Charlotte bays, and the bay of Ponce de Leon. Beside these, the coasts, being mostly low and marshy or sandy, are lined with numerous lagoons. There are few islands except some small ones belonging to Yucatan, a number near the delta of the Mississippi, and the Florida keys. The most important rivers of the gulf are the Suwannee and Appalachicola in Florida; the Mobile in Alabama; the Pascagoula and Pearl in Mississippi; the Mississippi in Louisiana; the Sabine, Trinity, Brazos, Colorado, Nueces, and Rio Grande in Texas; and the Tampico in Mexico. These streams are nearly all obstructed by bars at their mouths, and there are very few good harbors; Havana, Mobile, Galveston, and Vera Cruz are the most important.—The depth of the gulf is believed not to exceed three quarters of a mile. The officers of the U. S. ship Albany ran a line of deep-sea soundings across the gulf from W. to E., and reported a maximum depth of 6,000 feet; but subsequent experiments have led to the belief that it is really not so great. The reefs and shoals on the N. shore of Cuba and about the Florida keys render the passage into the Atlantic exceedingly intricate, but elsewhere there are few banks; the only large one lies about lat. 27° N., long. 86° W., 200 m. S. from Cape San Blas. Beside the N. E. and S. E. monsoons which prevail in the gulf, it is visited by violent northern gales, called *nortes*, which begin in September or October, and reach their greatest strength in March. They commonly terminate in this month, but sometimes last until April. The most remarkable phenomenon connected with the gulf of Mexico is the Gulf stream (see ATLANTIC OCEAN, vol. ii. p. 298), which enters it by the channel of Yucatan, passes around it, and flows out by the strait of Florida. The temperature of the gulf, owing partly to this great influx of water from the torrid zone and partly to the proximity of the burning *tierras calientes* of Mexico, is about 8° or 9° higher than that of the Atlantic ocean in the same latitude. In its centre are found great quantities of *fucus natans* or gulf weed, floating in parallel lines from S. S. E. to N. N. W.—By some geographers the term gulf of Mexico is applied to all that part of the Atlantic lying W. of the E. extremity of the West India islands, extending therefore from the Bahamas to the Orinoco, and including, beside the gulf proper, the Caribbean sea.

MEYER. I. FELIX, a Swiss painter, born in Winterthur, canton of Zürich, in 1653, died in 1718. He studied painting under Ermels in Nuremberg, and subsequently passed some time in Italy, but returned to Switzerland, and gained a considerable reputation by his views of Swiss scenery. He was employed throughout Germany by princes of the empire and others in ornamenting their apartments. II. JOHANN HEINRICH, a German artist and writer on art, born in Stafa, on the lake of Zürich, March 16, 1759, died in Weimar, Oct. 14, 1832. He was for some time the pupil of J. C. Füssli, the brother of Henry Fuseli, and in 1786 visited

Rome, where he commenced an intimacy with Goethe, which became of so close a character that Meyer was familiarly known in Germany as Goethe-Meyer. In 1797 he established himself in Weimar, and 10 years later was appointed director of the academy of painting in that city, a position which he retained until the close of his life. As a painter his productions were few and of little importance; but he possessed a profound knowledge of the principles and history of antique art, and during his whole residence in Weimar was the consulting oracle of Goethe on the subject. Many portions of Goethe's *Kunst und Alterthum*, *Winckelmann und sein Jahrhundert*, *Farbenlehre*, and other publications on art, are supposed to reflect the opinions of Meyer. Meyer was the principal editor of Winckelmann's works, which were published in Dresden in 1808-'20 in 8 vols., and furnished most of the elaborate notes illustrating them. The latter were afterward rearranged by him in the form of a consecutive history of Greek art, under the title of *Geschichte der bildenden Künste bei den Griechen* (2 vols. 8vo., Dresden, 1824), to which a posthumous volume illustrating the progress of Greek art among the Romans was subsequently added (8vo., Dresden, 1836). III. HERMANN, a German naturalist, born at Frankfort-on-the-Main, Sept. 8, 1801. He was brought up in a banking house, in 1822 studied jurisprudence and chemistry at Heidelberg, and subsequently became a member of the municipal government of his native city and an administrator of the exchequer of the Germanic confederation. Apart from his public duties he has been an enthusiastic student of the natural sciences, and has made several important additions to the literature of geology and palæontology. Since 1841 he has been engaged upon an elaborate work entitled *Zur Fauna der Vorwelt*, which is not yet finished. IV. LUDWIG, a German physiologist, born in Bielefeld, Westphalia, in 1825. He was educated at a Jesuit college in Paderborn, and in 1848 went to the university of Bonn to study medicine. Joining with ardor in the revolutionary movement instigated by Kinkel and others, he was arrested and in 1849 put on trial for his life; but he argued his own case, and was promptly acquitted by the jury. He then repaired to Würzburg to study pathological anatomy, and subsequently pursued the same subject at Berlin under Müller, Reinhard, and others. Receiving in 1853 the appointment of assistant physician in the insane department of the Charité hospital in Berlin, he left his previously chosen field of pathological anatomy and devoted himself exclusively to the study of mental diseases. In 1855-'7 he had the charge of the new insane asylum at Schwetitz in East Prussia, but in 1858 he resumed his post at the Charité, and became also a private instructor at the university of Berlin. In the latter year he published a small work on insanity which led to his appointment as director of the insane department of the hospital at Hamburg, a post

tion he still occupies. He traces all mental disease to some disarrangement of the physical system, and divides cases of insanity into two principal classes, one in which the disease is "idiopathic," or emanating from the brain, and the other in which it is "sympathetic" or "reflected,"—that is, the cause is to be sought for in some other part of the body.

MEYERBEER, GIACOMO, a dramatic musical composer, born in Berlin, Sept. 5, 1794. His original name was Jakob Meyer Beer, which he changed for its present form. His parents belonged to a Jewish family distinguished alike for wealth and love of letters and art, and especially of music. His father held a high position in the financial and commercial world of Berlin, and his house became a favorite resort of the artistic, literary, and social celebrities of the Prussian metropolis. These associations and the highly intellectual atmosphere of their domestic life had a happy effect upon the æsthetic development of his children. His younger sons, Michael Beer (died 1838) and Wilhelm Beer (died 1850), both attained to eminence, the former as a dramatic author, the latter as an astronomer. Giacomo, the eldest son, displayed from his earliest childhood remarkable musical capacities, which were assiduously encouraged by those around him. It is said that in his 5th year he used to play little tunes spontaneously on the piano. His first teacher on that instrument was Franz Lauska, a Bohemian by birth, and an artist of some local reputation. In the theories of music he was instructed by Karl Friedrich Zelter, a friend of Goethe, and afterward teacher of Mendelssohn-Bartholdy. His performance on the piano soon elicited general admiration. He preferred, however, to devote himself to the study of dramatic composition. Bernhard Anselm Weber was his first instructor in that branch of the art; but in order to perfect himself in the composition of the fugue, the customary basis of a thorough training in counterpoint and of the art of conducting several themes or melodies in harmonic combination, he required the assistance of a superior master. This he found in Georg Joseph Vogler, who was at that time one of the most eminent scientific musicians and the principal organist of Germany, and who had opened in Darmstadt a school to which only young men of remarkable talent were admitted. Meyerbeer, upon the cordial invitation of Vogler, joined this school in Feb. 1810, and his more scientific musical studies date from that period. While there, he became acquainted with Karl Maria von Weber, who, after having already composed several operas, had resumed his studies at Darmstadt. The two young men, joined by Günsbacher and other pupils who have since attained to eminence, assembled daily in the rooms of Vogler, where a theme for musical composition was given to each of them, including the professor, which was elaborated during the day and executed in the evening. Meyerbeer and Weber lived together for nearly two years in

the same room, and their intimate relation lasted until the death of the latter composer (1826), who left the last two acts of his opera, "The three Pintos," to be completed by his friend. While in Darmstadt Meyerbeer composed an oratorio, *Gott und die Natur*, which was received with great favor by the grand ducal family, and caused him to be appointed composer to the court. After a course of study for about two years, he set out on the tour of Germany, in company with Vogler, under whose auspices he produced his opera "Jephthah" at Munich in 1812. This, on account of its scientific precision, gave so much satisfaction to his good teacher, that he pronounced him to have reached the climax of musical science, and handed him his official diploma as "maestro." Weber, too, bestowed warm encomiums upon the opera, but the public did not entertain the same views of its merit. "Jephthah" had no elements of popularity, and was considered a failure. Discouraged by this reception, and at the same time impressed by the genius of Hummel, Meyerbeer now made his début as a pianist at Vienna, and with such brilliant success that he seemed destined to eclipse the fame of all contemporary artists. The court of Vienna, however, commissioned him to compose an opera, and he soon produced *Die beiden Khalifen*, which was no more successful than "Jephthah," both operas being totally opposite to the popular taste, which at that time was delighted by the genius of Rossini and Italian music generally. His friend Salieri consoled him, and prevailed upon him to visit Italy. Meyerbeer on his arrival there witnessed the performance of Rossini's "Tancred," and his enthusiasm for the Italian school now became, to the great regret of Weber, as great as his aversion for it had formerly been. Determined to cultivate his taste for melody, in which he had been deficient, he began to imitate the Italian style, and composed in rapid succession a series of operas, which were almost all favorably received. His *Romilda e Costanza* was performed in Padua in 1818; his *Semiramide riconosciuta*, after Metastasio, in Turin in 1819; and his *Emma di Resburgo*, based upon the same subject as Méhul's "Helen," in Venice in 1820, in the same season with Rossini's *Eduardo e Cristina*, the productions of the German and Italian masters receiving the same share of enthusiastic applause, and the former establishing Meyerbeer's fame. This new opera was translated into German and performed in the principal opera houses of his native country. Weber, however, opposing the Italian style adopted by his friend, caused "The Two Caliphs" to be performed at the German theatre of Dresden, while "Emma" was given to full houses in the Italian opera; but subsequently he was the first to bring Meyerbeer's Italian operas upon the stage in Dresden, paying the utmost attention to the *mise en scène*. In the mean time "Emma" had been received with great enthusiasm by the fastidious audiences of the Scala in Milan, and paved the way for the favorable reception there

of his next opera, "Margaret of Anjou" (1822), in which Levasseur made his début on the Italian stage. This was succeeded by *L'esule di Granata* (1823), the principal parts of which were written for Lablache and Pisaroni. But the procrastination in its performance, which did not take place before the carnival of that year, proved fatal to its reception. The 1st act was hissed, and the 2d act would have shared the same fate if it had not been for a duet admirably sung by Lablache and Pisaroni. Subsequently, however, the opera proved successful. "Almanzor" was also composed in 1822, and intended for the opera of Rome; but owing to the illness of Caroline Bassi, who was to take the principal part, it was never brought out. The *Crociato* was given in Venice at the end of 1825, and at the close of the performance Meyerbeer was called before the curtain and crowned amid the plaudits of the audience. He now made the tour of the different Italian cities, in order to attend personally to the production of his works. The *Crociato* may be taken as the best and most individual of his productions up to that time, the style of which had been marked by a successive improvement. This opera is logically written as regards dramatic harmony, and imitates the vocal Italian phraseology of the period. The melodies are not wanting in artistic perception, and possess the indispensable elements of fluency only found to perfection in the Italian school; yet they are deficient in several respects, and the *Crociato* cannot rank as a work of essential genius. It formed, however, a turning point in Meyerbeer's career, M. de Laroche-foucault inviting him to Paris (1826), where the *Crociato* was received with considerable favor.—Paris now became the head-quarters of the composer, but for the first two years of his residence there he was induced to suspend his musical labors by his marriage and by the successive death of two infant children. In 1826 he composed his *Robert le diable*, which he sold in July, 1830, to M. Lubbert, director of the grand opera, and which made the fortune of his successor, M. Véron. After many rehearsals it was at length brought out in Nov. 1831. The excitement which it created was perhaps unparalleled in the history of the Parisian stage. It combined in a singular degree oriental gorgeousness, German thoughtfulness, French vivacity, and Italian brilliancy, and exhibited a breadth and depth of genius for which the preceding works of the composer, with the exception of some parts of the *Crociato*, had hardly prepared the public. The enthusiasm which greeted it in Paris was shared by all Europe, although it found perhaps more admirers in Germany and France than in other countries. The Germans especially were fascinated by an opera which in some respects reminded them of Goethe's "Faust," and which combined in so remarkable a degree the convivial, picturesque, pathetic, and supernatural elements. The chivalric strains of Robert, the touch-

ing Normandy song of Alice, the thrilling scene at the cross between Bertram and Alice, the ghostly effect of the rising of the nuns from the graves, and the pathos and loftiness of the closing act, contained powerful attractions for high and low; the most popular airs were soon transferred from the stage to the streets, and sung in the taverns. Jenny Lind won her brightest laurels in London by her personification of Alice, and Formes invested Bertram with an intellectuality almost equalling that of Mephistopheles. The melodies of "Robert," the best which Meyerbeer has yet produced, are in the main formed upon the style of Rossini, with certain changes. It has Weber's supernaturalism and the developed orchestration of the period, with the extensions proper to a long subject fully handled. The keen and subtle intellectuality of the composer is revealed throughout the whole work in his effort to make it in every sense acceptable to Parisian audiences. Hence his adoption of the extended musico-dramatical form, so popular in France; his attention to effective contrasts and sequences, which the French dramatists and lyrical composers treat with such consummate skill; his introduction of a vast range and variety of scenic accessories; the sonority of the orchestra, so much insisted upon at the grand opera; and the selection of a libretto by Scribe, which rivets the attention of the audience through the whole of 5 long acts, without for a moment abating in interest.—Meyerbeer reached the climax of his fame by his opera *Les Huguenots*. The feelings of enthusiasm which this work elicited on its first appearance in Paris in March, 1836, have been gaining in strength ever since; and even in Berlin, where his productions had been subjected to the adverse criticism of jealous rivals and of antagonistic schools of music, all depreciating voices were hushed by the "Huguenots," and the friends and foes of the composer became for the first time unanimous in their admiration of his genius. The dramatic character of the "Huguenots" is not surpassed by any work of the lyrical stage, and the strife between the great religious parties in France has never before been portrayed with the graphic power and the thrilling effect which characterized its plot. The creation of the character of Marcel, and of the music suitable to it, would have been alone sufficient to immortalize Meyerbeer; but the whole opera abounds with scenes and incidents which hold the senses of the audience captive by the most remarkable instrumental and vocal effects, and which at the same time engross the mind and the imagination by historical associations full of picturesque splendor. The creation of the poignards and the duet between Raoul and Valentine in the 4th act constitute perhaps the crowning dramatic glory of a work, almost every part of which is crowded with musical, intellectual, and scenic beauties. The "Huguenots" is, above all, to be regarded as one of the first of the operatic achievements which derive their inspiration from the records of his-

tory; and it contributed to inaugurate the era of the lyrico-historic drama, in which the greatest effects of which the musical and dramatic stage and its accessories are capable are used for the purpose of illustrating the most momentous conflicts of mankind. The influence of the "Huguenots," as a herald of this new era of musical art, can perhaps not yet be fully estimated. It invested operatic entertainment with the dignity of the historic muse and the graces of dramatic literature.—Like most great works, those of Meyerbeer require time in their elaboration, and 13 years elapsed before his next opera, *Le prophète*, was ripe for performance. It appeared at length in 1849, and at once took a high place as a worthy successor of the "Huguenots," although of much less imposing character in its historic groundwork and in its general effect. It shows, however, the same largeness of musical and artistic treatment, and as a lyrical drama it derives great beauty from the admirable manner in which the maternal love of Fides is placed in contrast with the religious frenzy of her son, the prophet of Leyden. The scores in this opera, as in Meyerbeer's other works, are wonderful in their elaboration, and may be commended to students for their careful dramatic portraiture, in which the orchestra is made to echo or anticipate the characterization of the scene. The extraordinary labor bestowed upon the *mise en scène* of the "Prophet" has been deemed superfluous by several critics, who regard this excessive elaboration of external effects as derogatory to the genius of the composer and to the intrinsic merits of his works. (See Schladebach, *Meyerbeer's Prophet*, Dresden, 1850.)—The "Prophet" has been followed by *Pierre le Grand* (*L'étoile du nord*, 1854), and "Dinorah" (*Le pardon de Ploermel*, 1858). The former of these shows the versatility of the author, though its success cannot be compared with that of its great predecessors. "Dinorah," which treats a rustic and pastoral theme, is variously criticized in Europe, and unfavorably as regards melody. Meyerbeer has published a great number of miscellaneous musical compositions, among which are *Le camp de Silesie*, an opera produced at Berlin; a *Stabat*, a *Miserere*, a *Te Deum*, 8 of Klopstock's canticles, &c. One of his most finished artistic efforts is the music which he composed for the drama of "Struensee," by his late brother Michael Beer. Meyerbeer has long been engaged on a new opera, called *L'Africain*.

MEZERA Y, FRANÇOIS EUDES DE, a French historian, born at Rye, in Lower Normandy, in 1610, died in Paris in 1688. He served for two campaigns as commissary in the army, after which he wrote his *Histoire de France*, the 1st volume of which appeared in 1648, and the remaining 2 in 1646 and 1651. The king conferred upon the author a pension of 4,000 livres, and the title of historiographer royal; but in 1668 he forfeited his pension by publishing an abridgment of his *Histoire* which contained some severe reflections on French taxation. In

1646 he had been elected a member of the French academy; and in 1675 he became its perpetual secretary. He was a man of eccentric character, writing even *à la lueur* and in summer by candle light, and so negligent of his person that on one occasion he was arrested as a pauper. His history of France has been continued down to 1830 (Paris, 1889).

MEZQUITE, the Mexican name of two kinds of shrubs bearing pods filled with pulp. They are leguminous plants in their natural characters, and belong to that vast and highly useful order. The common mezquite is the *algarobia glandulosa* of Dr. Torrey, a small, woody shrub resembling the honey locust, but, unlike it, the stems are often decumbent. It is armed with straight spines an inch or more in length. Its leaves are bipinnate and furnished with minute stipules, the common petioles terminating in a spinular point, a small gland between the basis of the pinnæ; leaflets $\frac{1}{2}$ to 1 inch or more in length, obtuse, mucronate. The pod or legume is about 6 inches long, straight or a little curved, slightly compressed. The pods have been used for food. In dry seasons the mezquite exudes a large quantity of valuable gum, similar to gum Arabic and gum Senegal. This species is described and figured in the "Annals of the Lyceum of New York," vol. ii. p. 192. The curly mezquite (*Strombosarpa pubescens*, Gray) is also called screw mezquite, screw bean, and tournil. A figure is to be seen in Fremont's "Report" under the name of *prosopis odorata* (Torrey). This shrub is of great value in the wild and desert lands of the far West, as may be noticed in the "Report" of the exploration for a Pacific railroad route, where frequent mention is made of its occurrence near springs of water with willow bushes. It constitutes one of the principal timber trees or shrubs in the Santa Maria valley; and on the route to the Colorado desert the Indian squaws were seen gathering the mezquite beans from the numerous shrubs which there abound. These beans or seeds are ovate, kidney-shaped, compressed, very smooth and hard, with a thin albumen, and are enclosed in pods spirally twisted into compact, rigid cylinders, which are from 1 to 1 $\frac{1}{2}$ inch long, and the sarcocarp of which is also pulpy and nutritious.

MEZQUITE GUM. See GUM, vol. viii. p. 569.

MEZZOFANTI, GIUSEPPE GASPARD, an Italian linguist, born in Bologna, Sept. 17, 1774, died in Rome, March 15, 1849. He was originally destined for his father's trade, that of a carpenter; but while attending one of the free schools of the Fathers of the Oratory in Bologna, a priest of the congregation observed his precocious talents, and enabled him to be educated for the church, and he was ordained in 1797. He was gifted with an extraordinary memory, and before the close of his university career had made himself master of the Latin, Greek, Hebrew, Arabic, Coptic, Spanish, French, German, and Swedish languages. At the age of 23 he was appointed professor of Arabic at Bologna; but on the annexation of that city to

the Cisalpine republic, he was removed from his professorship for refusing to take the oaths to the new constitution. After the conclusion of the concordat between Pius VII. and Napoleon, Mezzofanti was restored to the university, and named professor of oriental languages. The suppression of his professorship in 1808 reduced him to great distress, leaving him mainly dependent for his own support and that of his sister's children on the precarious income derived from private tuition. The wars of which N. Italy was so long the theatre had afforded him many opportunities of extending his knowledge as a linguist. In the hospital of Bologna, to which he had attached himself as volunteer chaplain, were to be met invalids from most of the countries of central and eastern Europe—Germans, Hungarians, Bohemians, Wallachs, Servians, Russians, Poles, and Croats; and while ministering to these, he acquired by conversation with them a knowledge of their respective languages. He was also in the habit of repairing to the hotels whenever strangers arrived, for the purpose of studying the peculiarities of their phraseology and pronunciation. In 1812 he was appointed assistant librarian, and in 1815 head librarian of the university of Bologna. After the conclusion of peace, his reputation as a linguist rapidly extended. Mr. Stewart Rose reported that, in 1817, he could read 20 languages, and write 18. Lord Byron, whom he is said to have beaten in talking English slang, pronounced him a monster of languages, a Briareus of parts of speech, and a walking polyglot. Lady Morgan, in 1822, stated that rumor ascribed to him the knowledge of 40 languages, though his own modesty claimed only a superficial acquaintance with that number. Having gone to Rome in 1832 as one of a deputation sent by the Bolognese to congratulate Gregory XVI. on his election, he was induced by the pope to settle there, and to accept a prebend in the church of St. John Lateran. This appointment he soon after exchanged for a canonry in St. Peter's, and in 1833 he succeeded Angelo Mai as chief keeper of the Vatican library, an office which he held till 1838, when conjointly with Mai he was elevated to the cardinalship. His residence in Rome gave a new impulse to his linguistic studies. To his former acquisitions he here added a knowledge of Irish, Welsh, Lappish, Sanscrit, Persian, Georgian, Armenian, Chinese, and several Hamitic tongues, all of which he is said to have spoken with extraordinary precision and fluency. His familiarity with the dialectical varieties and local idioms of the principal languages, as well as with their respective literatures, and his power of instantly passing from one to another in conversation, were almost incredible. At the time of his death he is said to have been acquainted with 114 languages. Mezzofanti never held any office of state, and though a learned theologian and canonist, he is almost unknown as an author, his only published work being a panegyrical "Memoir of Father Emanuel da Ponte," a friend

and brother professor (Bologna, 1820). He was a man of great virtue and modesty, open-hearted, amiable, and remarkably abstemious. His life has been written by O. W. Russell, D.D., principal of Maynooth college, (London, 1858).

MEZZOTINTO. See ENGRAVING, vol. vii p. 210.

MIAKO, the ecclesiastical capital of Japan, and residence of the mikado or nominal emperor, situated in the S. W. part of the island of Nippon, in lat. $35^{\circ} 6' N.$, long. $135^{\circ} 38' E.$, 25 m. W. S. W. from Yeddo. It lies in a well cultivated plain in the province of Yamato, and is surrounded by hills from which spring many small rivers, and on whose declivities are magnificent temples and vast gardens. The city is 4 m. in length and 8 in breadth. Three shallow streams, the largest of which is the outlet of the lake of Oitz, enter on its E. side, and in the middle unite to form one river, over which near the place of junction there is a bridge 60 feet in length; the united stream flows through the city and passes out on the W. side. The streets are narrow and straight, crossing each other at right angles. The houses are two stories in height, and are built of wood, plaster, and clay, with shingled roofs. In the western quarter is a large castle built of freestone, in which a garrison is always maintained. In the city and its neighborhood are numerous temples and monasteries, the former being the most magnificent in Japan. Don Rodrigo de Vivero, the Spanish governor of Manila, who visited Miako in 1608, was told that it then contained 5,000 temples. He describes one in which was an immense bronze image of Buddha, the construction of which was begun by the tycoon in 1602. He says: "I ordered one of my men to measure the thumb of the right hand of the statue, although he was a person of the ordinary size; he could not quite encircle it with both arms. But the size of the statue is not its only merit. The feet, hands, mouth, eyes, forehead, and all the features are as perfect and as expressive as the most accomplished painter could make a portrait. When I first visited this temple, the statue was unfinished; more than 10,000 men were employed upon it. The devil could not resist to the emperor a surer expedient to get at his immense wealth." This colossal statue was melted down in 1662, after it had been injured by an earthquake in 1662, after it had been melted down and a substitute prepared of wood gilded. Kämpfer, who was at Miako in 1691, describes the temple which contains the image as enclosed by a high wall of freestone, some of the blocks of which were 12 feet square. A stone staircase of 8 steps led up to the temple, on either side of which stood a statue of Buddha 24 feet high with the face of a woman, and otherwise well proportioned, black and naked, and placed on a pedestal 4 feet high. Within the gateway were 16 statues of Buddha on each side for lamps, and on the inner side of the enclosing wall was a spacious gallery with a roof supported by two rows of pillars, 12 feet high and 12 feet distant from each other.

Opposite the gateway in the middle of the court stood the temple, much the loftiest structure which Kämpfer had seen in Japan, with a double roof supported by 94 immense wooden pillars, 9 feet in diameter. The floor of the temple was paved with square flags of marble. There was nothing inside but the great image of Buddha sitting on a *terete* or lotus flower, supported by another flower of which the leaves were turned upward, the two being raised about 12 feet from the floor. The idol was gilt all over, had long ears, curled hair, and a crown on the head which appeared through the window over the first roof of the temple. The shoulders were so broad as to reach from one pillar to another, a distance of 80 feet. In front of this temple is an edifice containing a bell, which is described in the Japanese guide books as 17 feet 2½ inches high, and weighing 1,700,000 Japanese catties, equal to 2,066,000 lbs. English, a weight 5 times greater than that of the famous bell at Moscow. Kämpfer, however, who had seen the great bell at Moscow, describes this Japanese bell as inferior in size to that, and as being rough, ill cast, and ill shaped. It was sounded by striking it on the outside with a large wooden mallet. Another temple, dedicated to Quanwon, was very long in proportion to its breadth. In the centre was a gigantic image of Quanwon, with 36 arms. Sixteen black images larger than life stood round it, and on each side two rows of gilt idols with 20 arms each. On either side of the temple, running from end to end, were 10 platforms rising like steps one behind the other, on each of which stood 50 images of Quanwon as large as life—1,000 in all, each on its separate pedestal, so arranged as to stand in rows of 5, one behind the other, and all visible at the same time, each with its 20 hands. On the heads and hands of all these are placed smaller idols to the number of 40 or more. The whole number of images is stated by the Japanese to be 38,000.—The N. E. quarter of Miako is the residence of the emperor of Japan, the dairi or mikado as he is called. This quarter is of great extent, and is separated from the rest of the city by a wall and ditch. It comprises about a dozen streets, in which dwell the officers and attendants of the imperial court, and a vast multitude of persons who all claim to be of imperial blood, and to be descended from Syn Mu, the first of the emperors. Many of these nobles, however, are extremely poor, and support themselves by various handicrafts. All the revenues of Miako and its 5 dependent provinces are assigned to the support of the mikado and his court; and the tycoon, the real ruler of the empire, makes for the same purpose an annual allowance from the treasury at Yeddo. From the latest accounts, however, it appears that the court of the mikado is often reduced to great straits for want of money. Miako is the principal manufacturing and commercial city of Japan. Money is coined there, and there are extensive works in copper, iron, and other metals, particularly

in steel, the best tempered sword blades and other arms being made here. The city is famous also for its manufacture of gold and silver stuffs, rich dresses, furniture, toys, carvings, musical instruments, pictures, and *etc.* It is the centre of the internal trade of the empire, which is carried on here by means of great fairs, at which immense quantities of tea, silk goods, porcelain, rice, lacquered ware, and other commodities are sold. Miako is also the chief seat of learning and literature, most of the books in circulation in the empire being written and printed here. The people are noted for their intelligence and polished manners, and at the same time for their profligacy.—We have no recent statement of the population. According to Kämpfer, the result of a census in his day was a total population of 529,720, of whom 52,169 were ecclesiastics. The number of houses was 138,979, and there were 1,858 streets, 87 bridges, and 137 palaces. There is reason to believe that its present population (1860) is not far from 1,000,000.

MIALL, EDWARD, an English reformer and journalist, born in Portsmouth in 1809. He was educated at the Protestant dissenters' college at Wymondley, Herts, and for several years officiated as an Independent minister at Ware and Leicester. In 1841 he established the "Nonconformist" newspaper in London, in the interests of the "anti-state-church" party, and has since continued to be its editor and proprietor. After several unsuccessful attempts to enter parliament, he was returned for Rochdale in 1852, but lost his seat in the general election of 1857, and has not since been a member. He has published the "Nonconformist's Sketch Book," and "The British Churches in relation to the British People," in which his opposition to ecclesiastical establishments and endowments is vigorously expressed.

MIAMI. I. A. W. co. of Ohio, intersected by the Miami river and drained by its branches; area, about 400 sq. m.; pop. in 1850, 24,996. The surface in the E. part is rolling and in the W. more level, and the soil very fertile. The productions in 1850 were 1,129,456 bushels of Indian corn, 222,122 of wheat, 163,987 of oats, and 71,430 lbs. of wool. There were 23 grist mills, 39 saw mills, 2 iron foundries, 3 woollen factories, 10 tanneries, 43 churches, and 10,579 pupils attending public schools. It is intersected by the Miami and Erie canal, and by the Columbus and Indianapolis and the Dayton and Michigan railroads, the latter passing through the capital, Troy. II. A. N. co. of Ind., intersected by the Wabash and Eel rivers; area, 384 sq. m.; pop. in 1850, 11,304. It has a generally level surface, with elevations near the streams, and a fertile soil. The productions in 1850 were 548,838 bushels of Indian corn, 114,454 of wheat, 29,569 of oats, and 17,511 lbs. of wool. There were 10 grist mills, 13 saw mills, 4 tanneries, 13 churches, and 2,500 pupils attending public schools. The Toledo and Wabash railroad intersects the county, passing through the capi-

tal, Peru, which is connected with Indianapolis by the Peru and Indianapolis railroad.

MIAMI, a river of Ohio, which rises in Hardin co., and flows S. and S. W. for a distance estimated at 150 m., passing Troy, Dayton, and Hamilton, falls into the Ohio river at the S. W. corner of the state, 20 m. W. of Cincinnati. It is a rapid stream, passing through a picturesque and fertile country, and admits of navigation for only a portion of its length. Its principal branches are the West branch, the Mad and the Whitewater rivers. The Miami canal runs along the river for about 70 miles, and together they furnish extensive power for manufacturing purposes.—This river is sometimes called the Great Miami, in distinction from the Little Miami, which rises in Madison co., and after a S. W. course of about 100 m., nearly parallel to the former, falls into the Ohio 6 m. E. of Cincinnati. It is skirted for the greater part of its course by the Little Miami railroad, connecting Xenia and Cincinnati.

MIAMI UNIVERSITY, a seat of learning at Oxford, Butler co., Ohio, 88 m. N. W. from Cincinnati. In 1788 J. C. Symmes purchased from the United States 1,000,000 acres of land, bounded S. by the Ohio river, E. by the Little Miami, and W. by the Great Miami. One condition of this purchase was, that a full township, 36 miles square, should be set apart "for the endowment of an academy and other seminaries of learning." This condition was not complied with; but as the prospect of the establishment of a university within the bounds of Symmes's purchase had induced many to settle there, in 1803 congress ceded to the state of Ohio the township of Oxford, to be held in trust for educational purposes. The university was incorporated in 1809. The lands are leased for 99 years (renewable for ever without revaluation), subject to an annual quitrent of 6 per cent. on the purchase money, and yield an income of nearly \$6,000. The government of the institution is vested in a board of 18 trustees, appointed by the governor of the state with the consent of the senate, for the term of 9 years, 6 of whom retire every third year. The faculty consists of a president and 7 instructors. There are 4 college buildings: one 86 by 60 feet and 3 stories high, with a wing 40 feet square; the other 2 are each 100 by 40 feet, and 3 stories high. These buildings are plain, old-fashioned, and substantial structures, situated in a field of 60 acres shaded by the native forest. A grammar school was commenced in 1818, and in Nov. 1824, the college was opened under the presidency of the Rev. R. H. Bishop, D.D., a graduate of Edinburgh university. Dr. Bishop resigned in 1840, and served as professor of history till 1845. He was succeeded in the presidency by the Rev. George Junkin, D.D., previously president of Lafayette college, Penn., and now of Washington college, Va. He resigned in 1844, and was succeeded by the Rev. E. D. McMaster, D.D.; on whose resignation in 1849, the Rev. W. C. Anderson, D.D., was ap-

pointed, who was succeeded in 1854 by the Rev. J. W. Hall, D.D. The first class, consisting of 12 members, was graduated in 1826; the whole number of graduates up to 1859 was 674, of whom nearly one third have entered the ministry. The number of students in 1859 was 127. The library contains 7,500 vols.

MIASMA. See MALARIA.

MICA (Lat. *mico*, to shine), in mineralogy, the name of a group of the silicates, distinguished by their remarkable lamellar structure, the elasticity of their laminae, and their half metallic lustre. The mineral crystallizes in right rhomboidal prisms of 120° , which separate with the greatest facility in folia parallel with the base of the crystal. These may be subdivided till many thousand plates are required to make the thickness of an inch. The plates are sometimes found of an area of several square feet. They are usually transparent, elastic, and tough. The colors are various; the most common are silvery white, grayish green, red, and black. The hardness of the mineral is 2 to 2.5; specific gravity 2.65 to 3. The different species are distinguished partly by their different optical characters as well as by their differences of composition. They present 2 axes of double refraction, which, in the species designated by Dana as muscovite, and commonly known as Muscovy glass, vary in apparent inclination between 44° and 75° ; in the phlogopites, called also rhombic mica and magnesia mica in part, from 5° to 20° ; and in the biotites below 5° . Prof. B. Silliman, jr., observes that the muscovites are confined to granitic and other igneous rocks, and the phlogopites to granular limestone and serpentine. The former generally contain potash or lithia and little magnesia, and the latter contain magnesia, and often but little alkali. The composition of the most common micas, according to Dufrénoy, is from 45 to 50 per cent. of silica, 32 to 38 of alumina, 10 to 12 of alkali (rarely soda), and 2 to 4 of fluoric acid. He considers the differences of composition too great to admit of any general formula. The micas are silico-fluorates, containing, beside silica and fluorine, alumina, iron, magnesia, potash, and lithia, the magnesia generally failing in the varieties found in the granitic rocks. Lepidolite is a species distinguished for its occurrence usually in granular masses made up of foliated scales of reddish color, violet gray, yellowish, or whitish. Muscovite, the most familiar form of mica, is a constituent of granite, gneiss, mica slate, and some other kindred rocks. It is found both disseminated and in veins, and in many of the stratified rocks it is an incidental constituent derived from the destruction of the original formations to which it belonged. The mineral is thus seen to be very generally distributed; but certain localities are distinguished for the production of large plates of it. In Siberia they have been found more than 8 feet across, and they have been obtained of great size in Sweden and Norway. This is also the case at Acworth, Georgia, and Alstead, N. H.; and mica has also been

found in some of the other states and in Canada sufficiently large to be quarried for economical purposes. Mica is used mostly for the doors of stoves and the sides of lanterns, for which it is well adapted by its transparency and refractory character. It has been employed as a substitute for window glass, and its toughness recommends it for this purpose on board vessels of war, in which the concussion from the discharge of heavy guns would endanger the fracturing of glass. It is also serviceable for holding small objects for microscopic examination. The value of good plates is about \$1 per lb.

MICA SLATE, a rock consisting of mica and quartz, and sometimes feldspar, in which the mica predominates, and by its arrangement in parallel planes gives to the aggregate a foliated structure.

MICAH, one of the 12 minor prophets, who, according to the testimony of his book (i. 1), prophesied in the days of Jotham, Ahaz, and Hezekiah, kings of Judah (759-699 B. C.). He was a native of Moresheth of Gath. The prophecy of Micah consists of two parts, the first of which terminates with chapter v. It begins with a sublime theophany, the descent of the Lord to judge the nations of the earth, and then predicts the captivity of Israel, the fall of Judah, the destruction of Jerusalem, the expatriation of the Jews, their future return, and the celebrity of the temple of Zion. Other bloody and glorious wars are seen in the perspective, and after many calamities a ruler is seen to come forth from Bethlehem (v. 2), which is one of the most important prophecies, regarded from a theological point of view. The second part consists of a dialogue or contest between the Lord and his people. The style of Micah is sublime and vehement, and in this respect he is not inferior to any other prophet of the Old Testament. One of the principal works on Micah is that of Caspari, *Micah der Moraschite und seine prophetische Schrift* (Christiania, 1851).—Micah, or Micaiah, was also the name of another prophet mentioned in the history of Ahab, king of Israel.

MICHAEL (Heb., who is as God?), the angel who had special charge of the Israelites as a nation (Dan. x. 18, 28), who disputed with Satan about the body of Moses (Jude 9), and who with his angels carried on war with Satan and his angels in the upper regions (Rev. xii. 7-9). The Jews regarded Michael as one of the archangels, and the Christian church early adopted this view. The representation of Michael, sword in hand, conquering the dragon, became a favorite symbol in the Roman Catholic church. A festival of St. Michael was introduced as early as 480 by Pope Felix, and it was retained also in the Lutheran church. Mohammedans regard Michael likewise as one of the archangels, and as guardian angel of the Jews.

MICHAEL ANGELO. See ANGELO.

MICHAELIS, JOHANN DAVID, a German biblical scholar and critic, born in Halle, Feb. 27, 1717, died in Göttingen, Oct. 22, 1791. He was

graduated at the university of his native city in 1739, visited England, and in 1743 returned to Halle, and began to deliver lectures on the historical books of the Old Testament. In 1745 he was appointed professor extraordinary, and soon after regular professor of philosophy at Göttingen. For nearly 20 years he edited the *Göttinger gelehrte Anzeigen*. His principal works are: a translation of the Hebrew Bible; "Introduction to the New Testament," translated into English by Bishop Marsh; and *Das Mosaische Recht* (2d ed., 5 vols., Göttingen, 1776-'89), translated into English by Dr. Alexander Smith, under the title of "Commentaries on the Laws of Moses," in 1814.

MICHAELMAS, the feast of St. Michael the Archangel, Sept. 29. It is more celebrated for popular customs connected with it than for any peculiar religious observance. It was an old custom in England to mark the day by electing civil magistrates, perhaps in allusion to the analogy between the superintendence of magistrates and that of guardian angels, of whom St. Michael was reputed the prince. A more famous custom is that of eating roast goose, the origin of which has long exercised the wisdom of antiquaries. The traditional Michaelmas goose has been traced at least as far back as the 10th year of Edward IV.; and it is said that one of the strongest objections of the English commonalty to the reformation of the calendar was based on the confusion which would follow if Michaelmas day was not celebrated when stubble geese are in their highest perfection. There is an old proverb: "If you eat goose on Michaelmas day, you will never want money all the year round."

MICHATOYAT, RIO. See GUATEMALA, vol. viii. p. 540.

MICHAUD, JOSEPH, a French poet and historian, born at Albens, Savoy, June 19, 1767, died in Passy, Sept. 30, 1839. He commenced his literary career in Paris in 1791 by the publication of a *Voyage littéraire* to Mont Blanc and the adjoining regions, followed by an oriental tale entitled *Origine poétique des mines d'or et d'argent*, neither of which attracted much notice. He next became a defender of the monarchy; and for publishing an anti-revolutionary satire entitled *Déclaration des droits de l'homme*, he was obliged for a time to conceal himself. In Sept. 1792, he established *La quotidienne*, a daily journal in the royalist interest, the character of the articles in which caused him to be arrested and condemned to death. The efforts of his friend Giguet preserved him from the guillotine, and he was executed in effigy only. Adhering steadily to his opinions under the directory, he was banished after the 18th Fructidor (Sept. 4, 1797), and took refuge among the Jura mountains, whence after a two years' exile, he returned to France in Nov. 1799. Among the fruits of his absence was a poem, the *Printemps d'un proscrit* (Paris, 1803), which went through many editions. He opposed the consulate with no less acrimony than he had

attacked the convention and the directory, and for an anonymous pamphlet, the *Adieux à Bonaparte* (Paris, 1800), he was confined for a short time in the Temple. In 1801 appeared his first historical work, *Histoire des progrès et de la chute de l'empire de Mysore, sous le règne d'Hyder Ali et de Tippe Saïb* (2 vols. 8vo.), followed in the succeeding year by the *Biographie moderne* (4 vols. 8vo., Leipsic), printed in Paris by the brothers Michaud, a publishing firm established at the commencement of the century by himself, his brother Louis Gabriel, and Giguet. This publication was the germ of the later and more elaborate work, the *Biographie universelle*, published by the same house. His royalist views meanwhile began to yield to the force of circumstances, and in 1811 he addressed a congratulatory poem to Napoleon on occasion of his marriage to Maria Louisa, under the title of *Fragment d'un treizième livre de l'Énéide*, and another in 1812 commemorating the birth of the king of Rome. The year 1812 witnessed the appearance of the 1st volume of his most important work, the *Histoire des croisades*, which went through 5 editions in his lifetime, the last being in 1838 (6 vols. 8vo.), has been translated into the principal languages of Europe, and is an enduring monument of his industry and ability. He published an abridgment of it (2 vols. 12mo., 1838), and in further illustration of the subject produced the *Bibliothèque des croisades* (4 vols.), and *Correspondance d'Orient* (7 vols.), the latter being a record of his extensive travels in company with his pupil, Poujoulat, through those portions of the East traversed by the crusaders. After the overthrow of the empire Michaud reestablished the *Quotidienn*e, but during the Hundred Days it lost its original character, and became a mere vehicle of news. He subsequently published an account of the Hundred Days, of little historical value, which passed through 27 editions, and continued until the close of his life, in spite of feeble health, to devote himself to historical researches. Among his last publications were an edition of Hénault's *Abrégé chronologique de l'histoire de France*, with a continuation to July, 1830, and a *Collection de mémoires pour servir à l'histoire de France*, which was commenced in 1836, in conjunction with Poujoulat, and published in 34 vols. 8vo. The work, however, with which his name has been most popularly associated, is the *Biographie universelle*, published between 1811 and 1828, and which, with its supplement, 1834-'40, comprises 85 vols. 8vo. He was a member of the French academy and of the academy of belles-lettres, and held other positions of honor and emolument.—LOUIS GABRIEL, brother of the preceding, born in Bourg-en-Bresse in 1772, died at Ternay, near Paris, in March, 1858. He accompanied his brother to Paris, and with him founded the publishing house of Michaud brothers, from which have issued some of the most important historical and biographical works of the century. Of the *Biographie universelle*,

which has been sometimes termed the *Biographie Michaud*, a considerable portion was written by him, and he subsequently carried on a successful suit against the Messrs. Didot, who had appropriated the title to their work, since named *Biographie générale*, now in course of publication. In 1854 a new and greatly enlarged edition of the *Biographie universelle* was commenced under the auspices of M. Michaud, which is nearly half completed. He published in addition a *Tableau historique et raisonné des premiers guerres de Bonaparte*, and a variety of notes and prefaces to books edited by him.

MICHAUX, ANDRÉ, a French botanist, born near Versailles, March 7, 1746, died in Madagascar in 1802. After enriching the *jardin des plantes* with many specimens collected during expeditions in England, the Pyrénées, and Spain, he was sent to Persia in 1782 by Monsieur, afterward Louis XVIII. In the "garden of Semiramis" near Bagdad he discovered a Persepolitan monument, which he sent to the cabinet of antiquities in the royal library at Paris. Returning to France with a valuable botanical collection, he was commissioned by the government in 1785 to make a journey through North America. He traversed a great part of the continent from Florida to Hudson's bay, established botanical gardens in Charleston and New York, and collected and sent home an immense quantity of plants and seeds. The government allowance for the expense of this undertaking having ceased at the revolution, he made use of his private purse until it was exhausted. On his voyage home he was shipwrecked and lost all that he possessed except 4 cases of specimens. In 1800 he joined the expedition to New Holland under Capt. Baudin, but left it at the Isle of France, and went to Madagascar. He left a *Histoire des chênes de l'Amérique Septentrionale* (fol., Paris, 1801), and *Flora Borealis Americana* (3 vols. 8vo., 1803).—FRANÇOIS ANDRÉ, a French botanist, son of the preceding, born in Versailles in 1770. He was employed by the French government on a scientific mission to North America, to decide what species of the forest trees of that country might profitably be introduced into Europe, and made 8 voyages to the United States, whence he sent to France large quantities of valuable seeds. His principal work is the "History of the Forest Trees of North America" (3 vols. 8vo., Paris, 1810-'13), of which an English translation was published in Philadelphia in 1817 in 5 vols. 8vo., with 150 colored engravings. He also published a treatise "On the Naturalization of Forest Trees in France" (8vo., Paris, 1805), "Journey to the West of the Alleghany Mountains" (8vo., Paris, 1804; London, 1805), and "A Notice of the Bermudas" (4to., Paris, 1806).

MICHEL, FRANÇOISQUE, a French author and archaeologist, born in Lyons, Feb. 18, 1809. He commenced his literary career in Paris as a writer for the journals, and in 1832 published two historical novels. His chief attention, how-

ever, was given to philological researches, and between 1830 and 1833 he edited a number of publications written in mediæval French, including *La chronique de Du Guesclin*, *Les chansons de Coucy*, *Le lai d'Havelock le Danois*, &c. In 1835 he was commissioned by Guizot, then minister, to make researches into early French history and literature among the libraries of England, and in 1839 he was appointed professor of foreign literature in the faculty of Bordeaux. Between 1834 and 1842 he published in London or Paris upward of 80 works in French, Saxon, or English, written between the 11th and 14th centuries, many of which were then printed for the first time. Among the most important from an archæological point of view are: the "Romance of Eustache Le-moine" (8vo., 1834); "Tristan" (2 vols. 12mo., London, 1835); "Anglo-Norman Chronicle" (3 vols. 8vo., Rouen, 1836-'40), illustrating the history of England and Normandy during the 11th and 12th centuries; the "Song of Roland" (8vo., 1837); "Chronicle of the Dukes of Normandy" (4 parts, 1837-'40), by the troubadour Benoît; "Song of the Saxons" (2 vols. 8vo., 1839-'40), a narrative of the life of Wittekind; and "History of the Dukes of Normandy and the Kings of England" (8vo., 1840). He has also produced several original works of considerable erudition, including his *Histoire des races maudites de la France et de l'Espagne* (2 vols. 8vo., 1847); *Le livre d'or des métiers* (2 vols. 8vo., 1851-'4); *Histoire des tissus de soie au moyen âge* (2 vols. 4to., 1852-'4), &c. His last work, *Le pays Basque* (Paris, 1858), has great merit.

MICHELET, JULES, a French historian and miscellaneous writer, born in Paris, Aug. 21, 1798. He is the son of a printer, who zealously provided for his education, and he studied with brilliant success in the collège Charlemagne under Villemain and Leclerc. After travelling in Germany, he was called in 1821 to the chair of history in the collège Rollin, where he was also professor of the ancient languages and of philosophy till 1826, publishing in the period his *Tableau chronologique de l'histoire moderne* (1825) and *Tableaux synchroniques de l'histoire moderne* (1826). In 1827 he was made *maître des conférences* in the normal school, and after the revolution of 1830 received the desirable appointment of chief of the historical section of the archives of France. In that year Guizot, who was diverted from literature to politics, chose him to continue his lectures in the faculty of letters. His reputation was extended by a series of historical works, which secured to him admission in 1838 to the college of France and to the academy of moral sciences. Among his publications were: *Précis de l'histoire moderne* (1828), a work which has become a classic in France, and passed through more than 20 editions; *Introduction à l'histoire universelle* (1831); a translation of Vico's *Scienza nuova*, under the title of *Principes de la philosophie de l'histoire* (1831); *Histoire Romaine* (1831); and *Mémoires de Luther* (1838), consisting al-

most entirely of passages from Luther's writings. In 1833 appeared the first portion of his most important work, not yet completed, the *Histoire de France*. His academical lectures had meantime become distinguished for appeals in favor of democratic ideas and for assaults upon the society of Jesuits, against whom he waged a violent warfare. He embodied these tendencies in 3 books: *Des Jésuites* (1843), in collaboration with Quinet; *Du prêtre, de la femme et de la famille* (1844); and *Du peuple* (1846). No professor of history in the college of France ever attracted a more numerous and sympathetic audience, and the government of Louis Philippe, regarding his attacks on the established order as dangerous, suspended his course. He was restored to his chair after the revolution of 1848, again declined public office as he had done in 1830, and gave to his lectures the design and character of democratic propagandism, till his course was closed by the government of Louis Napoleon in March, 1851. He lost his place in the archives after the *coup d'état* of Dec. 2, 1851, by refusing to take the oath. He published the *Procès des templiers* (2 vols., 1841-'52), a collection of unprinted documents; *Origines du droit Française cherchées dans les symboles et formules du droit universel* (1837), founded on Grimm's work on German antiquities; and *Précis de l'histoire de France jusqu'à la révolution Française* (7th ed., 1842). Since his retirement, he has been a second time married, has continued his historical labors, and has published a series of volumes entitled *L'oiseau* (1856), *L'insecte* (1857), *L'amour* (1858), and *La femme* (1859), remarkable for their poetical and suggestive speculations. The two last, in which physiology and sentiment are oddly intermingled, have been translated into English by J.W. Palmer, M.D. (New York, 1859 and 1860). The last volume of his *Histoire de France* (1860) extends to the revocation of the edict of Nantes. The *Histoire de la révolution Française* (6 vols., 1847-'53), and *Les femmes de la révolution* (2d ed., 1855), form distinct works. His more important publications have all appeared in English. As a historian he excels in picturesqueness of style, in sudden dramatic effects, and in striking though sometimes fantastic generalizations.

MICHELET, KARL LUDWIG, a German philosopher, born in Berlin, Dec. 4, 1801. He belongs to a family exiled from France by the revocation of the edict of Nantes, and was educated in the gymnasium founded by the French colony and in the university of Berlin, where he received the decree of Ph.D. in 1824. The principles contained in his inaugural dissertation were subsequently developed in his *System der philosophischen Moral* (Berlin, 1828). In 1825 he was appointed to the professorship of philology and philosophy in the French gymnasium, which he held for 25 years; and in 1829 he became professor of philosophy also in the university of Berlin. He devoted himself especially to the doctrines of Aristotle, and published *Die*

Éthik des Aristoteles (Berlin, 1827), an edition of the Nicomachean ethics with a Latin commentary (2 vols., 1829-'33), and a memoir entitled *Examen critique du livre d'Aristote, intitulé Métaphysique* (Paris, 1836), which was crowned by the academy of moral and political sciences of Paris. From 1832 to 1842 he was engaged as one of the editors of Hegel's works, in illustration of whose system he wrote *Geschichte der letzten Systeme der Philosophie in Deutschland von Kant bis Hegel* (2 vols., Berlin, 1837-'8); *Entwicklungsgeschichte der neuesten Deutschen Philosophie mit besonderer Rücksicht auf den gegenwärtigen Kampf Schelling's mit der Hegelschen Schule* (1843); and a controversial dissertation, *Schelling und Hegel* (1839). In 1840 appeared his *Anthropologie und Psychologie*, in which in many respects he diverged from Hegelian principles. His own standpoint and tendency are most decisively shown in his *Vorlesungen über die Persönlichkeit Gottes und die Unsterblichkeit der Seele, oder die ewige Persönlichkeit des Geistes* (1841); and *Die Epiphanie der ewigen Persönlichkeit des Geistes* (1844-'52). In the latter, the 3 parts of which he terms a trilogy, he regards the personality of the absolute, the significance of the historical Christ, and the immortality of the soul, as different views of one and the same question. In 1848-'9 he engaged in the discussion of political affairs.

MICHIGAN, one of the western states of the American Union, and the 13th admitted under the federal constitution, situated between lat. 41° 40' and 48° 20' N., and long. 82° 25' and 90° 34' W. It is bounded N. by Lake Superior, which separates it from British America; E. by St. Mary's strait, or river, Lake Huron, St. Clair river, Lake St. Clair, the Detroit river, and Lake Erie; S. by Ohio and Indiana; and W. by Lake Michigan and the Menomonee and Montreal rivers, with the chain of lakes lying between their head waters. The land area of the state is 56,248 sq. m., or 35,995,520 acres, being 1.91 per cent. of the total area of the United States. Beside 19 unorganized it has 54 organized counties, viz.: Allegan, Alpena, Bay, Barry, Berrien, Branch, Calhoun, Cass, Cheboygan, Chippewa, Clinton, Eaton, Emmet, Genesee, Grand Traverse, Gratiot, Hillsdale, Houghton (including Isle Royale), Huron, Ingham, Ionia, Iosco, Isabella, Jackson, Kalamazoo, Kent, Lapeer, Lenawee, Livingston, Macomb, Manistee, Manitou, Marquette, Mason, Mecosta, Michilimackinac, Midland, Monroe, Montcalm, Muskegon, Newaygo, Oakland, Oceana, Ontonagon, Ottawa, Saginaw, Sanilac, Shiawassee, St. Clair, St. Joseph, Tuscola, Van Buren, Washtenaw, Wayne. The principal cities and towns are Lansing, the capital, Detroit, the chief seat of commerce, Ann Arbor, the seat of the state university, Grand Haven, Grand Rapids, Jackson, Kalamazoo, Mackinaw, Marshall, Pontiac, Sault Ste. Marie, and Ypsilanti.—The results of the U. S. census enumerations of the population of Michigan have been as follows:

Census years.	White persons.	Colored persons.	Total population.
1810.....	4,618	144	4,762
1820.....	8,591	298	8,889
1830.....	31,346	298	31,644
1840.....	211,560	707	212,267
1850.....	395,071	2,568	397,639
1860.....	71,364*

A state enumeration in 1854 gave 508,324 white and 8,826 colored; total, 511,720. Decennial increase, 1810-'20, 86.81 per cent.; 1820-'30, 255.65; 1830-'40, 570.9; 1840-'50, 87.84; 1850-'60, 89.21. Density to the square mile in 1850, 7.07; ratio to the total population of the United States, 1.71 per cent. Density to the square mile in 1860, 13.54. In 1850, the white population consisted of 274,465 males and 186,606 females, whose ages were as follows: under 1 year, 10,624; 1 and under 5, 59,615; 5 and under 10, 59,231; 10 and under 15, 49,581; 15 and under 20, 42,534; 20 and under 30, 68,677; 30 and under 40, 51,152; 40 and under 50, 34,221; 50 and under 60, 18,068; 60 and under 70, 8,579; 70 and under 80, 2,793; 80 and under 90, 556; 90 and under 100, 67; 100 and upward, 7; unknown, 120. Deaf and dumb, 124; blind, 125; insane, 132; idiotic, 186. Born in the state, 137,657; from other states, 201,586; in foreign countries, 54,593; and in parts unknown, 1,255. Of the colored population (blacks 1,465, and males 1,118), 1,431 were males and 1,153 females. The number of dwellings was 71,616; of families 72,611. Births of all classes, in 1849-'50, 10,898 (2.74 per cent.); marriages, 4,257 (1.07 per cent.); deaths, 4,515 (1.14 per cent.). Of the total population in 1850, 341,591 (85.91 per cent.) were natives, 54,852 (13.79 per cent.) foreigners, and 1,211 (0.30 per cent.) of race unknown. Of the native-born, 140,645 were born in Michigan, 133,756 in New York, 14,777 in Ohio, 11,113 in Vermont, 9,452 in Pennsylvania, 8,167 in Massachusetts, and 6,751 in Connecticut; and of the foreign-born, 13,450 were born in Ireland, 10,747 in England and Wales, 2,361 in Scotland, 10,281 in Germany, 2,541 in Holland, and 945 in France. Of the male population of the state over 15 years of age (1850) there were employed in commerce, trade, manufactures, mechanic arts, and mining, 22,007; in agriculture, 65,815; in labor not agricultural, 15,662; in the army, 143; in sea and river navigation, 1,220; in law, medicine, and dentistry, 2,007; in other pursuits requiring education, 1,092; in government civil service, 1,092; in domestic service, 220; and in other occupations, 167. The number of persons employed in manufacturing establishments was 9,290.—Michigan consists of two irregular peninsulas which are separated from each other by the upper end of Lakes Michigan and Huron. The upper or northern peninsula comprises about $\frac{1}{3}$ of the area of the state, and is bounded N. by Lake Superior, E. by St. Mary's strait, which divides

* Population of two counties estimated.

it from Canada, S. by Lakes Huron and Michigan, and S. W. by Wisconsin. From its N. W. extremity the Lake Superior shore trends N. E. for a distance of about 160 m. to the end of Keweenaw point, a long peninsula running out into the lake. On the E. side of this point is Keweenaw bay. Thence to White Fish point the coast line presents a regular undulation with scarcely any good harbors. At White Fish point it bends sharply to the S. and afterward to the E., enclosing with the Canada shore the deep basin known as Tequamenon bay, from the head of which flows St. Mary's strait. At the mouth of this strait lie several islands, Drummond's island, which belongs to Michigan, being of considerable size. The Lake Huron shore, extending thence westward to the straits of Mackinaw, is much broken and lined with islets; it is separated from Lake Michigan by the peninsula called Pointe St. Ignace. The shore of Lake Michigan is irregular, but offers no large inlets until Green bay is reached, which opens from the N. W. corner of the lake. More than half of the N. and W. shore of this bay belongs to Michigan, and just within its mouth are two inlets extending northward called the Big and Little bays des Noquets. The general aspect of the northern peninsula is rugged and picturesque. The Porcupine mountains, which form the dividing ridge between the waters of Lake Superior and those of Lake Michigan, are about 2,000 feet high on the W. boundary, and on E., broken here and there by extensive valleys, and throwing off spurs, which in some cases extend to the N. shore. The mountains are succeeded by a succession of plains and hills, which gradually extend into an elevated table-land, and finally into an undulating country, sloping on either hand toward the lakes. The greater portion of this region is occupied by vast forests, and much of the remainder by sandy plains. The northern peninsula contains most of the mineral wealth of the state, but its soil is generally sterile. The southern peninsula is in nearly every respect a contrast to the northern. It lies between Lakes Huron and Michigan, and is bounded on the S. E. by the St. Clair river, Lake St. Clair, Detroit river, and Lake Erie. The Lake Huron shore is broken by Thunder bay toward the N., and Saginaw bay near its centre. There are also several inlets on Lake Michigan, the chief of which are Great and Little Traverse bays. The surface is generally level, although in the S. there is an irregular cluster of conical hills from 30 to 200 feet high. A low watershed, culminating at an elevation of 600 or 700 feet, passes through the country from S. to N., much nearer the E. than the W. shore, with a very gradual and almost unbroken slope toward Lake Michigan, except near Au Sable river, where it partakes of a rugged character. The shores on both sides are in many places steep and elevated, and on Lake Michigan especially there are numerous bluffs and sand hills from 100 to 300 feet in height. The soil of the southern peninsula is luxuri-

antly fertile.—The principal rivers of Michigan are the Ontonagon and Tequamenon, flowing into Lake Superior; the Sheboygan, Thunder Bay, Au Sable, and Saginaw, into Lake Huron; the Raisin, into Lake Erie; and the St. Joseph, Kalamazoo, Grand, Maskegon, and Manistee, into Lake Michigan. Most of these are small, but the streams are so numerous that all parts of the state are abundantly watered. Many small ponds are also scattered over the surface.—The most important mineral resources of Michigan have already been particularly noticed in the articles COAL, COPPER, and IRON. The lower peninsula is composed wholly of groups of the Appalachian series of rocks, the highest of which, the coal formation, occupies the central portion of the country, from which the streams flow on one side into Lake Huron, and on the other into Lake Michigan. Though this is the most elevated portion of the peninsula, the surface is little more than moderately rolling, the strata are horizontal, and the bituminous coal beds lie mostly too low to be worked without raising the water by pumping. The coal field is open to Lake Huron by Saginaw bay, the shores of which are mostly in this formation. It extends as far S. as Jackson, on the line of the Michigan central railroad, where a bed 4 feet thick is opened and worked 90 feet below the surface. From the difficulty of obtaining the coal in large quantities, but little of it is shipped, and even the supplies for the Lake Superior iron works are carried chiefly from eastern Ohio. Around the coal field the underlying carboniferous limestone crops out in a narrow belt, and contains in some localities gypseous shales and some plaster of Paris. To this succeeds the wider outcrop of the slates and sandstones of the Portage and Chemung groups, which stretch along the shores of both Lake Michigan and Lake Huron. The limestones and other strata of the Helderberg and Niagara groups surround these, sweeping around into northern Ohio and Indiana, and eastern Wisconsin, and forming the island of Mackinaw and the point of the peninsula S. of this island. The mineral productions found in these formations are of no great importance. The limestones give fertility to the soil, and are abundantly supplied for all the purposes they can serve. From the shores of Lake Huron, near Thunder bay, an excellent stone is quarried for grindstones; and near Saginaw bay salt water is obtained by boring, and under the bounty of 10 cents per bushel, offered by the legislature in 1859 for the salt thus produced, it is expected that this business will be extensively prosecuted. The northern peninsula of Michigan is for the most part composed of the azoic formations, designated by the Canadian geologists the Laurentian and Huronian; the former comprising the various metamorphic slates and gneiss rocks, and the latter the overlying slates and sandstones, which by many geologists had previously been referred to the lowest of the palæozoic formations. With the lat-

ter are found intercalated masses of trap, and with these the great veins of copper for which the Lake Superior region is particularly distinguished. With the former, the range of which is S. of the copper region, and also to the east of it, are found the immense bodies of magnetic and specular iron ores, an account of which is given in the article IRON. In this and COPPER are contained the statistics of the metallic production of the state, which, of no importance 10 years ago, already gives to Michigan a front rank in this branch of industry among the states of the Union.—The climate of Michigan is one of extremes, but much tempered by the proximity of the lakes. That of the southern peninsula is comparatively mild, while that of the northern, especially in the winter season, is cold and rigorous. The mean annual temperature at Detroit (lat. 42° 20', elevation 580 feet) from 1836 to 1854 was 47.25°; and at Fort Brady (lat. 46° 30', elevation 600 feet) from 1823 to 1854, 40.37°. These results illustrate the isothermal conditions of the two peninsulas, the difference in annual heat being nearly 7° F. The mean distribution of the heat to the seasons in the same years was as follows:

Places.	Spring.	Summer.	Autumn.	Winter.
Detroit.....	45.89°	67.60°	48.67°	26.84°
Fort Brady.....	37.60°	62.01°	43.54°	18.81°

At Detroit the greatest difference in the monthly mean in any one year was 49.97° (21.95° to 71.92°), and at Fort Brady 57.81° (13.19° to 71°). The average annual rain fall at the two places was 30.07 and 31.85 inches respectively, and in the seasons as follows:

Places.	Spring.	Summer.	Autumn.	Winter.
Detroit....	8.57	9.29	7.41	4.86
Fort Brady.....	5.44	9.97	10.76	5.18

It is evident from these facts that the upper portion of the state is beyond the N. line of Indian corn, but here the hardier grains mature. The southern produces Indian corn and the winter grains abundantly, and is the great agricultural district of the state. The soils in this portion are deep, chiefly a dark loam, often mixed with gravel and clay, and very fertile. The northern peninsula with some exceptions is rugged and has a poor soil. It is however well timbered with white pine, spruce, hemlock, birch, oak, aspen, maple, ash, and elm. Much of the southern is occupied by oak openings and prairie, with a large portion of forest, in which walnut, sugar maple, oak, hickory, ash, basswood, elm, linden, locust, dogwood, beech, sycamore, cherry, pine, hemlock, spruce, tamarack, cypress, cedar, and chestnut are the prevailing growths. The principal wild animals of Michigan are the black bear, wolf, lynx, wild cat, panther, fox, marten, weasel, skunk, mink, otter, elk, deer, racoon, squirrel, opossum, marmot, beaver, hare, and rabbit; but these are rapidly disappearing. The lakes and streams afford productive fisheries, among which are those of the far-famed white fish.—Michigan abounds with natural

objects and antiquities interesting to the traveller. Among the former the most noteworthy are the "Pictured Rocks," on the shores of Lake Superior, about 80 m. W. of Sault Ste. Marie. These are sandstone bluffs of various colors, worn by the action of the waters into grotesque forms resembling castles, temples, arches, colonnades, &c., which from a steamer on the lake have the appearance of a gorgeous picture. These rocks extend along the shore for about 12 m., and rise from 200 to 300 feet above the water. Sometimes cascades shoot over the precipice so that a vessel may sail between the descending waters and the natural wall of rock. In the northern peninsula there are the remains of very ancient mines and mining tools, and it is evident that a race well advanced in civilization has occupied the country at some very distant period in the past, and of which the Indians found in possession by the early explorers from Canada could give no account. Foster and Whitney ("Executive Document No. 69," 31st congress, 1st session) give an interesting chapter on this subject.—Michigan is chiefly an agricultural country, but is also engaged to a considerable extent in manufactures, and largely in mining and commerce. In 1850 it contained 84,089 farms, covering 1,924,110 acres of improved and 2,454,780 acres of unimproved lands, valued at \$51,872,446, and the value of implements and machinery thereon was \$2,891,871. In 1854 the amount of land subject to tax was 7,917,322 acres, of which, according to the census of that year, only 2,111,000 acres were under cultivation. The live stock in the state in 1850 consisted of 58,506 horses, 70 asses and mules, 99,676 milch cows, 55,000 working oxen, 119,471 other cattle, 746,403 sheep, and 205,847 swine, in the aggregate valued at \$8,008,734; and the value of animals slaughtered in 1849-'50 was \$1,328,327. In 1854 there were 91,564 horses, 106 asses and mules, 189,260 milch cows, 67,038 working oxen, 141,253 other cattle, 964,833 sheep, and 205,882 swine. The products of animals in the year 1849-'50 were: butter, 7,065,878 lbs.; cheese, 1,011,492; wool, 2,043,283; beeswax and tallow, 359,232; and silk cocoons, 108. In 1854 the quantity of butter was 7,924,896, of cheese 779,580, of wool 2,680,747, and of pork (marketed) 11,258,841 lbs. The grain crops in 1849 consisted of 4,925,889 bushels of wheat, 5,441,420 of Indian corn, 105,871 of rye, 2,866,135 of oats, 75,249 of barley, and 472,917 of buckwheat; in 1853, of 7,027,932 bushels of wheat, 7,680,658 of Indian corn, and 2,294,420 of rye, oats, barley, and buckwheat. The production of potatoes in 1850 was 2,361,074 bushels and in 1853, 2,917,434; hay, 404,934 and 496,041 tons; maple sugar, 2,439,794 and 1,611,463 lbs. The other crops specified in the census of 1850 were: hops, 10,663 lbs.; clover seed 16,299, and other grass seed 9,285 bushels; peas and beans, 74,254 bushels; flax seed, 519 bushels; flax, 7,152 lbs.; molasses, 19,823 galls.; tobacco, 1,245 lbs.; wine, 1,654 galls.; products of mar-

et gardens \$14,728, and of orchards \$182,650. The total value of agricultural products in 1840 was \$3,207,048, and in 1850, \$17,329,385; and the value of home-made manufactures in 1840 was \$113,955, and in 1850, \$340,947. The average crops per acre in 1849 were: wheat 1, Indian corn 32, oats 26, potatoes 140, and rye 14 bushels.—According to the digest of manufacturing statistics published by Congress in 1859, the number of manufacturing, mining, and mechanic establishments in 1850 was 2,028, and the capital invested therein \$5,568,660; the cost of raw material was \$6,36,328; the number of hands employed, 9,844, viz., 8,990 males and 854 females; cost of labor, \$2,716,124; value of products, \$11,169,002. The census of 1850 states the number of establishments at 1,963, and specifies 15 woollen mills (capital \$94,000), 1 pig iron (\$15,000) and 63 cast iron works (\$195,450), 29 distilleries and breweries (\$126,625), and 69 fisheries (\$30,806). The value of manufactures produced in 1810 was \$52,518; in 1820, \$100,460; and in 1840, \$3,899,676. The census of 1854 exhibits the manufacturing statistics thus: flouring mills 45 (24½ steam and 220½ water power), with 18 runs of stones, employing 604 persons and capital of \$1,828,006, and producing (in 1853–4) 998,503 barrels of flour valued at \$3,567,978; saw mills 889 (271 steam and 618 water power), capital \$2,442,577, men 4,579, producing \$3,278,36; oil mills 3, producing 2,203 barrels of oil and 10,782 barrels of peppermint oil; breweries 3, producing 36,392 barrels of beer; distilleries 3, producing 260,840 galls. of spirits, 1,215 galls. of wine, and 2,829½ barrels of cider. The fisheries produced 47,203 barrels. The capital invested in mines was \$4,747,950; and their products were as follows: copper ore, 4,987,881 lbs., valued at \$980,081; iron ore, 1,310,000 lbs., valued at \$32,750; coal, 60 tons, valued at 150.—The foreign commerce of Michigan is chiefly with Canada. Of late years an occasional vessel has been despatched from Detroit direct for Europe, but such occurrences are exceptional. The value of imports and exports for the 10 years from 1850 to 1859 inclusive, ending June 30, was as follows:

Years.	Imports.	Exports.
50	\$144,102	\$182,045
51	183,146	191,426
52	196,240	145,152
53	211,280	253,685
54	204,286	434,495
55	281,879	568,091
56	890,664	981,028
57	1,018,558	1,502,606
58	672,984	5,198,707
59	1,067,889	3,624,624

The shipping employed in this trade in 1858–'9 amounted to 838,419 tons, viz.: entered, 368,30; cleared, 475,089. The shipping owned in the state, June 30, 1859, amounted to 74,371 tons, of which 33,005 tons were steam; and the shipping built amounted to 2,832 tons. Much of the trade is carried on by railroad *via* Sarnia and Windsor, Canada. No estimate of the value

of the domestic trade is attainable; the census of 1854 states the imports (foreign and domestic) entered for sale at \$13,738,122, but this probably included merchandise in transit. The lumber trade is very important, its staple being white pine, which is produced here in great abundance and of excellent quality. Detroit is the principal port engaged in foreign commerce. Monroe, Port Huron, Saginaw, Grand Haven, St. Joseph's, and New Buffalo are chiefly engaged in the domestic trade. The coasting trade is carried on with great activity, chiefly by steamers, and connects the ports of this state with the principal lake ports of the neighboring states, and steam navigation has already been extended to the copper and iron ports of Lake Superior. The total shipping belonging to Michigan and employed in this trade in 1859 was 73,036 tons; but this shows simply the amount and not the movements of the tonnage, and moreover it does not include the shipping registered in other states. The transit trade is carried on chiefly by the three great railroads, the southern, central, and Milwaukee lines, which stretch across the country in an E. and W. direction, having Toledo, O., Monroe, Detroit, and Port Huron as their initial points on the E., and Chicago and Grand Haven (opposite Milwaukee) on the W. These form links in the great chains of railroads between the upper Mississippi on the one hand and the St. Lawrence and Atlantic seaboard on the other; and over these the vast interchange of the commodities of the opposite sections is chiefly effected. The total length of railroads on Jan. 30, 1859, was 1,081 miles; their respective length and cost are given in the following table:

Railroads.	Miles.	Cost.
Detroit and Milwaukee.....	183	\$9,008,869
Detroit, Monroe, and Toledo.....	51	1,202,821
Chicago, Detroit, and Canada G. T. junction.....	57	1,140,000
Iron Mountain (N. Michigan).....	17	850,000
Michigan Central.....	284	12,847,228
Michigan Southern & Northern Indiana (with branches).....	484	14,742,758

A part of this mileage is in other states. There are several lines in course of construction, as those from Port Huron to a junction with the Milwaukee line, from Saginaw City to Lansing and Constantine, from Fort Wayne to Grand Rapids and Mackinaw, from Amboy *via* Lansing to Mackinaw, from Flint to Traverse Bay, &c.; and several in the northern peninsula which will connect with the Wisconsin and Minnesota lines. With these when completed the state will have about 2,500 m. of railroad, and every district will have ample means of communication. The construction of most of these will be aided by congressional land grants. There are several short canals, chiefly harbor improvements, in the state, and others are constructing under the sanction of congress by the topographical engineers. The canal at Sault Ste. Marie, connecting Lakes Superior and Huron, is a most important work,

and though less than a mile in length has been a chief cause of the rapid development of the Lake Superior mining region. The length of post route in this state in 1858 was 7,909 m., of which 880 m. was railroad and 650 m. steam navigation. In Jan. 1860, there were 8 banks in Michigan, whose condition was as follows: Liabilities: capital, \$745,804; circulation, \$147,698; deposits, \$681,748; profits on hand, \$79,287; total, \$1,654,032. Resources: notes, bills of exchange, &c., \$1,487,693; specie, \$41,982; real estate, \$124,357; total, \$1,654,032.—Michigan is governed under the constitution of Aug. 5, 1850. Every white male citizen, and every male Indian not a member of a tribe, 21 years of age, and having resided in the state 8 months and in the district 10 days next preceding an election, is entitled to vote and hold office. The general election is held on the Tuesday after the 1st Monday in November biennially. The legislature (pay of members \$3 a day for 40 days) consists of a senate of 32 members and a house of representatives of 66 members, all elected from districts for 2 years. Sessions begin on the 1st Wednesday in January (odd years) every 2d year. The governor (salary \$1,000) is elected for 2 years by the people at large. He must be 30 years of age, and have been a citizen of the United States for 5 years and of the state for 2 years next preceding. The lieutenant-governor is elected for the same term, and must have the same qualifications. He is *ex officio* president of the senate, during whose sessions he receives \$3 per day. The administrative officers are also elected by the people for 2 years, and have pay as follows: secretary of state, \$800 and fees; deputy secretary of state, \$700; auditor-general, \$1,000; state treasurer, \$1,000; attorney-general, \$800; superintendent of public instruction, \$1,000; commissioner of land office, \$800. The judiciary consists of a supreme court, circuit courts, county probate courts, and justices' courts. Municipal courts are also established in Detroit and other cities. The supreme court consists of a chief and 3 associate justices (salary \$2,500), with a reporter. The circuit court has a judge (salary \$1,500) in each of the 10 circuits into which the lower peninsula is divided. The upper peninsula has a district court, the judge of which receives \$1,000 per annum. All the judges are elected by the people. The public revenue is derived chiefly from taxes on incorporated companies, sales of school and university lands, 5 per cent. of the moneys received for U. S. lands sold within the state, &c. For the year ending Nov. 30, 1858, the total receipts were \$865,720.85; and the total means of the treasury, including a balance of \$158,642.70, amounted to \$1,024,363.05. The disbursements for the same year amounted to \$348,015.85. Nearly one half of the receipts and expenditures are on account of special funds administered by the state. The public debt amounted to \$2,887,629.67, upon which the interest paid the previous year was \$140,257.78. The total value of taxable prop-

erty in the state in 1850 was \$30,877,222, and in 1857 \$120,862,474. The principal institutions supported wholly or in part by the state are the asylum for the insane at Flint, the asylum for the deaf and dumb and the blind at Kalamazoo, the state prison at Jackson, the house of correction for juvenile offenders at Lansing, the state agricultural college, and the state normal school. The whole number of paupers supported in whole or part within the year ending Jan. 1, 1850, was 1,190, at a cost of \$27,556; and the number remaining on the lists was 429. The whole number of criminals convicted in 1849-'50 was 659, and there remained in prison, Jan. 1, 1850, 241.—The school system of Michigan is based upon that of Prussia, the most complete in the world. Ample provision is made for primary schools, and by the grouping of several of these union schools are formed, designed as preparatory to the state university, which is a nearly free institution. On Sept. 25, 1858, there were in the state 3,946 organized school districts, with 225,592 children between the ages of 4 and 18; number attending school, 178,594; average length of schools, 6 months; number of teachers, 7,251 (2,826 males and 4,905 females); paid for teachers' wages, \$442,227. The amount raised by district tax for the support of common schools was \$316,580.71; by a general mill tax, \$116,362.04; by rate bill, \$118,099.59. There were 168,977 volumes in the township libraries, which by act of the legislature in 1854 were authorized to be converted into school district libraries. The principal collegiate and professional schools in the state are the university of Michigan, Ann Arbor; St. Philip's college, Detroit; the medical and law departments of the university; Albion female college and Wesleyan seminary, at Albion; Kalamazoo college at Kalamazoo; and the state normal school at Ypsilanti. The school fund in 1855 amounted to \$1,384,288, and the university fund to \$452,441. The number of churches in the state in 1854 was 399, and the value of church property was estimated at \$723,600. Of the churches, 111 belonged to the Methodists, 72 to the Presbyterians, 66 to the Baptists, 44 to the Roman Catholics, 29 to the Congregationalists, 25 to the Episcopalians, 12 to the Lutherans, 10 to the Dutch Reformed, and 7 each to the Friends and Universalists. In the same year there were in the state 417 libraries, other than private, containing 107,948 volumes. Of these, 260 (65,117 vols.) were public, 119 (31,427 vols.) school (8,500) Sunday school, and 3 (7,900) college libraries. The public press included 58 periodicals, circulating annually an aggregate of 3,247,786 copies, viz.: 3 daily (1,252,000 copies), 2 tri-weekly (52,000), 47 weekly (1,677,786), 3 semi-monthly (184,400), 3 monthly (1,600); and 18 were literary (456,500), 40 medical (2,582,836), 3 religious (184,400), and 1 scientific (74,000).—The word Michigan appears to be derived from the Chippewa language: *mitchaw*, great, and *sagiegan*, lake, a name first

merly applied to both Huron and Michigan, but now restricted to the western lake. The discovery and early settlement of Michigan is due to the French missionaries and fur traders. The site of Detroit was probably visited as early as 1610. Soon after the middle of the 17th century trading posts were established at Sault Ste. Marie, Michilimackinac (old fort), and Green bay. In 1701 an expedition under Antoine de la Motte Cadillac founded Detroit. From this period until the erection of the country into a territory of the United States, there is little in the history of Michigan which demands notice in this place. It made slow progress, and came under the dominion of Great Britain with other French possessions in 1763. On the expulsion of the French the conspiracy headed by the Indian chief Pontiac, and designed for the extermination of the whites, broke out and involved the settlements in bloodshed. The garrison of Michilimackinac was butchered, and Detroit underwent a long siege. On the treaty of peace which closed the revolutionary war, Michigan was not at once surrendered, and the Americans did not take possession of Detroit until 1796. From this time it was included in the government of the territory northwest of the Ohio, and hence has always been amenable to the ordinance of 1787. In 1802, when Ohio was admitted as a state, Michigan was annexed to the territory of Indiana. In 1805 the territory of Michigan was constituted, Gen. William Hull being its first governor. During the war of 1812 it was exposed to great suffering. Detroit was taken by the British in Aug. 1812, under circumstances which led to Gen. Hull, the American commander, being sentenced to death by a court martial; the sentence however was not executed, and facts which have recently come to light relieve his character from the aspersions cast upon it. Michilimackinac was also captured, and at Frenchtown, in Jan. 1813, a number of American prisoners were massacred by the savages. The British were soon afterward driven out of the territory by Gen. Harrison; and in Oct. 1814, a truce was concluded with the Indians. The first land surveys entered upon were commenced in 1816, and in 1818 the lands were brought into market for public sale. From this period the prosperity of Michigan properly dates. In 1818 all the territory lying north of the present states of Illinois and Indiana was annexed to Michigan. In 1819 the territory was authorized by act of congress to send a delegate to that body, and the right of suffrage in this case extended to all taxable citizens. In 1819, 1821, and 1836 the Indians made important territorial cessions, and by this time all the lower peninsula and a part of the upper were freed from Indian title. Up to 1823 the legislative power was intrusted to the governor and judges; but in that year congress passed an act transferring it to a council, consisting of 9 persons selected by the president from 18 chosen by the citizens, and the judicial term was lim-

ited to 4 years. In 1825 the council was increased to 13 members selected as before, but two years later the law was so altered that the electors could choose their councillors without the further intervention of the president or congress. In May, 1835, a convention at Detroit formed a constitution by which Michigan claimed a strip of territory also claimed by Ohio. For a time a conflict seemed inevitable, but in June, 1836, Congress passed an act admitting Michigan into the Union upon condition that she relinquished her claim to the disputed territory, in place of which the region, known as "the upper peninsula," was given to her. These conditions were rejected by one convention, but accepted by another in Dec., 1836, and in Jan., 1837, Michigan was admitted into the Union.

MICHIGAN, LAKE, one of the 5 great lakes of the northern United States, and the only one of them which is entirely included in these states. It lies in a N. and S. direction, extending from the northern part of Illinois 820 m. to Mackinaw, where it communicates with Lake Huron by a strait 4 m. wide in its narrowest part. The lake is bounded on the E. by the lower peninsula of Michigan. The upper peninsula bounds it on the N. W. In this portion is Green bay, which extends S. into Wisconsin; this state and Illinois complete the western boundary of the lake. The following are its dimensions as given by Dr. Douglass Houghton: mean length, 820 m.; mean breadth, 70 m.; mean depth, 1,000 feet; elevation above the sea level, 578 feet; area, 22,400 sq. m., exceeding the area of Lake Huron by 2,000 sq. m. The country around Lake Michigan is for the most part low and sandy; on the E. side particularly the sands thrown up by the waves are blown inland and form hills, which sometimes are 150 feet high. The rocks are the limestones and sandstones of the sub-carboniferous groups, lying in horizontal strata, and never rising into bold cliffs. On the Michigan side they belong chiefly to the Portage and Chemung groups, and on the Illinois side to the Helderberg limestone. Along the southern shores are post-tertiary beds of clay and sand lying a few feet above the level of the lake, and containing fresh water shells like those living in its waters. This fact and the low watershed that separates the lake from the valley of the Illinois river, together with the great capacity of this valley, which appears as if worn by a mighty river, render it probable that the waters of Lake Michigan at some period found their way by the valley of the Mississippi into the gulf of Mexico. The lake at present is believed to be moving westward, gradually encroaching on the shores of Wisconsin and leaving those of Michigan. From observations made at Chicago, Ill., Lieut. Col. James D. Graham, of the topographical engineers, U. S. army, has shown the existence of a lunar tidal wave in Lake Michigan. He published this fact in his report to the war department, Nov. 15, 1858, and also in a communication to the Chicago historical society, on the

30th of the same month. The result of still later observations was given in a memoir read before the American association for the advancement of science at the Newport meeting, Aug. 1, 1860. The mean of 840 observations shows a difference of elevation of the lake surface between high and low water of 153 thousandths of a foot; and the mean of 24 semi-diurnal spring tides (i. e., one day before and two days after new or full moon) gives a difference of elevation of 245 thousandths of a foot, or a little over 3 inches. High water occurs half an hour after the meridian passage, or southing of the moon.— Few harbors and bays are met with around the lake, and the only islands it contains are at its N. E. extremity. It is not therefore a very safe lake to navigate, especially as it is subject to severe storms at different seasons of the year; but until the railroads were completed across the state of Michigan, it was much navigated by fine passenger steamers, whose route extended from Buffalo to Chicago; and many freighting vessels and steamers are still employed during the season of navigation upon the same and many shorter routes. The straits of Mackinaw, which longest retain the ice, are usually open between May 1 and Dec. 1. The fish of the lake are like those found in Lake Huron, and the fisheries are for the most part concentrated about Mackinaw. The best harbors are at Little Traverse bay, and at Grand Haven at the mouth of Grand river on the E. shore of the lake. Chicago, at the head of the lake, has but an indifferent harbor, and the same may be said of those of Milwaukee and Sheboygan on the W. side. There are 23 lighthouses on the shores, beside 4 beacons.

MICHIGAN, UNIVERSITY OF, an institution of learning at Ann Arbor, Washtenaw co., Mich., about 40 m. W. from Detroit. It owes its foundation to a grant of lands to the territory of Michigan made by congress in 1826 to provide for education, and consisting, beside 1,000,000 acres for primary schools, of two townships containing 72 entire sections, which, on the admission of Michigan into the Union in 1836, were conveyed to the state solely for the use and support of the university. The plan of the university originated with the Hon. J. E. Crary and the Hon. John D. Pierce. It was at first grafted upon the college of Detroit, and the present institution was established by an act of the legislature in 1837. No portion of the 72 sections of land had been sold, except to the amount of \$5,000 by the trustees of the old university; and as no funds existed with which to put the institution in operation, \$100,000 was borrowed in 1838, for which the state gave its bonds payable in 20 years. This was lent again by the state to the university, with the agreement that the principal and interest were to be paid out of the income of the university lands. About \$122,000 has been paid in interest and discount on this loan, and it still remains a debt from the university to the state; but the legislature has remitted the interest until further

legislation. In 1842 the faculty consisted of 4 professors. In 1843 there were 50 students; and the first class, numbering 11, was graduated in 1845. The medical department was organized with 80 students in 1850, and the law department with 90 students in 1859. Before 1850 the institution had never had a president or a distinctive officer. A new board of regents chosen by the people, in accordance with a change in the constitution effected in 1850, elected the Rev. Henry P. Tappan, D. D., of New York, with the title of chancellor. One of his earliest achievements at the university of Michigan was the establishment of a first class astronomical observatory, the subject of which was first introduced in his inaugural address in 1852. The funds arose from a subscription by the citizens of Detroit, and in 1854 Dr. Brtton was invited from Berlin to take the direction of it. In 1856 a chemical laboratory was erected. In the same year an important addition was made to the natural history collection through the instrumentality of Prof. Trumbull of the university, formerly of the corps of engineers of the army, consisting of 300 specimens in zoology, duplicates of collections made by him on the Pacific coast for the Smithsonian institution. At the same period Prof. Fiske brought from Europe valuable additions of books, maps, engravings, photographs, and copies in plaster and terra cotta of some of the most beautiful antiques of the great museums of Naples, of the Vatican, and the Louvre; and Prof. Bradish was subsequently sent abroad by a faculty of the university to make an extensive collection of similar copies. The medical and general scientific collections are valuable. There are now (1860) 28 professors and instructors and over 600 students, 120 of whom are law students, and the clear income of the institution is about \$40,000 per annum. The only charges to students are an admission fee of \$10 and an annual payment of \$5.

MICHIGAN CITY, a village of Laporte co., Ind., on the S. shore of Lake Michigan, at the mouth of Trail creek, 13½ m. N. W. from Laporte, and 56 m. S. E. from Chicago; pop. in 1850, 2,858; in 1860 estimated at 3,500. It is the principal lake port in the state, and has excellent facilities for trade. The Michigan central, and the Louisville, New Albany, and Chicago railroads intersect at this point. It contains 7 churches (5 Protestant and 2 Roman Catholic), a number of manufactories and warehouses, several benevolent institutions, and a weekly newspaper office.

MICHILIMACKINAC, or **MACKINAC**, an E. co. of the upper peninsula of Michigan, bordering on Lake Michigan and the straits of Mackinaw; area, 1,800 sq. m.; pop. in 1850, 3,100. The surface is uneven and is well wooded. Timber is the principal article of export. In 1850 there were 10 churches, and 848 pupils attending public schools. Capital, Mackinac.

MICHILIMACKINAC, **MACKINAC**, or **MACKINAW**, the capital of Michilimackinac co.

Mich., on an island of the same name in Lake Huron, 820 m. N. N. W. from Detroit; pop. about 1,500. It has a safe and deep harbor, and is a fashionable summer resort. Fort Mackinac, a U. S. military post, is on a rocky eminence about 150 feet high commanding the village. It contains the county buildings, several churches, 2 saw mills, 8 stores, and 4 hotels. It exports considerable quantities of fish.

MICHOCAN, MECHOCAN, or VALLADOLID, a state of the Mexican confederation, bounded S. W. by the Pacific, and on other sides by Colima, Jalisco, Guanajuato, Queretaro, and Mexico, between lat. 17° 55' and 20° 87' N., and long. 100° and 104° W.; area, 22,220 sq. m.; pop. 491,679. The state is divided into 4 departments and 62 municipalities. The N. and E. consists of a table land 5,000 to 6,000 feet above the level of the sea, from which rise several snow-covered peaks. Toward the W. the country descends by terraces to the Pacific, along which stretches a tract of low land extending several miles inland. There are numerous small streams, but the Bolsas, which forms the boundary toward Mexico on the S. E., and the Lerma, with their respective tributaries, are the most considerable rivers. There are several lakes in Michoacan. A great deal of the soil is fertile and capable of producing all the ordinary fruits of the temperate and tropical regions. The sides of the mountains are covered with valuable timber. There are mines of gold, silver, and lead, which were once wrought extensively. As there are no seaports on the coast, the productions of the state are carried inland to Mexico and other places. Morelia, or Valladolid, is the capital, and the other principal towns are Páscaro and Zitacuaro. The climate is remarkably healthful. Along with Jalisco and Colima, this state formed the ancient kingdom of Michoacan.

MICKIEWIOZ, ADAM, a Polish poet, born in Novogrodek, Lithuania, in 1798, died in Constantinople, Nov. 27, 1855. He was the son of a poor advocate of noble birth, and studied at his native place, at Minsk, and at the university of Wilna, where he became intimately connected with the historian Lelewel, and with the patriot Zan. Having for some time studied physics and chemistry under Sniadecki, Mickiewicz finally devoted himself almost exclusively to literature and poetry, and received an appointment as professor of literature at Kovno. In 1822 he published in Wilna two small volumes of poetry, which contained, among others, some of the finest ballads in the Polish language, a historical epic, "Grażyna," the scene of which is his native place, and the principal character a Lithuanian heroine, and under the title of *Dziady* a romantic autobiographical drama, in which the author described his unhappy love for Maria, the sister of a former fellow student. This collection, which was afterward augmented, and of which "Grażyna" is undoubtedly the most valuable part, at once raised Mickiewicz to the highest rank in Polish poetry. He was idolized by the revolutionary youth of Poland, par-

ticularly after he was tried for participation in the secret associations of Zan, imprisoned in the Basilian convent at Wilna, and finally condemned, in 1824, to perpetual banishment from his native country. He was removed to St. Petersburg, where he became familiar with the most distinguished Russian liberals, and subsequently to Odessa, whence he was allowed to make a tour through the Crimea. This he partly described in his "Sonnets," which were soon after followed by his second epic, "Wallenrod," published in 1828 at St. Petersburg, whither he had received permission to return. This poem, in many respects one of his greatest productions, the theme of which is the struggles of the Lithuanians in the 14th century against their oppressors, the Teutonic knights, though breathing throughout the spirit of the most unbridled hatred of foreign dominion, was favorably received in Russia, being also translated into the Russian language, and the author was even allowed to enter upon a tour through Germany and France to Italy for the restoration of his health. At Rome, where he made the acquaintance of J. Fenimore Cooper, he received the news of the outbreak of Nov. 29, 1830, in Poland. Mickiewicz, however, did not reach the confines of his native country until the great struggle had ended in a terrible catastrophe, and he never more entered Poland; but as an exile in foreign lands, he could now give full vent to the domineering passion which animated his glowing poetry. He went to Dresden, and there wrote the 2d part of *Dziady* (Paris, 1832), in which he described his imprisonment and the cruelties perpetrated by Russian tyranny on Poland, in verses full of the wildest romantic eccentricity, and bristling with horrors of every description. A little less extravagant production, but one also of less merit, was his *Księgi narodu polskiego i pielgrzymstwa polskiego* ("Books of the Polish Nation and the Polish Pilgrimage," Paris, 1832), which was followed by another of his great poetical works, *Pan Tadeusz* ("Sir Thaddeus," Paris, 1834), a picture of Lithuanian life and society in 1812 at the approach of Napoleon's invasion, which is the chastest, and, according to the judgment of many, the noblest of his writings. In the same year, having now established himself at Paris, he married Celina Szymanowska, a Polish lady, who had been an early acquaintance. In 1839 he accepted a professorship of classical literature at Lausanne in Switzerland, but in the following year he returned to Paris to fill the chair of Slavic literature recently established at the collège de France. His spiritual life had long before undergone a striking metamorphosis, and he was already known as a zealous if not fantastic advocate of Roman Catholicism, from which he hoped for a regeneration of his country, as well as of Panslavic tendencies, which were not shared by all of his fellow exiles. His "Lectures on Slavic Literature," published in both French and German, gradually developed still more surprising phases. The inspiring genius of these

revelations was a fanatical Polish priest, Towianski, who had mesmerized Mme. Mickiewicz in a dangerous illness in 1841, from which she recovered, and who, pretending to be enlightened by celestial visions, was followed by Mickiewicz as the Messiah of a new religion, in which the memory of Napoleon received almost divine honors. The reputation of Mickiewicz had greatly decreased with these developments, which caused the expulsion of Towianski from Paris, and the interruption of the lectures by the government, when the revolution of Feb. 1848, inspired the poet to new activity. In order to gain over Pius IX. to his schemes of national regeneration, he started for Italy, and at Florence received a flattering ovation. In 1851 he was appointed by Louis Napoleon, then president, sub-librarian of the library of the arsenal at Paris; and on the outbreak of the war against Russia, he headed a Polish deputation to the French emperor, calling upon him to turn the great movement in favor of their oppressed country. Soon after he was sent on a secret mission to Constantinople, where he ended his career. His wife having died before him, a subscription was raised for the benefit of his children in France and England. His remains were removed to the cemetery of Montmartre, Paris, where they rest between those of his distinguished countrymen Niemcewicz and Kniaziewicz. His works have passed through numerous editions, and have been partly made known to other nations in various more or less successful translations.

MICKLE, WILLIAM JULIUS, a Scottish poet, born in Langholm, Dumfriesshire, in 1784, died in Wheatley, Oxfordshire, Oct. 25, 1788. After pursuing various occupations, he became in 1765 corrector of the Clarendon press at Oxford, and from time to time he produced small poems which gained him some notice. In 1771 he published his translation of the 1st book of the "Lusiad," and completed the work in 1775, since which time it has passed through many editions. "Oumnor Hall," the best perhaps of all his poems, suggested "Kenilworth" to Scott.

MICROMETER (Gr. *μικρος*, small, and *μετρον*, measure), a contrivance adapted to the telescope and microscope for measuring minute spaces, angular or linear, in the field of view. It is not a little remarkable that the simplest micrometer now in common use (Troughton's filar) does not greatly differ in its most essential principle from the network of silver wires constructed about 1622 by the marquis of Malvaria, and is almost identical in its leading features with the instrument devised by Gascoigne in England about 1640, as improved soon after by his countryman Dr. Hooke. This instrument, called variously the parallel wire, the wire, the spider line, and the filar micrometer, consists essentially of a pair of parallel fibres—a spider's web usually—with a contrivance for separating or bringing them into coincidence, together with an arrangement for denoting the distance between them at any degree of separation. This motion is given by very fine-threaded

screws working against frames across which the fibres, or wires, as they are called, are stretched. Placed in the focus of the instrument, it affords a means of subdividing minutely the field of view, and of accurately measuring the interspaces; so that the apparent diameter of a body, a planet for example, or the apparent distance apart of two stars or other bodies lying in the same field of view, can be determined. The number of turns and parts of a turn of one of the screws necessary to move the wires across the interval to be measured, expresses the measurement. A motion given to this apparatus in a plane perpendicular to the axis of the instrument constitutes it a position micrometer, the use of which is to determine the difference of direction between a fixed line, a parallel of declination for example, and a line joining two points in the same field. There are many modifications of the filar micrometer, in which the wires are fixed in position, and in one of which the interspaces are widened or narrowed optically by changing the magnifying power of the instrument. This is done by varying either the distance of the two parts of the eye piece or the focal length of the object glass by means of another object glass interposed. Instead of using the web of the spider, lines are sometimes cut on glass with fluoric acid. One great drawback in the use of the filar micrometer is its incapacity to measure any except very minute distances. Mr. Alvan Clark, of Boston, has invented a modification of the instrument, which enables him to measure any distance up to one degree. The best and most expensive micrometers are constructed on the principle of the duplication of the image according to optical laws. This is accomplished in the heliometer by dividing the object glass of the telescope along a plane passing through the optical axis of the instrument; each half will form a perfect image, and the two images are separated or brought into coincidence by a sliding motion of the prisms in their common plane and in the direction of their cut edges. In another variety of the instrument the double images are separated optically. Two prisms, producing independent images, are fixed together and arranged to move between the object glass and its principal focus, thus varying at pleasure the angle which the images form. The property which some crystals, as Iceland spar, possess, of causing bodies viewed through them to appear double, is also applied to the construction of micrometers. Lewis M. Rutherfurd, Esq., has in use at his private observatory in New York an ingenious and convenient micrometer in which a double image is produced by the use of two parallel plates of glass placed edge to edge in the eye piece of the telescope. The angle of the images is varied from zero by giving to one plate a revolving motion around an axis contained in the common plane of the two, and perpendicular to their line of section, while the other plate remains fixed.

MICRONESIA AND MELANESIA (Gr. *μικρος*, small, *μελας*, black, and *νησος*, island), terms derived from the size and complexion of the inhabitants, and applied by some geographers to arbitrary divisions of the islands of the Pacific ocean. These divisions are both comprehended in the better defined, more convenient, and better understood terms of Australasia and Polynesia. Micronesia and Melanesia occupy the western portion of the Pacific. The former extends from the westernmost island of the Sandwich group to near Japan and the Philippines, and reaches S. of the equator, comprehending the Ladrone islands, the Carolinas, and the Pellew islands. Melanesia embraces the Feejee islands, the New Hebrides, Solomon's islands, New Caledonia, New Britain, New Ireland, and New Guinea.

MICROSCOPE (Gr. *μικρος*, small, and *σκοπεω*, to see), an optical instrument used for the examination of minute objects. Microscopes are of two kinds, simple and compound. With the former, the object is viewed directly, either by means of a single lens or a set of lenses employed in the same manner as a single lens. With the latter, an enlarged image of the object is formed, by a single lens or a set of lenses, termed the object glass or objective; this image is viewed and further amplified by means of an eye piece or "ocular." Each form is valuable in its place, but as a general instrument of research the compound form, with all the modern improvements, is greatly superior. The invention of the simple microscope is not claimed by any one, but that of the compound has been warmly disputed; it is claimed by the Italians and the Dutch. The compound microscope of the present day, however, is a very different instrument from the disputed invention, and it is to this last and best form that we propose to devote the most of our attention.—The earliest magnifying lens known, if indeed it was used for this purpose, is the rude one found by Mr. Layard in the palace of Nimroud; it was made of rock crystal, and was far from perfect. Seneca (*Nat. Quæst.*, lib. i. cap. vi.) alludes to the magnifying power of a glass globe filled with water; he ascribes the effect to the water, and appears to refer to objects immersed in the water; this was about the middle of the first century. "Burning spheres," as they are termed by Aristophanes, were sold in the shops of Athens in the days of that comic author. There is no evidence that lenses at this early date were employed for magnifying, at least further than for reading glasses. It is not until the 17th century that we find powerful magnifiers of glass actually employed for scientific investigation. The names of Malpighi, Lieberkuhn, Hooke, Leeuwenhoeck, Swammerdam, Lyonnnet, and Ellis are closely connected with the history of the simple microscope; and the important discoveries made by them sufficiently attest the value of even this form of the instrument. Most of the magnifiers employed by the early observers were minute single lenses of

glass; often small spheres formed by melting threads of glass in the flame of a spirit lamp. The form usually given to the small single lenses of high power is plano-convex, the plane side toward the object; when carefully made, having a focal length of from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch, and well set in shallow blackened cells, with the proper aperture, they perform on ordinary objects tolerably well; much better than the minute glass spheres, as the latter are difficult to obtain free from bubbles. The writer has succeeded better by melting a fragment of plate glass in a small hole in a German silver cup, by means of the blowpipe, and has formed lenses in this way, ready mounted for use, quite equal to those ground and polished by hand. The German silver is blackened by the heat. In order to diminish the spherical aberration in the high magnifier of a single refracting substance, Sir David Brewster suggested the employment of gems; and Mr. Pritchard of London, under the patronage of Dr. Goring, succeeded in grinding lenses of garnet, sapphire, and diamond, all of which proved superior to glass lenses of equivalent focus. The diamond lenses upon the whole were inferior to the sapphire; the latter, though not as highly refractive, were free from the veins which rendered several of the diamond lenses useless, though still affected, in common with the diamond, by double refraction. The garnet lenses are free from this latter defect, and when very minute are much superior to glass; the color is not objectionable when the lenses are very small. All the magnifiers composed of single lenses, glass or gems, are surpassed by the doublets and triplets. The invention of the doublet in its best form is due to Dr. Wollaston; it appears, however, to have been a chance discovery. It consists of two plano-convex lenses, having their plane sides toward the object; the posterior lens (that nearest the eye) is three times the focal length of the anterior, and the distance between them is twice the focal length of the shorter. It is evident that the front lens of the doublet must be approached much nearer to the object than if it had been used alone, and the amplification is also less than that of the front lens alone; hence the working distance is much less than that of an equivalent single lens, and not greater, as erroneously stated by some authors. The great and surpassing advantage of the doublet is the enlarged angular aperture, and diminution of spherical aberration. By "angle of aperture" is meant the angular breadth of the cone of rays proceeding from the object, and, after impinging upon the lens or set of lenses, refracted through. Evidently, with a single lens, having an aperture equal to its focal length, the angle will be about 55° ; in other words, the lines drawn in the same plane from a point to the margin of the lens, this point being in the axis of the lens, and at a distance from its convex surface equal to the diameter of the lens, will be 55° ; no single lens, however, will admit any thing like this aperture. Now in the

doublet the front lens is approximated much closer to the object than it possibly could be if employed alone, and hence it admits a wider angle; the reduction of magnifying power, at the same time, diminishes spherical aberration, which is still further reduced by the peculiar relations of the curvatures. The doublet thus becomes a very superior instrument, and, when well made and carefully used, surpasses all but the most improved forms of the compound instrument. Doublets of gems are far superior to those of glass. Many years since the writer made several garnet doublets of $\frac{1}{4}$ to $\frac{1}{8}$ of an inch focal length, which in performance on test objects quite equalled the best French achromatics of the day. Triplets are superior to the doublets; and for a simple microscope the achromatic triplets now furnished by the French and German opticians, as objectives for the compound microscope, will be found very effective. Essentially, the English and American achromatic objectives are triplets, but the peculiar mounting of these instruments prevents their use as simple microscopes. So great has been the improvement, that the best modern objectives will transmit angular pencils of 170° to 178° . We may notice here the so called "Coddington lens," or grooved sphere. It is an invention of Sir David Brewster, and when properly made is almost free from spherical aberration, and the chromatic aberration is almost insensible. "It consists of a spherical lens, or sphere with a deep concave groove cut round it, so as to cut off the marginal pencils, and thus give a wider field and more perfect image." The lenses usually sold under this name are simply cylinders of glass having spherical ends, and of course have none of the advantages of large field and freedom from spherical aberration proposed by Dr. Brewster. When the curvatures of this cylindrical lens are unequal, and such that, the most convex being turned toward the eye, an object placed on the other convex surface is in the proper focus of the lens, it is called a "Stanhope lens;" its use is limited to such objects as can be directly applied to the surface. When of considerable power it may be advantageously employed in searching for *diatomaceæ*; the drop of water supposed to contain them may be examined by applying it to the least convex surface. All the simple microscopes, and especially the higher powers, require some kind of a stand or carrier. The lower powers and single lenses are usually attached to the end of a jointed rod, which can be moved up and down a stem inserted into a solid base. The most convenient mounting for a 1-inch or $\frac{1}{2}$ -inch lens for the purpose of preliminary examinations, or botanical dissections, is that of Messrs. Powell and Leland of London, and is employed by them as the mounting of the small condenser for their compound instrument. The movements are complete, and one can place the lens, whatever may be the position of the object, in such a relation to it as will insure the best view. For the higher powers, $\frac{1}{2}$ to $\frac{1}{8}$ of an inch, a steady

well made stand will be required, and some means of adjusting the focus delicately, either by rack-work or screw. Various forms have been devised by different opticians; perhaps upon the whole, that known as the "Ramsden" is most simple, and at the same time of great excellence. It consists of a brass pillar, up and down which a large circular stage is moved by rack-work; a large mirror, one side plane the other concave, swings freely below, and serves to direct the light upon the object; at the top of the brass pillar is placed the lens holder, movable forward by means of a screw and laterally by swinging round a pin inserted in the top of the pillar; into the opening of the stage is fitted a glass plate, or it may be used to hold dissecting troughs with glass bottoms. It is often convenient, or absolutely necessary for the examination and dissection of opaque objects, to have the lens inserted in a silver cup, or Lieberkuhn, which, receiving the light from the mirror below, reflects it back, condensed, upon the object. These Lieberkuhns are usually made of silver. The very simple microscope employed by Ellis in his researches on corallites, and in which all the adjustments were effected by sliding by the hand, was fitted with these silver cups. Although the Lieberkuhn is very commonly applied to the low power achromatic objectives, it is now seldom to be obtained in any form of simple instrument, unless by special order; it will be found of the greatest service in minute dissection. In using lenses of moderate foci, $\frac{1}{2}$ to $\frac{1}{4}$ inch, the most extended distinct vision is obtained when the convex side is presented to the object; but the sharpest vision of a minute point or small object, in the centre of the field, is when the flat side is presented to the object. In estimating the magnifying power of such lenses, an arbitrary standard of the nearest distance at which the healthy unassisted eye can view distinctly minute objects is assumed, this distance has been placed at from 5 to 10 inches. The latter is the standard adopted by most opticians and authors; Sir David Brewster actually adopts 5 inches. The magnifying power is usually expressed lineally, or as "so many diameters." Thus, when the magnifying power is stated to be 40, it is meant that the diameter is increased 40 times, but of course the area will be increased 1,600 times. The following table exhibits the linear and superficial magnifying power, adopting the standard of 10 inches.

Focal length in inches.	Linear magnifying power.	Superficial magnifying power.
2	5	25
$1\frac{1}{2}$	6.6	43.5
1	10	100
$\frac{3}{4}$	13.3	176.4
$\frac{1}{2}$	20	400
$\frac{3}{8}$	40	1,600
$\frac{1}{4}$	80	6,400
$\frac{1}{8}$	160	25,600
$\frac{1}{16}$	320	102,400

As it is difficult to measure exactly the focal length of small lenses, a sufficient approximation may be had by the method proposed by Mr. Ross, which answers admirably for dissection.

and triplets. It consists in "viewing the image of some distant object formed by the lens in question, through another lens of one inch solar focal length, keeping both eyes open, and comparing the image presented through the two lenses with that of the naked eye. The proportion between the two images so seen will be the focal length required. The panes of glass in a window, or courses of bricks in a wall, are convenient objects for this purpose." The comparative focal lengths of two lenses, or sets of lenses, may be determined by holding them at the same distance from the eye and estimating the sizes of the images formed by each of the same object; thus, if one lens forms the image half the size of the other, lineal measure, its focal length is half that of the other. The same method applies to eye pieces.—We pass now to the compound microscope, and shall dwell only upon the construction and use of the instrument in its most approved form. For a history of the earlier forms, the reader may consult the elaborate works of Quekett and Harting, and the older works of Adams and Baker. Essentially it consists of two parts, the object glass and the eye piece. The former is now made by a combination, usually, of 3 sets of achromatic doublets, arranged to give the greatest freedom from spherical and chromatic aberration; the latter, of two plano-convex lenses, with the plane sides to the eye, the lens nearest the object, or "field lens," being almost exactly double the focal length of the eye lens, and the distance between them a little more than the focal length of the field lens; the ratio is varied somewhat by different makers. The eye piece thus formed is termed a "negative eye piece," or the "Huyghenean." The eye piece of Kellner is a decided improvement; it is termed "orthoscopic," and the eye lens is achromatic or nearly so; these eye pieces are supplied by the Messrs. Grunow of New Haven, Conn., with their best instruments; the field of view is large, free from distortion, and well defined throughout the whole extent. The orthoscopic eye piece supplied by Mr. Charles A. Spencer, and more recently as improved by R. B. Tolles, of Canastota, has both eye and field lens achromatic, and is exceedingly perfect; it is, however, more expensive than the Kellner eye piece. Mr. Tolles has also introduced very recently a solid, orthoscopic, negative eye piece, of remarkable clearness and definition throughout, especially fitted for micrometric use, the engraved scale being cemented in the body of the solid eye piece, and perfectly protected from all dust or interference with definition, so noticeable in the use of the eye-piece micrometer in the ordinary way. So far as we are aware, the English opticians have not yet adopted the improved eye pieces, but have devoted all their skill to the perfection of the objectives and the stands. The "Jurors' Report" of the exhibition of 1851 mentions a solid eye piece, a positive triple achromatic, very thick; but it appears not to have come into general use. Mr. Tolles has also

introduced what is termed an amplifier, being an achromatic concave of peculiar construction, which is introduced within the body of the microscope by means of an adapter. The corrections of the objective are not in the least disturbed by this arrangement, but the power is doubled. A low eye piece thus gives as much amplification as a higher one, but with the very great advantage of almost perfect flatness of field.—The object glasses, or "objectives" as they are now very commonly termed, derive their denominations, 1 inch, $\frac{1}{2}$ inch, $\frac{1}{4}$ inch, &c., from the fact that the combined sets of lenses give a magnifying power the same as a single lens of the same name. Thus, a $\frac{1}{4}$ object glass should give the same amplification as though a single lens of $\frac{1}{4}$ of an inch was used in its place. This term does not refer at all to the working distance, for, as is the case with doublets, the working distance with all powers higher than the $\frac{3}{4}$ inch is considerably less than that of the equivalent single lens; it will be apparent that for any given focus the working distance will, in general, be diminished by an increased angle of aperture; a $\frac{1}{4}$ of 90° will have in this respect a very great advantage over a $\frac{1}{4}$ of 140° . As regards the merits of the large angle objectives, there are various opinions. Dr. Carpenter is decided in his condemnation, considering that depth of penetration cannot be had at the same time with enlarged angle. The skill of the first opticians, Spencer, Tolles, and Grunow in America, Ross, Powell and Leland, and Smith, Beck, and Beck in England, have proved the contrary. Nor is Sir David Brewster's assertion true of large angle objectives, that they give a distorted view. The definition, clearness, and perfectness of vision with Powell and Leland's $\frac{1}{8}$, having an angle of 176° , when employed with a low eye piece so as to give the same amplification as a $\frac{1}{4}$ with a higher, is greatly superior to that of the $\frac{1}{4}$. The chief advantage of the small angle has been considered to be the sort of general view it would give of the whole of a minute object; the working distance being so great, that the minute elevations and depressions in the object itself, being but a very small fraction of the whole distance, would not perceptibly affect the focus. In many respects, this might be a desirable quality; but we are convinced that the microscopist would quite as often find it a source of error in his interpretation of what he might observe. We feel fully assured, that in minute and elaborate investigations the high angle objectives are the most trustworthy. Moreover, the skill of the opticians named has enabled them to increase the angle without diminishing so very much the working distance. The $\frac{1}{4}$ of Mr. Ross, of recent make, and we believe the $\frac{1}{8}$ of that of Powell and Leland, will work through glass .01 ($\frac{1}{100}$) of an inch in thickness.—In speaking of the objectives of the prominent makers, we do not desire to indicate any order of precedence; they are all excellent, and all have peculiarities of their own. We must, however,

be permitted to notice a little more fully the American artists. The oldest optician, and the one who has been most known in connection with the microscope in the United States, is Mr. Charles A. Spencer of Canastota, N. Y. The object glasses furnished by this gentleman, particularly the later ones, are of the highest order; they range from 8 inch to $\frac{1}{8}$ inch. By many of our most experienced microscopists they are considered superior to the best objectives of the London opticians; they are certainly equal to them. Mr. Spencer, in the earlier days of high angle objectives, no doubt surpassed in this respect all the English opticians; his rare skill and nice manipulation enabled him to perform wonderful feats in this direction, far in advance of any thing before accomplished. Mr. Robert B. Tolles, for some time connected with Spencer, but now by himself at Canastota, has devoted himself to the perfection of the achromatic objectives with enthusiastic zeal and unparalleled success. His recent objectives are quite equal in defining and penetrating power to the very best of the London opticians, both with central and oblique illumination, and greatly superior to them in the latter case, as regards chromatic aberration; this is true also of Mr. Spencer's objectives. Mr. Tolles's objectives range from 8 inch to $\frac{1}{8}$ inch. Messrs. J. and W. Grunow of New Haven, Conn. (the former now of New York) have sent out some very fine objectives, ranging from 2 inch to $\frac{1}{8}$ inch. They have not attempted generally so high angles as Spencer and Tolles, but have devoted great attention to the mechanical arrangement and efficiency of their stands, and the accessory apparatus. In this department especially they are unrivalled, and they alone, of the American opticians, have adopted Mr. Wenham's superior mode of adjustment of the high power objectives for thickness of cover.—Of English opticians, the name of Andrew Ross has always been placed foremost, being connected with the greatest improvement of the objective, without which the higher powers of large angle would be almost valueless; we allude to the adjustment for cover. First of all the opticians Mr. Ross made his objectives so perfectly corrected for spherical and chromatic aberration, that a new source of difficulty, apparently almost insurmountable, presented itself. He found that these aberrations, so nicely balanced, were disturbed by each varying thickness of the thin covering glass over the object. The happy expedient he devised to remedy this, was to alter the distance between the first set and the two posterior sets of achromatics composing the objective, by means of a delicate screw collar. This grand and capital improvement, for which Mr. Ross deserves the rank assigned him, has been adopted by all the American and English opticians, and more recently by the French and German. The English uniformly, if we except the amateur efforts of Mr. Wenham, make the front set movable; the American opticians move the two

posterior sets, the front being immovable; the latter method is better, the object being kept easier in view during the adjustment, and there being no danger of bringing the front lens in contact with the object. The objectives of Mr. Ross have always maintained a high character, and have been more expensive than those of Powell and Leland, or Smith, Beck, and Beck, though they probably do not surpass them. The business is now conducted by Mr. Thomas Ross, the son of A. Ross, who has lately died. Mr. Ross's objectives range from 8 inch to $\frac{1}{8}$ inch. Messrs. Powell and Leland, so far at least as the objectives and accessories are concerned, are quite equal if not superior to any living opticians. Both the low and high powers of this firm are of the finest character. While the general plan is the same, there are some peculiarities in their high power objectives worthy of notice. The front set is triple, and the front lens being of crown glass is less liable to injury from wiping, or accidental contact with the object, than the soft flint of other opticians; but as it is a very thin plano-convex, merely cemented to the concave, and not burnished in, it is liable to injury by parting the cement. Messrs. Smith, Beck, and Beck are more widely known in this country than the other firms. Their "students'" and "educational microscope" are the forms usually sold by the dealers. As opticians, they stand side by side with the others named; as mechanics, in some respects, they appear to be in advance. They do not furnish objectives higher than $\frac{1}{4}$ of 125° angle. We have space only to mention the names of Nachet, Oberhauser, and Kellner, whose objectives are excellent, but inferior to the American or English; they are, however, much cheaper, and the mechanical work upon their instruments is very excellent. The name of Prof. Amici of Modena has long been associated with the microscope. The objectives made by him consist of 6 series, with angles varying from 26° to 160°; the higher powers have no adjustment for cover, but the front lens is made slightly concave, and a drop of water introduced between the cover and the objective, thus in a measure rendering the adjustment unnecessary. This contrivance is ingenious but awkward, and is a poor substitute for that suggested by Mr. Ross. Finally, we must not omit to name Mr. Lister, who first pointed out some peculiarities possessed by a combination of 8 achromatics with their plane sides toward the object, the crown and flint being cemented together, and which were the basis of subsequent improvements. The peculiar form adopted by Lister has long since been abandoned, the principles, however, being the same.—The stands furnished by the principal makers exhibit a great variety of patterns, and combine various excellences. The most desirable points, viz., freedom from tremor, ease of illumination, particularly oblique illumination, facility in the application of the accessory apparatus, and delicacy of adjustment, are nearly

equal in the first class stands of the principal opticians; but perhaps, upon the whole, the best are those of Messrs. Smith, Beck, and Beck. Their large stand mounted on two pillars is remarkably steady. The stage, thin but substantial, is large, and its movements are very smooth and delicate. The illuminating and accessory apparatus is carried by a sub-stage below, and most easily applied. The illuminating mirror is large, and so mounted as to give very oblique illumination. The rack-work of the quick adjustment is always of the smoothest and best character in all of the instruments made by this firm, and the slow adjustment very delicate. The greatest fault in this stand is the attachment of the slow movement at the lower part of the tube of the microscope itself. In this respect, the stands of Ross, Powell and Leland, Spencer, Tolles, and the Messrs. Grunow, are superior. With the high powers, the springing of the tube when the finger is applied, and the shaking when the adjustment for cover is attempted, are disagreeable. The larger students' microscope made by this firm is a very fine instrument; the stage movements and adjustments are very complete. The stands furnished by Ross are too heavy and cumbersome; they are, however, exceedingly steady, and finished with extreme care. Those supplied by Powell and Leland are much lighter, and have some peculiar advantages. The accessories supplied by this firm are more complete than those of any other; the stage of their new and largest instrument is very thin, and allows greater obliquity of illumination than that of Smith, Beck, and Beck. Their achromatic condenser is beautifully finished; it has an angle of 170° . The stand itself is not as steady as that of Smith, Beck, and Beck, but the fine adjustment is more conveniently placed. The stands furnished by Messrs. Grunow are of different patterns, but all excellent in beauty of finish, smoothness of adjustment, and steadiness, comparing most favorably with the English work. The stands furnished at Canastota by Spencer and Tolles have many excellences, and are very steady. Their more recent stands evince a most decided improvement in general finish and in the accessories, and we doubt not that the American stands will soon, as already do the American objectives, to say the very least, fully equal the best English work.—All good instruments should have a graduated draw-tube within the main tube, and the latter should be not less than 1.4 inch in diameter. As a general rule, the American microscopes have had too small and short bodies, so that they have appeared, by the side of the English instruments, little and inferior. The draw-tube is absolutely necessary for micrometry, and is very convenient to receive the analyzing prism, erector, or Tolles's amplifier. Two adjustments for focus are also necessary, one quick by rack-work and pinion, the other very delicate by screw. The pinion heads should be large, to allow of most delicate movement, and Messrs.

Smith, Beck, and Beck graduate the head of the screw of the fine adjustment, so that the thickness of covering glass may be measured. A skilful observer may dispense with the rack movement, and produce the approximate adjustment by sliding the tube. This is the method adopted in most of the French instruments, and in the "educational" of Smith, Beck, and Beck. The stage movements should be smooth, and but slightly disturb the adjustment when in focus. The adjustment for wear in the English instruments is by spring, in the American by screws; the former involves more work for the maker, but is better. The lever stage, though performing finely when first from the hands of the maker, is much more liable to derangement than that in which the motions are produced by rack and screw. In the Smith, Beck, and Beck instruments the rack and screw are both so low that the latter passes entirely under the bottom of the stage, which is consequently much thinner than it can be made when the screw is introduced between the movable plates, as is the case with most of the American instruments; the milled heads themselves are thus dropped below the level of the stage, and this is deemed of great importance; this is also the case with Powell and Leland's large microscope.—The usual accessories accompanying the microscope are, an achromatic condenser, a bull's-eye condenser, small condenser, stage and eye-piece micrometers, polarizing apparatus, camera lucida, animalcule cage, stage forceps, glass parabola, erector, Lieberkuhns and dark wells, frog plate, &c. The name of achromatic condenser has been given to an illuminating apparatus consisting of an achromatic objective of large angle, furnished with a wheel of diaphragms and central stops; when the latter are used, oblique illumination is obtained. This condenser is exceedingly useful in the ordinary studies by the microscope. With the proper adjustment it affords a fine achromatic illumination, revealing the structure of the object with great beauty and clearness; but in unskilful hands it will be of little service. So far as oblique illumination is concerned, we prefer unilateral light, though some particulars of structure are best revealed by aid of the achromatic condenser. The condenser is placed below the main stage, and can be adjusted by independent rack-work, so as to give the best illumination. The condenser of 170° angle, lately introduced by Powell and Leland, is spoken of very highly by the English microscopists; the delicate markings of *navicula rhomboidea*, when viewed with their $\frac{1}{4}$ objective, are stated to be as well defined as those of *pl. hippocampus* viewed with a $\frac{1}{2}$. The achromatic condenser of Smith, Beck and Beck has an angle of about 100° . When used with the central stops, the proper point for adjustment may be determined by removing the eye piece, after the objective has been brought into focus, looking down the tube, and moving the condenser by means of its own rack and pinion, until the black stop appears sharply defined in

the centre of the field, and a bright illuminated ring around it. If the stop is removed, the whole field will appear brightly illuminated, unless the objective be of much greater angle than the condenser. A condenser of greater angle than 100° cannot be used unless the object be placed upon very thin glass; all difficult test objects should be mounted in this manner on a slip of mahogany. The condenser itself, or the carrier, should have some means of adjustment to make its axis coincide with that of the objective; the front set of lenses is generally made to be removed, thus affording an illuminator of lower angle, to use with thicker glass and objectives of low power. In using the achromatic condenser by lamp light, the bull's-eye condenser is employed to render the rays parallel, and the plane side of the mirror is used.—The bull's-eye condenser consists of a thick plano-convex lens, of short focus, mounted upon a stand so that it can be used for the illumination of opaque objects. Very excellent oblique illumination may be obtained by condensing the flame of a candle or lamp, placed at a distance of about two feet from the stage, upon the under surface of the slide, the light being placed in front, and the stage slightly turned up to receive it; or, the microscope being placed horizontal, the light may be off at one side, according to the obliquity desired. As the thickness of the stage will not ordinarily allow illumination at a much greater distance than 60° from the axis, a sub-stage, attached to the upper plate of the main stage, but carrying the slide entirely below it, is furnished by Messrs. Grunow, and by Powell and Leland, and may be readily attached to any microscope; this allows illumination of any obliquity. In using the bull's-eye condenser for this purpose with a lamp, the plane side must be presented toward the object; and if the flame be flat, its edge must be presented. The small condenser is used in the same way as the bull's-eye. Where very intense illumination is desired, the bull's-eye is placed near the source of illumination, with the plane side toward it, so as to render the rays nearly parallel, and then this beam of light is further condensed by the small condenser.—The stage micrometer is a slip of glass ruled into .01" and .001" of an inch; it is used in conjunction with the camera lucida, or to determine the value of the divisions of the eye-piece micrometer. The French scale is the millimetre divided into 100 or 200 parts. The eye-piece micrometer is a finely ruled glass scale, introduced by means of an opening between the field and eye lens of the eye piece, so as to be in the focus of the eye lens. The value of the scale is determined by placing the stage micrometer on the stage, and viewing the divisions with the given objective and eye piece, causing by means of the draw-tube a certain number of divisions of the one to correspond exactly with a certain number of the other; thus, if 10 divisions of the eye micrometer corresponded with one (.01") of the stage micrometer, then

the value of one division of the eye-piece micrometer would be .001", with that particular object glass, eye piece, and length of draw-tube. The stage micrometer being replaced by any object, its dimensions may be readily ascertained by noticing how many divisions of the scale are subtended by it. The micrometers of this description are very convenient, and, when carefully used, accurate. The definition is slightly injured, however; this objection is obviated by Mr. Tolles's solid micrometer eye piece. If the observer has only a stage micrometer, the divisions may be projected on paper by means of the camera lucida; then, with the same objective and eye piece, the image of any object being projected on the paper, its dimensions are at once ascertained. Messrs. Powell and Leland furnish a cobweb micrometer susceptible of great accuracy; it is similar to that used for astronomical purposes. Messrs. Grunow have somewhat improved upon Powell and Leland, and their cobweb micrometer with orthoscopic eye piece is a very delicate instrument. They also furnish Fraunhofer's stage micrometer, which possesses the advantage of giving the absolute dimensions of the object, without reference to the power of the objective or eye piece. With careful use the eye-piece micrometer is as accurate as any of these, and much less expensive.—The polarizing apparatus consists of two Nichols prisms of calc spar with revolving fittings, one (called the polarizer) designed to be placed below the object, the other (termed the analyzer) above, either directly over the eye piece, where it generally cuts off part of the field, or at the lower end of the draw-tube; here, if the prism be a good one and not too long, it will not much affect the definition, and will allow the whole field to be visible. Very much depends upon these prisms. Those supplied by the Messrs. Grunow are very large and fine, and the analyzer is placed by them directly above the objective; it is too large, however, to be placed so low down without injury to the definition. The analyzer of Smith, Beck, and Beck is much shorter than Grunow's, and may be used either over the eye piece or placed in the end of the draw-tube. There is much difference in these prisms; some scarcely injure the definition at all, and others are very poor. The polarizer is usually somewhat larger than the analyzer. The calc spar is very soft, and, if not protected by thin glass covers, as are those of Messrs. Grunow, liable to injury. A set of revolving selenites, to be placed below the object, between it and the polarizer, is supplied both by Grunow and by the English opticians. There is not much choice in the method of mounting and revolving these prisms; perhaps Grunow's is the most elaborate, but when the revolving selenites are included, we think Smith, Beck, and Beck's arrangement the most complete. A "selenite stage" is often employed, simply placed under the object, on the stage of the microscope. Mr. Daker has contrived a stage of this kind, in which the

selenites revolve. A complete polarizing apparatus is very important, and should be attached to every good instrument. Sometimes tourmalines are used instead of the prisms of calc spar; they are objectionable on account of their color, but placed over the eye piece do not at all obstruct the field of view.—The camera lucida furnishes the means of drawing or sketching outlines of objects viewed in the microscope, some provision for which is absolutely necessary. Often this is merely a plate of neutral tint glass, which, placed in front of the eye piece, at an angle of 45° , when the microscope is turned horizontal, reflects the image to the eye, and at the same time pencil and paper upon the table may be viewed through the glass. A better contrivance than this is the steel disk of Soemmering, made slightly smaller than the pupil of the eye; this, when placed in front of the eye piece, enables one to view object and paper at the same time. In these contrivances, and also in the Nachet drawing prism, the object, being viewed after but one reflection, is reversed right and left. Where it is necessary to finish a drawing by the eye, this is a serious difficulty; it is therefore preferable in all cases to use the Wollaston prism, which is applied so as to give an unobstructed view of the whole field, and with which the drawing is precisely as it appears in the microscope without the prism. A little practice is required to use it well, but if the observer will take care to have the paper strongly illuminated, while the object is only enough illuminated to see it distinctly, no great difficulty will be found.—The animalcule cage is a simple contrivance by means of which a drop of water may be retained between two glass plates, which may be approximated so as to just confine the object, without allowing, if it be living, too much freedom of movement; it is often made to serve the purpose of a compressor, for crushing soft bodies more or less during the examination.—The stage forceps is exceedingly useful for the examination of small insects. At one end is usually placed a bit of cork, enclosed in a brass cylinder pierced with holes, to receive an insect pin, in case it be desirable to examine cabinet specimens. The forceps should have free movement in all directions. The recent ones supplied by Smith, Beck, and Beck have a ball and socket movement; they are attached to the upper stage plate, and thus are moved by the rack and screw of the stage.—The parabola was originally contrived by Mr. Wenham, and was composed of a silver reflector; it is now made of glass, the outer surface having the form of a parabola. The rays of light, entering the glass through a plane surface below, suffer total reflection, and emerge without refraction, the upper surface of the truncated parabola being concave, so that each reflected ray strikes upon the surface perpendicularly. The glass parabola has a small hole in the axis, carrying a sliding rod, with a small disk, which may be elevated or depressed according to the

angle of aperture of the objective, until the direct light is excluded; the object is then exhibited entirely by oblique light on a dark field. The *polycystina* are beautifully shown by this illumination, and also parts of insects with the lower powers.—The erector consists of two plano-convex lenses, to be inserted into the lower end of the draw-tube; by means of these the object is seen without being inverted. The magnifying power is much diminished, and the definition injured; and one who intends to dissect under the compound microscope, had better at once learn to manipulate without it. The ingenious erecting prism of Nachet may be used, which does not in the least injure the definition. In this case the upright stand of Nachet will be found very steady and convenient.—Lieberkuhns are polished silver specula fitted to the lower powers, the polished surface being presented to the object; they are used in conjunction with what are termed dark wells, which consist of a slender rod carrying at the summit a blackened cap of brass, and are placed directly under the object so as to cut off the direct light; where the object itself is mounted on an opaque background, they are unnecessary. The light reflected from the mirror below, falling upon the Lieberkuhn, is condensed upon the object. There are many opaque objects which cannot be well seen without this kind of illumination, and it is justly considered a very important addition to the apparatus.—The frog plate is a flat mahogany or metal plate, having a slightly elevated glass platform, and the edge of the plate pierced with holes or furnished with split pins. By means of threads tied to the toes of the frog, the web may be spread out on the plate, the body of the frog being enclosed in a bag and strapped to the plate; care must be taken not to draw the string too tightly around the mouth of the bag where the leg protrudes, as it stops the circulation. The bag may be dispensed with by holding the frog a moment or two in water of 120° F., when it becomes perfectly rigid and apparently insensible. In this condition it may be opened, and the circulation of the blood in the veins and arteries of the mesentery most beautifully exhibited; care must be taken to keep the parts moist. For the purposes of minute dissection we have found the eye instruments exceedingly useful. Fine scissors and forceps are made for this purpose, of most excellent quality, by Charrière of Paris, and may be had of the dealers in surgical instruments.—In working with the microscope, one should acquire the habit of keeping both eyes open. If the eyes are allowed to rest easy, and then the focus carefully adjusted to suit while thus resting, no great fatigue will be experienced in using the microscope; if, however, the focus is only approximated, and then distinct vision obtained by forcing the eye, severe pain and headache will ensue. The writer has worked with a bright light for 6 or 8 hours, with but slight intermission, without fatigue. Long experience and great caution are requisite in in-

terpreting the phenomena revealed by the microscope, and one soon learns that things are not always what they seem. This, however, cannot be justly urged against its use. When directed by skilful hands, and guided by experience, its revelations are of the most exalted and truthful character. No one can hope to succeed in the department of natural history who is not a skilful microscopist. A north light, coming from the left hand, the stage movements being at the right hand, is the best light for day. At night, the naphtha or coal oil lamp, as now made by Smith, Beck, and Beck, gives the most intense and steady flame. The gas jet is difficult to manage for delicate work.—We have not yet noticed the “test objects.” Many of these have been so long known that it seems almost unnecessary to mention them. The markings on the silicious shells of diatoms have been highly recommended. As general tests, they are no doubt very serviceable, but they are not entirely to be relied upon unless the same specimen is used in comparisons, on the same stand, and with the same illumination. In the following table the usual tests, both for direct and oblique illumination, are given :

Objective, inches.	Angle of aperture.	Direct light.	Oblique light.
2 or 1½	20°	Sections of echinus, of wood.
1	28°	Pollen grains, &c.	Pinnularia viridis.
¾	33°	Tracheæ of insects.	Cocconeis lanceolatum.
⅔	80°	Pleurosigma attenuatum.	Pleurosigma fasciola.
⅕	100°	Pleurosigma strigosum.	Hyalodiscus Californicus.
⅓	140°	Pleurosigma fasciola.	Navicula rhomboides.
⅓ or ⅓	170°	Do. do.	Grammatophora subtilissima of Providence.

The following table exhibits the lineation of different species of *diatomacea* which have been employed as tests ; the measurements are those of Messrs. Sullivant and Wormley :

	Tests.	Striae in 1-1000 of an inch.
1.....	Pleurosigma formosum.	86 diag.
2.....	“ strigillo.	80 trans.
3.....	“ Balticum.	86 “
4.....	“ attenuatum.	86 “
5.....	“ hippocampus.	88 “
6.....	“ strigosum.	42 diag.
7.....	“ quadratum.	45 “
8.....	“ elongatum.	48 “
9.....	“ lacustre.	42 trans.
10.....	“ angulatum.	50 diag.
11.....	“ fasciola.	56 trans.
12.....	Navicula rhomboides.	70 “
13.....	Nitzschia sigmoidea.	70 “
14.....	Colletonema vulgare.	72 “
15.....	Grammatophora subtilissima, Greenport.	70 to 75 trans.
	Do. do. Providence.	75 to 80 “
16.....	Synedra capitata, hoop of.	said to be 75 “
17.....	Amphipleura pellucida.	180 “

About the last we have great doubts; Mr. Sollitt and Mr. Lobb claim to have resolved it. From experiments with the Nobert test plate, and from the most careful examination with the best English and American objectives, the most

experienced American microscopists believe there is some mistake in this supposed resolution. In judging of the merits of an objective, it appears to us oblique illumination has been too much dwelt upon. The angle of aperture having been ascertained, the general merits will be much more apparent by use of tests, Nobert's lines for example, with the best central illumination. If the scale of *podura plumbea* is employed, select a medium-sized rather than a large one. The wedge-shaped dots should be sharply defined, without fog or mist. The scales of the American *podura* are not dotted but lined, and are not so suitable.—See Robin, *Du microscope* (Paris, 1849); Hartung, *Het Mikroskopen* (Utrecht, 1852; translated into German by Dr. Theile, Brunswick, 1859); Quekett “On the Use of the Microscope” (2d ed., London, 1852; Wythes, “The Microscopist” (Philadelphia, 1853); Schacht, “The Microscope,” edited by Currey (London, 1855); Griffith and Henfrey, “Micrographic Dictionary: Introduction” (London, 1856); Beale, “How to work with the Microscope” (London, 1857); Carpenter, “The Microscope and its Revelations” (London and Philadelphia, 1857); Hogg, “The Microscope” (London, 1858); Gosse, “Evenings at the Microscope” (London and New York, 1859); West, “Half Hours at the Microscope” (London, 1859); Beale, “Application of the Microscope to Clinical Medicine” (2d ed., London, 1859); Clarke, “Objects for the Microscope” (London, 1859); “Transactions of the Microscopical Society of London;” “Quarterly Journal of Microscopical Science” (London); and Sir David Brewster's paper read at the meeting of the British association for the advancement of science, 1860, on “Microscopic Vision and a new Form of Microscope.”

MICROSCOPIO ANIMALS. See ANIMALCULES.

MIDAS, a mythical king of Phrygia, son of Gordius, and, according to some authorities, of Cybele. Having conferred a favor on Bacchus, the god desired him to ask whatsoever he pleased. Midas requested that every thing touched by him should be transformed into gold. The request was granted, but as his food underwent the metamorphosis as well as all things else, he was reduced to a state of starvation, and implored the god to recall his grant. Bacchus bade him bathe in the Pactolus; and Midas having done so, instantly his touch lost its auriferous power in the case of all things essential to life, while the sands of the river were converted into gold. Midas was once chosen umpire in a musical contest between Pan and Apollo; he awarded the palm to Pan, in revenge for which Apollo changed his ears into those of an ass. Midas, to hide this deformity, used to wear a lion's cap; but the slave whose business it was to cut his hair became privy to the secret, which so troubled him that, afraid to reveal it to a fellow mortal, and unable to keep it to himself, he dug a hole in the earth, and whispered into it: “King Midas has asses' ears.” He then filled up the hole, but a reed sprang up on the spot which

as often as the wind blew, whispered his words to the world. Midas is said to have killed himself by drinking the blood of an ox.

MIDDELBURG, or **MIDDLEBURG**, a town of Holland, capital of the province of Zealand, situated near the centre of the island of Walcheren; pop. in 1856, 14,000. The town is circular, and surrounded by a ditch and a mound, the top of which forms a favorite public promenade. It has several excellent educational establishments, and various manufactures. The town hall was built by Charles the Bold in 1468, and is ornamented with 25 colossal statues of counts and countesses of Flanders. The town was founded in 1182, and was taken by the Dutch from the Spaniards in 1574. The British lost 7,000 men here from the effects of the climate during the famous Walcheren expedition in 1809.

MIDDLE AGES. See **HISTORY**.

MIDDLEBURY, a township and village, capital of Addison co., Vt., on both sides of Otter Creek river at Middlebury falls, and on the line of the Rutland and Burlington railroad, 81 m. S. from Burlington and 59 m. from Montpelier; pop. in 1850, 8,157. A marble quarry at this place, affording some fine qualities for statuary, is worked by a company, and yields large quantities for exportation. It is the seat of Middlebury college, founded in 1800, and having in 1859 a president, 6 instructors, 85 students, 984 alumni, and a library of 9,000 volumes. There are in the village a cotton factory, a woollen factory, a grist mill, and an iron foundry actively employed, a court house, a bank, and 5 churches (Baptist, Congregational, Episcopal, Methodist, and Roman Catholic). The township contains 2 post offices, an academy, a female seminary, and a number of schools.

MIDDLESEX, the name of counties in 4 of the United States. I. A N. E. co. of Mass., bordering on N. H., bounded S. E. partly by the river Charles, and drained by the Merrimack, Nashua, and Concord rivers, and other streams; area, 888 sq. m.; pop. in 1855, 194,023. The agricultural productions in 1855 were 560,329 bushels of potatoes, 331,934 of Indian corn, 76,674 of oats, and 46,822 of rye. The immense water power supplied by a number of streams is largely employed in manufactures, in which the industry of the people is principally engaged. In 1855 there were 48 cotton, 10 woollen, 4 carpet, and 3 rolling mills; 2 calico, 8 worsted, 4 glass, 13 hat and cap, and 21 paper manufactories, 61 of railroad cars and other vehicles, and 10 of patent and enamelled leather; 39 currying establishments, and 23 tanneries. There were 1,388,119 pairs of boots and 6,527,105 pairs of shoes made; and 4 daily and 10 weekly newspapers were published. The value of the productions of the county of all kinds in 1855 was \$58,205,633. In 1850 there were 204 churches, and 26,233 pupils attending public schools. Several railroads intersect the county, and others connect the principal towns, including Boston. Shire towns Concord, Cambridge, and Lowell. II. A S. co. of Conn., bordering

on Long Island sound, and intersected by the Connecticut river, which also forms a part of its E. boundary; area, about 480 sq. m.; pop. in 1850, 30,680. The surface is somewhat uneven and the soil generally fertile. Several streams furnish water power, and there are a number of manufactories. The productions in 1850 were 228,788 bushels of potatoes, 95,118 of Indian corn, 50,549 of rye, 28,510 of oats, 28,409 lbs. of wool, 501,128 of butter, and 38,579 tons of hay. There were 8 cotton, 11 woollen, and 2 paper factories, 9 grist and 40 saw mills, 2 founderies, 7 tanneries, 4 newspaper offices, 65 churches, 1 college, and 7,087 pupils attending public schools. The New Haven and New London railroad passes through the southern part of the county. Shire towns, Middletown and Haddam. III. A central co. of N. J., intersected by the Raritan river, and bounded E. by Raritan bay and Staten Island sound; area, 889 sq. m.; pop. in 1855, 82,408. The surface is level toward the S. E. and undulating in the N. and N. E.; and the soil, which varies from a light sand to a deep clay, is generally fertile. The productions in 1850 were 488,668 bushels of Indian corn, 218,954 of oats, 128,076 of potatoes, 78,022 of wheat, 501,648 lbs. of butter, and 5,587 of wool. There were 8 distilleries, 8 cotton factories, 8 India rubber manufactories, 14 flour and 20 saw mills, 8 potteries, 7 tanneries, 47 churches, 5 newspaper offices, and 8,221 pupils attending public schools. The Camden and Amboy and the New Jersey railroads traverse the county, the latter passing through the capital, New Brunswick. IV. A S. E. co. of Va., bordering on Chesapeake bay at the mouth of the Rappahannock river, which forms its N. E. boundary, and bounded S. W. by the Piancotank river; area, 170 sq. m.; pop. in 1850, 4,894, of whom 2,842 were slaves. It has a sandy, but fertile soil. The productions in 1850 were 184,258 bushels of Indian corn, 80,762 of wheat, and 5,280 lbs. of wool. There were 8 grist mills, 5 saw mills, 1 tannery, 9 churches, and 152 pupils attending public schools. Value of real estate in 1856, \$856,296, being an increase of 21 per cent. since 1850. Capital, Urbana.

MIDDLESEX, a S. W. county of England, bounded N. by Hertfordshire, E. by Essex, S. E. by Kent, S. by Surrey, and W. by Surrey and Buckinghamshire; area, 282 sq. m.; pop. in 1851, 1,886,576. It is the smallest county in the kingdom except Rutland, but the greatest in population, wealth, and importance, its capital being London, which occupies 51 sq. m. of the county. Much of the land is devoted to market gardening, though more of it is in meadow and pasture, the cows kept for the supply of the metropolis with milk numbering over 7,000. Middlesex is divided into 6 hundreds and 208 parishes, 118 of which are within the cities of London and Westminster. It returns 14 members to parliament, 2 of whom are for the county. The chief towns, beside London, are Brentford, Staines, and Uxbridge.

MIDDLE THIBET. See **LADAKH.**

MIDDLETON, the name of a distinguished family in the history of South Carolina. I. **EDWARD**, its founder, was a native of Twickenham, England, where he inherited a large property, which is still owned by one of his descendants. He removed to South Carolina, and was one of the members of the council under the lords proprietors in 1680, little more than 10 years after the first settlement of the colony. He evinced decided republican tendencies, and opposed the governors in favor of popular rights and privileges. II. **ARTHUR**, son of the preceding, was conspicuously engaged in public affairs as a member of the council as early as 1712. His property and talents gave him political influence, which he exerted in favor of popular claims, opposing the close borough system of the lords proprietors, and finally heading the revolution which threw off the whole proprietary government and placed the colony under the immediate protection of the crown (1719). He was probably the writer of the plan of association, which was submitted to the people at a militia gathering, for uniting the opposition movement throughout the province. He was president of the popular convention which declared the proprietors to have forfeited their rights under the charter, a declaration which was subsequently confirmed by a decision under the crown; and he was the spokesman in the proceedings by which the governor was formally deposed by the popular government. In 1725 he succeeded Nicholson as governor of the colony, which office he held till 1731, after which he remained in the royal council. His administration was partly occupied by war and negotiations with the Spaniards of Florida and the French of Louisiana. Hewitt, the historian of South Carolina, who regarded unfavorably his republican tendencies, speaks of him in terms of moderate praise. III. **THOMAS**, third son of the preceding, distinguished himself in 1761 in command of a provincial regiment against the Cherokees, coöperating with Col. Grant, who was at the head of the regulars. A disagreement ensuing, he caned the colonel in the streets of Charleston, and a duel with pistols followed, but neither party was hurt. The affair led to great bitterness of feeling between the natives and the British residents. IV. **HENRY**, brother of the preceding, was an aged man at the outbreak of the revolution, but was sent as a delegate from South Carolina to congress, of which body he was president in 1775. He was an invalid on his plantation during most of the period when South Carolina was in possession of the British. V. **ARTHUR**, son of the preceding, and a signer of the declaration of independence, born at the family seat on Ashley river in 1748, died Jan. 1, 1787. At the age of 15 he was sent to Harrow school, England, whence he passed to Westminster school, and in 1764 to the university of Cambridge, where he took his degree. He returned to America, married, and soon

after revisited Europe, and made a tour of two years on the continent. On his return he established himself as a planter, but was soon prominent as a leader of the revolutionary party in South Carolina. He was one of the most decided and efficient members of the first council of safety. His correspondence at that time with William Henry Drayton is especially interesting and valuable for the light which it throws on the social condition of the colony. Its interests, being chiefly agricultural, suffered little from British hostility; many of the inhabitants were British by birth; this colony, moreover, had been particularly favored by the government of the Georges; and it therefore required all the eloquence and ability of the principal citizens to reconcile the body of the people to the revolution. In this cause Mr. Middleton was one of the most zealous. In 1776 he was sent as a delegate of the state to congress, and as such affixed his signature to the declaration of independence. He and Hancock were very intimate, lodged together, and dispensed a liberal hospitality, which made their hotel a favorite place of reunion for distinguished persons. He held his seat in congress until 1777, declined the governorship of South Carolina in 1778, took the field for the defence of Charleston in 1779, saw his plantation devastated by the British, was made a prisoner after the fall of Charleston in 1780, and was one of the leading citizens who were kept in confinement as hostages. His estate was sequestered, and he was shipped to the castle of St. Augustine, and thence transferred to the Jersey prison ship. Exchanged in the latter part of 1780, he served till the close of the war as a delegate in congress, and was afterward elected to the state senate. He was a skilful stenographer, a rare accomplishment at that time, and took down many of the debates in which he participated. He wrote effective political essays under the signature of "Andrew Marvell." VI. **JOHN IZARD**, second and youngest son of the preceding, born at the family seat on Ashley river in 1785, died in Paris in Nov. 1849. He was educated at the university of Cambridge, England, and remained abroad to gratify his tastes for art, poetry, and music. During the last 25 years of his life he resided in Paris. In 1810 he married the daughter of M. Falcouet, the banker of Naples, and was afterward received on intimate terms in the circles of Mme. de Staël and Mme. Recamier. His work on "The Cyclopean Walls" (fol., London, 1812) shows his familiarity at once with classical literature and with the details of art. VII. **HENRY**, son of Henry Middleton, who was for many years U. S. minister to Russia, born in 1797, in Paris where his family was sojourning during a tour of pleasure. He was educated in South Carolina under private tutors till the age of 16, when he was sent to West Point, where he was graduated. He afterward attended the law lectures in Litchfield, Conn., pursued the study for two years in Europe, and was admitted to the bar in Charleston in 1822. He has never practised

the profession, but has devoted himself to writing on topics of government, politics, and political economy. He visited Europe in 1835, and remained several years; repeated his visit in 1850, married in England, and returned in 1859. His publications include many small volumes and pamphlets, chiefly on current political and economic questions.

MIDDLETON, CONYERS, D.D., an English clergyman and scholar, born in Richmond, Yorkshire, Dec. 27, 1683, died in Hildersham, Cambridgeshire, July 28, 1750. He was graduated at Trinity college, Cambridge, in 1702, was ordained deacon soon afterward, was elected a fellow of his college in 1706, and in 1708 signed the petition against Bentley, the master. This was the commencement of a controversy between Middleton and Bentley, long continued within the walls of the university, in pamphlets, and in the courts of law. When Middleton with 8 others in 1717 was nominated D.D. by the king, Bentley, who was then regius professor of divinity, would only grant them the degree on payment of 4 guineas over the usual fee. Middleton complied with the demand, but brought the case before the vice-chancellor; and Bentley, refusing to acknowledge the jurisdiction of that officer, was dismissed from his professorship and stripped of all his degrees. Middleton published two pamphlets giving an account of the affair, which first attracted attention to him as a polished and learned writer. Soon afterward he put forth another pamphlet on the government of Trinity college as administered by Bentley. Having stated in it that there was no court in the kingdom before which the fellows could bring their complaints, his great adversary sued him for libel on the administration of justice in the kingdom, and the jury found him guilty; but sentence was suspended on Middleton's begging Bentley's pardon and paying the costs. When Bentley published proposals and a specimen for a new edition of the Greek Testament, Middleton attacked it in a severe critique, and descended to the lowest personal abuse. Bentley revenged himself in 1723 by prosecuting him for a libel on the court of king's bench, in the dedication of a plan which he had drawn up for arranging the university library (of which he had been made principal librarian, an office created expressly for him), and he was fined £50. In 1726 Middleton published an attack upon the medical profession, entitled *De Medicorum apud Veteres Romanos degentium Conditione Dissertatio*. In 1729 appeared his "Letter from Rome" (which he had visited in 1724), in which he attempted to show that "the religion of the present Romans was derived from their heathen ancestors." He also attacked the miracles of the Roman Catholic church in a way which awakened a suspicion of his disbelief in the miracles of the New Testament. A letter to Dr. Waterland published in 1731 gave still more serious offence to the clergy, and Middleton found it necessary to publicly avow his be-

lief in Christianity, but his avowal received little credit. He held that the Gospels were full of contradictions, that the apostles were sometimes mistaken in their application of the prophecies to Christ, and that the account of the fall of man was a fable or allegory. About this time he was appointed to the Woodward professorship of natural history, but soon resigned it. In 1735 he published "A Dissertation concerning the Origin of Printing in England," and in 1741 his most popular work, "The History of the Life of M. Tullius Cicero" (2 vols., London), which Macaulay calls "a lying legend in honor of St. Tully." This was followed by a translation of the correspondence of Cicero and Brutus, together with a defence of its authenticity (1748), and a "Free Inquiry into the Miraculous Powers which are supposed to have subsisted in the Christian Church from the Earliest Ages" (1749), which exposed him again to the charge of infidelity, and was generally condemned as subversive of religion. In 1750 appeared his "Examination of the Bishop of London's (Dr. Sherlock) Discourses concerning the Use and Intent of Prophecy." His works, with the exception of the "Life of Cicero," were collected and published in 1752, in 4 vols. 4to.

MIDDLETON, THOMAS, an English dramatist, born in the latter part of the 16th century, died in July, 1627. Almost the only event of his life known to us is that he was appointed chronologer or city poet of London in 1620. Jonson, in a letter to the earl of Newcastle in 1631, says in reference to the salary connected with this office: "Yesterday the barbarous court of aldermen have withdrawn their chauntury pension for verjuice and mustard—£38 6s. 8d." He was associated with Jonson, Fletcher, Massinger, and Rowley in the composition of several plays. His own productions are very numerous; three of them, "A Mad World, my Masters," "The Mayor of Queenborough," and "The Roaring Girl," are in Dodsley's collection. His "Game at Chess," performed in 1624, gave umbrage to the court on account of its allusions to the king and ambassador of Spain, and Middleton and the players were brought before the privy council and censured for their audacity in "bringing modern Christian kings upon the stage." A play of his called "The Witch" is that whence Shakespeare has been supposed to have borrowed the witchcraft scenery and part of the incantations in "Macbeth;" although it is not improbable that the reverse was the case, and that Middleton borrowed his play from Shakespeare.

MIDDLETON, THOMAS FANSHAW, D.D., an English classical scholar, born in Kedleston, Derbyshire, Jan. 26, 1769, died in Calcutta, July 8, 1822. He was educated at Christ's hospital, London, and Pembroke hall, Cambridge, received orders, and enjoyed various preferments. He edited for some time a periodical called the "Country Spectator," and wrote "The Doctrine of the Greek Article applied to the Criticism and Illustration of the

New Testament" (London, 1808). When Calcutta was erected into an episcopal see, he was made its first bishop, and was consecrated at Lambeth, May 8, 1814. Some of his sermons, charges, and tracts were collected and published in London in 1824, by Dr. H. K. Bonney.

MIDDLETOWN, a township, city, port of entry, and half shire town of Middlesex co., Conn., on the right bank of the Connecticut river, at the head of ship navigation, 23 m. from its mouth, 24 m. N. E. from New Haven, 15 m. S. from Hartford, and 85 m. N. W. from New London; pop. of the township in 1860, 8,688; of the city, 5,188. The city has a gradual ascent from the river, with which the principal streets run parallel, crossed at right angles by others; it is well built, chiefly of brick, and has many fine situations and elegant mansions in the environs. It has a custom house built of Oatham freestone, and a court house. It is the seat of the Wesleyan university, under the direction of the Methodists, and of the Berkeley institute, an Episcopal divinity school. In 1860 Middletown had 16 churches (1 African, 2 Baptist, 5 Congregational, 2 Episcopal, 8 Methodist, 1 Roman Catholic, 1 Scotch Presbyterian, and 1 Universalist), 3 banks of issue and 4 savings banks, 6 grist mills, 5 saw mills, 8 cotton factories, 8 iron foundries, and various other manufacturing establishments. The wharfs have 10 feet of water, and can accommodate such vessels as can cross the bar. The tonnage of the district in 1859 was 15,117, of which 8,578 was steam.

MIDGE, a small fly. See **DIPTERA**.

MIDIANITES, a nomad or half-nomad people of northern Arabia, who, in the time of the early history of the Hebrews, dwelt in the vicinity of the Red and Dead seas, especially between Mt. Sinai and Moab. They are derived in Scripture from Midian, the son of Abraham by Keturah, and appear occasionally as merchants, and more frequently, like Bedouins, making raids into the neighboring territories of the Jews. Moses, who was himself the son-in-law of a Midianite priest, Jethro, waged a war of extermination against those of their tribes who in conjunction with the Moabites had enticed the Hebrews to idolatry when they were approaching Canaan. Gideon seems to have broken their power by his great victory over them and their allies the Amalekites. Some critics, in order to remove difficulties arising from apparently contradictory scriptural statements about this people, distinguish between Abrahamite and Cushite tribes of the same name, the former of whom, descendants of the same Semitic stock, lived in hostility to the Hebrews, while the daughter of Jethro is identified with the Cushite wife of Moses, mentioned in another part of his history (Num. xii. 1).

MIDLAND, an E. co. of the southern peninsula of Mich., bordering on Saginaw bay, intersected by Tittibawassee river, and drained by its branches, the Chippewa, Salt, and Pine rivers; area, 650 sq. m.; pop. in 1850, 65. The

surface is level and the soil fertile. The productions in 1850 were 1,650 bushels of corn, 750 of potatoes, 50 tons of hay, and 128 lbs. of wool. Capital, Midland City.

MIDLOTHIAN. See **EDINBURGHSHIRE**.

MIDSHIPMAN, the junior grade of officers in the line of promotion in the naval service. The number of midshipmen and passed midshipmen in the U. S. navy is limited by law to 464, and no one can be appointed unless he is a graduate of the naval academy at Annapolis, Md. The members of this institution are denominated "acting midshipmen," and the appointments are distributed by law among the states and territories which have not their relative proportion on the navy list; and it is further required that the appointments from each state shall be apportioned as nearly as practicable equally among the several congressional districts therein; that the person appointed shall be an actual resident of the congressional district from which he is appointed, and be recommended by the member of congress for that district. Candidates must be over 14 and under 18 years of age at the time of the examination for admission; must be free from deformity, disease, or imperfection of the senses; must be of good moral character, able to read and write well, writing from dictation, and spelling with correctness, and to perform with accuracy the various operations of the ground rules of arithmetic, viz., numeration, and the addition, subtraction, multiplication, and division of whole numbers. The examinations to which they are subjected upon these points are, first, by a board of three surgeons, and then by one of professors. If found qualified, they become members of the academy, their actual travelling expenses from their place of residence to the institution are paid by the government, and they are placed upon a pay of \$500 per annum. The course of instruction at the naval academy, which embraces a period of 4 years, includes mathematics, astronomy, navigation and surveying, ethics and English studies, natural and experimental philosophy, French and Spanish, drawing, artillery and infantry tactics, practical seamanship, naval gunnery both theoretical and practical, the steam engine, &c. During the academic course 2 cruises of about 8 months each are made in a ship of war for instruction. Warrants as midshipmen are conferred upon the graduates of the academy, who take rank in the order of merit. After 2 years of actual sea service, midshipmen, if they produce a favorable testimonial from their commanders, are entitled to a final examination for promotion, which is made by a board composed of 3 captains and 2 commanders. This examination is on the practical branches of the profession, and includes seamanship and naval tactics, practical navigation, gunnery, and the steam engine. Having passed this, they receive new warrants as passed midshipman, with increased pay; and promotion to the higher grades of the service, which are master, lieutenant, commander,

der, and captain, is open to them.—In the British navy, young gentlemen intended for commissioned officers are educated, in the first instance, at the royal naval college; and afterward, while serving at sea and until their promotion to a higher grade than midshipman, they are obliged to devote a portion of their time to study under the superintendence of a competent "instructor," who is often the chaplain of the vessel. Some of the appointments from the college are made directly by the lords of the admiralty, and others by the commander of a ship making selections from among the pupils at college, subject afterward to their lordships' approval. The first 18 months' service afloat are passed as "cadets," and the next 3½ years as midshipmen; when, provided they pass the requisite examination to qualify them to become lieutenants, and are 19 years of age, they are rated mates. The pay of a cadet is £16 14s. 7d. per annum, and that of a midshipman £31 18s. 9d. They are considered as the principal petty officers, and rank comparatively with ensigns in the army, but have no specific duties assigned to them. In smaller vessels some of the senior midshipmen are intrusted with the watch; they take charge of boats and small parties of men going ashore, pass the word of command, and see that the orders of their superiors are carried into effect. A midshipman's share of prize money is the same as that of a petty officer, a cadet's equal to that of the captains of the tops; and both receive the rations of seamen. There is no limit put by law to the number at any time in the British service; but it is regulated by the number and class of ships in commission, each description of vessel being allowed a certain fixed complement of midshipmen.—The French *aspirants de marine* occupy a similar position and perform similar duties to those of the midshipmen of the American navy. They are of two classes; are especially educated for their profession at the naval academy at Brest, and undergo a strict examination before receiving their appointment afloat, where they serve from the age of 12 to 20 years. They are not entitled to command a ship till they have attained the age of 21.

MIDWAY, a village of Baldwin co., Ga., on the Milledgeville and Gordon railroad, 1½ m. S. from the former; pop. in 1850, about 800. It is the seat of Oglethorpe university (Presbyterian), founded in 1888, which in 1859 had a president and 4 professors, 97 students, 231 alumni, and a library of 4,500 volumes.

MIDWIFERY. See OBSTETRICS.

MIEL, JAN, called by the Italians Giovanni della Vita, a Flemish artist, born near Antwerp in 1599, died in Turin in 1664. His easel pictures of fairs, carnivals, hunting parties, market scenes, gypsies, &c., are his best works.

MIERIS. I. FRANCISUS, the elder, a Dutch painter, born in Leyden in 1635, died in 1681. He was a pupil of Gerard Douw, and painted pictures of *genre*, and occasionally portraits, all remarkable for delicacy of finish, accuracy

of drawing, and correctness of design. His pictures are not numerous, and bring very large sums. He died a prisoner for debt in consequence of an extravagant course of life. II. WILHELMUS, son of the preceding, born in Leyden in 1662, died there in 1747. He was the pupil of his father, and equalled him perhaps in delicacy of finish, though he was inferior in color, drawing, and design. He attempted historical subjects in combination with landscape, and a picture by him of Rinaldo asleep on the lap of Armida became so popular that he was obliged to paint a number of copies. His domestic subjects are held in high estimation and bring large prices. III. FRANCISUS, the younger, son of the preceding, born in Leyden in 1689, died in 1768. He studied painting with his father, and executed similar subjects, although in a much inferior manner. He also made numerous copies of the works of his father and grandfather, which frequently pass for originals with inexperienced purchasers. He was an industrious student of history, and wrote a number of works in Dutch relating to the Low Countries, including a *Historie der Nederlandische Vorsten* (3 vols. fol., the Hague, 1782-'5), and *Groot Charterboek der Graven van Holland, Zeeland en Vriesland* (4 vols., Leipsic, 1753-'6). He was engaged upon a history of Leyden at the time of his death.

MIEROSLAWSKI, LUDWIK, a Polish writer and general, born in Nemours, France, about 1818. He is the son of a Polish officer, who had served in the army of the duchy of Warsaw and under Davoust, by a French woman, and was educated at the military school in Kalisz. He joined the revolutionists in 1830, served with distinction in the campaigns of the following year, and after the fall of Warsaw removed to France, dividing his time in Paris between pleasure and study. He published various books, mostly of little value, in Polish and French, and among others some works on the Polish revolution of 1830-'31, which gained him a reputation as a writer on military affairs. He became the idol of the younger part of the Polish emigrants, and was finally selected by the democratic organization at Paris as principal leader for the next rising of Poland. This failed, however (1846), and Mieroslawski, who had arrived in Prussian Poland, was arrested, tried at Berlin with a number of his fellow conspirators, and sentenced to death. He showed himself worthy of the high position he had assumed by his courage and dignity during the trial; but when the Berlin revolution of March, 1848, opened his prison, and he received a public ovation in the capital of his enemy, he immediately hastened to the duchy of Posen, and inconsiderately armed for another Polish rising. The new Prussian ministry, which at first made the most encouraging promises in favor of Polish liberty, soon adopted a different policy, and a bloody conflict was the result. The Poles, in small unorganized bands, mostly without cannon and ammunition, fought with desperate valor, and

gained a signal victory at Miloslaw; but after some reverses Mieroslawski resigned his command, and the insurgents were disarmed (May, 1848). He returned to Paris, whence he was summoned to Sicily early in the following year, to take command of the revolutionary forces. The affairs of the island were in a desperate condition, and Mieroslawski, who was wounded in the defence of Catania (March, 1849), left his post. Once more he took command of a revolutionary army in Baden, but with still slighter chances of success; and after a few encounters with the Prussians he was obliged to retire to the fortress of Rastadt, which surrendered soon after (July, 1849). He again returned to Paris, and has since published several new works on the history of Poland.

MIFFLIN, THOMAS, an American revolutionary general, born in Philadelphia in 1744, died in Lancaster, Penn., Jan. 20, 1800. He was by birth and education a Quaker, and, after a tour through Europe, commenced business in Philadelphia with his brother. He entered public life in 1772 as a representative from Philadelphia in the colonial assembly, and in 1774 he was a delegate to the first continental congress. At the first outbreak of hostilities in Massachusetts he enrolled himself in the military service, and in June, 1775, accompanied Washington to Cambridge as his first aide-de-camp, with the rank of colonel. He subsequently held the appointment of adjutant-general, and in the spring of 1776 was commissioned as a brigadier-general. He fought with reputation in the battle of Long island, and by his energy succeeded in the latter part of 1776 in raising considerable reinforcements in Pennsylvania to recruit the thinned ranks of Washington's army. He was present at the battle of Trenton, and did good service in driving back the enemy's line of cantonments from the Delaware. In 1777 he was made a major-general, and in the same year became an active member of the faction organized for the purpose of placing Gates at the head of the continental army, and known in history as the "Conway cabal." The project failing, he resigned his commission, and in 1788 was elected to congress, of which body he became president at the close of the same year. In this capacity he received from Washington the resignation of his commission as commander-in-chief. In 1785 he became speaker of the Pennsylvania legislature, and in 1787 he was a member of the convention which framed the federal constitution. In Oct. 1788, he succeeded Franklin as president of the supreme executive council of Pennsylvania, which position he filled for two years; and in 1790 he was chosen governor of Pennsylvania under the constitution adopted in that year. In 1794, while holding this office, he rendered important assistance to Washington in quelling the "whiskey" "insurrection." He held the office of governor for 9 years, and died soon after returning to private life.

MIGNET, FRANÇOIS AUGUSTE ALEXIS, a French historian, born in Aix, May 8, 1796.

He was educated in Avignon, and in 1815 commenced the study of law in his native city, where Thiers became his fellow student and friend. In 1818 he was called to the bar, and two years later obtained a prize offered by the academy of Nîmes for an essay on Charles VII. The acquisition in 1821 of a more important prize proposed by the academy of inscriptions and belles-lettres, for a dissertation on the state of the government and legislation of France during the age of Louis IX., induced him to abandon the law for the pursuit of letters, and in company with Thiers he removed to Paris. His liberal political views soon recommended him to the editor of the *Courrier Français*, to the staff of which he remained attached for upward of 10 years; and about the same time he commenced a course of historical lectures at the Athénée which gained him a considerable reputation. In 1824 appeared his first important publication, *Histoire de la révolution Française de 1789 à 1814* (2 vols. 8vo., Paris), a work frequently reprinted in France, and translated into the principal European languages. In 1830 he associated himself with Thiers and Armand Carrel in the establishment of the *National* newspaper, and, having cooperated in the overthrow of the Bourbon dynasty, was appointed by Thiers upon his accession to office councillor of state and director of the archives in the ministry of foreign affairs. In 1832 he was elected to the institute as a member of the department of moral and political science, of which in 1837 he became the perpetual secretary; and in the same year he gained admittance to the academy. The only public office which he filled during the reign of Louis Philippe was a mission to Spain on the accession of Isabella II. to the throne. His political views, like those of Thiers, were so distasteful to the government of Lamartine, that in 1848 he was removed from his office of director of the foreign archives and of councillor of state, and has since taken little part in public affairs. The nature of his occupation under Louis Philippe has determined the character of several of his most important works. Among these are a series of documents entitled *Négociations relatives à la succession d'Espagne sous Louis XIV.*, with an introduction (4 vols. 8vo., Paris, 1836-'42), constituting a complete history of the reign of Louis XIV.; *Antoine Peres et Philippe II.* (8vo., 1845); *Vie de Franklin* (1848), one of the best of the minor biographical works published under the auspices of the institute; *Histoire de Marie Stuart* (2 vols. 8vo., 1851); *Charles Quint, son abdication, son séjour et sa mort au monastère de Yuste* (1854), &c. In his capacity of secretary of the section of moral and political science he produced between 1836 and 1843 a number of biographical papers, which were published in the latter year under the title of *Notices et mémoires historiques* (2 vols. 8vo.); and he has also contributed many articles to the *Journal des sciences* and the *Revue des deux mondes*, and other periodicals.

cal. For more than 80 years he has been engaged upon a history of the reformation, in the preparation of which he has collected hundreds of volumes of manuscript correspondence.

MIGUEL, DOM MARIA EVARISTO, a Portuguese prince, born in Lisbon, Oct. 26, 1802. He is the 8d son of John VI. of Portugal, and of Carlotta Joachima, a daughter of Charles IV. of Spain, and spent his early life with his parents in Brazil. His education was so much neglected and his vicious disposition so little checked, that on his return with the royal family to Portugal (1821) he became notorious for his ignorance and brutality. His elder brother Dom Pedro had no sooner accepted the dignity of emperor of Brazil (May, 1822), and his father established a constitutional monarchy in Portugal (October), than Dom Miguel, instigated by his unscrupulous mother, and aided by several of the nobility and clergy and by a large part of the troops, formed plots against the new constitution. His father was for some time a mere puppet in his hands, and, notwithstanding his revolutionary attempts in 1822 and 1828, invested him with the command of the army. Early in 1824 the assassination of the marquis de Loulé, one of the most cherished servants of the crown, took place, and Dom Miguel was generally regarded as a party to this crime. Soon afterward, under the pretence of endeavoring to frustrate conspiracies against his father's life, he caused the ministers and other public officers to be arrested, and the king's throne was only saved by the intervention of the foreign powers. Together with his mother, Dom Miguel was now expelled from the country (May 12). He repaired first to Paris, and afterward to Vienna, where Mr. Hulsemann, the present Austrian ambassador at Washington, became his mentor. His father died in May, 1826, and his sister Isabella Maria officiated for a short time as regent of Portugal in the name of Dom Pedro, emperor of Brazil, who as the eldest son was the legitimate successor to the European and colonial possessions of the house of Braganza. After granting a constitution with an upper and lower chamber (April 28, 1826), Dom Pedro relinquished the throne of Portugal (May 2) to his daughter, Dona Maria (afterward Dona Maria II. da Gloria), then in her 7th year, offering her hand in marriage and the regency during her minority to her uncle Dom Miguel. The latter was officially appointed to the regency, July 8, 1827, and after his arrival in Lisbon immediately assumed the administration, taking the oath to maintain the constitution (Feb. 26, 1828). The absolutists, however, who had made an unsuccessful attempt to overthrow the constitution and to place Dom Miguel upon the throne, soon after the death of his father, now renewed their efforts; and the regent, yielding to his own despotic instincts and to the violent clamors of his mother and her fanatical partisans, assumed the sceptre as absolute king, dissolved the constitutional cortes (March 13), defeated the troops of

the garrisons of Oporto and of other places who declared for Dom Pedro and the charter, convened a new cortes (May 3), and having caused all those legislators who were likely to oppose him to be imprisoned or exiled, he was unanimously declared to be the lawful king (June 21). Dom Pedro's claims to the throne were dismissed under the pretext that as Brazilian emperor he must be regarded as a foreigner in Portugal, and Dom Miguel took formal possession of the throne on July 4. He consolidated his power by the most extravagantly despotic system of government. Those implicated in the Oporto insurrection were severely punished, and an expedition was sent against Madeira and the Azores, whose inhabitants had refused to acknowledge him, and the islands were subdued with the exception of that of Terceira. In the mean while Dona Maria was on her way from Brazil to Portugal; but learning at Gibraltar the changed condition of the country, she refrained from landing at Lisbon and sailed for England, where she was received as queen of Portugal. In 1829 she returned to Brazil, to accompany her father, who had abdicated the Brazilian throne in favor of his infant son, to Europe, and to assert with his assistance her claims upon the throne of Portugal. Dom Miguel's administration was constantly becoming more odious to the people, the gallows being almost as frequently employed as the guillotine during the French revolution. The number of persons imprisoned for political offences was estimated in 1830 at 40,000, beside those who had fled and others who had been banished to Africa. Not content with cruelly persecuting and despoiling his countrymen, he extended his outrages to British and French subjects; and although the fleets of these nations and even of the United States appeared in the Tagus and compelled him to redress the acts of violence committed against the respective subjects of those countries, he persisted in his tyrannical policy; and the position of Portugal, thus jeopardized abroad, was aggravated at home by the disastrous condition of the finances. To meet his necessities, he saddled all Portuguese possessions with new burdens. The island of Terceira, however, refused to comply with his demands; and as the population had from the beginning refused to recognize his authority, a regency was installed there with the duke of Palmella at its head, Dom Pedro issuing thence a decree in favor of his daughter, and collecting there an army, which counted in its ranks soldiers of almost every European nation. The island of St. Michael was captured early in 1832, under the command of Villa Flor, one of the members of the regency; and with an expedition consisting of about 10,000 men, which sailed from that island June 27, Dom Pedro appeared before Oporto July 8, taking possession of the town without the loss of a single man (July 22). Dom Pedro found himself, however, for a long time in great difficulties in Oporto, until 1833, when Napier, the English admiral who commanded his fleet, succeeded in utterly

annihilating that of Dom Miguel in the neighborhood of Cape St. Vincent. The army subsequently advanced upon Lisbon, where the population declared unanimously in favor of Dona Maria. Leiria, an important town between Lisbon and Coimbra, capitulated to the queen's troops in Feb. 1834, and other parts of the country declared rapidly for the constitutional sovereign. The cause of Dom Miguel was desperate. He shut himself up at Santarem, expecting assistance from Spain. The troops sent to Portugal from that kingdom, however, were pursuing another pretender, the English and French governments having formed an alliance for the purpose of supporting the cause of both the queens of Portugal and Spain, and the army sent to Portugal in pursuit of the fugitive Don Carlos actually served to strengthen the forces operating against Dom Miguel. Only a miserable fragment of his followers remained attached to his fortunes; the great body of the Miguelites disbanded, and on May 26 a convention was concluded at Evora Monte, and confirmed by his declaration of May 29, by which he formally consented to leave the country. The terms of the convention were that he should depart within a fortnight, and never again set foot either in Portugal or in Spain, nor in any way concur in disturbing those kingdoms; that he should have a pension of about \$75,000, and be permitted to dispose of his personal property after restoring the crown jewels and other articles; and finally, that he should command the troops still adhering to his cause instantly to lay down their arms, and the fortresses to surrender to Dona Maria. On June 1 he embarked at Sines on an English frigate, and landed at Genoa June 25. His first act there was to protest against the convention of Evora, in consequence of which he forfeited his annuity from the Portuguese government. He has since resided at Rome, where he was recognized as the lawful king of Portugal by the papal authorities. He has also spent several years in London, where he lived in humble lodgings, and where he was noted for his debaucheries and associations with intriguers of all nations. In 1851 he married the German princess Adelheid von Löwenstein Wertheim-Rosenberg, by whom he has a son (Miguel, born in 1853) and 4 daughters, the youngest of whom was born in Nov. 1858.

MILAM, a central co. of Texas, bordered N. E. by the Brazos river, intersected by Little river, and drained by its tributaries the San Gabriel, Bushy creek, and others; area, 850 sq. m.; pop. in 1858, 8,476, of whom 1,128 were slaves. The surface is generally rolling, in some places hilly and broken, and the soil mostly fertile. The productions in 1850 were 38,539 bushels of Indian corn, 8,032 of sweet potatoes, 26,808 lbs. of butter, and 675 of wool. In 1859 the value of land was \$375,847. Capital, Cameron.

MILAN (It. *Milano*; Germ. *Mailand*; anc. *Mediolanum*), the principal city of N. Italy, and

capital of Lombardy and of a province of its own name, situated S. of the Alps, in lat. 45° 28' 10" N., long. 9° 11' 30" E., in a fertile plain between the small streams Lambro and Olona, which connect by the Naviglio Grande canal with the Ticino and by the Martesana canal with the Adda, establishing a communication with the Lago Maggiore, the lake of Como, and the Po; distant 176 m. by railway W. from Venice, and 80 m. in a straight line N. E. from Turin; pop. in 1857, 186,685. Raumer the historian says: "Milan stands in a sea of green trees, as Venice stands in a sea of green waters." Unlike other celebrated Italian cities, Milan combines remarkable natural and architectural attractions with appearances of comfort and material prosperity; and it is justly regarded as one of the most pleasant cities of Europe. Its form is nearly circular. The length of the canal which forms the circumference of the most densely populated part of the city is 5 m.: the whole circuit of the modern city is 8 m., and that of the outer wall 10 m., the latter area comprising, beside the city proper and its suburbs, a great number of gardens and orchards. The principal gates of the city are the Porta Comasina, Nuova, Orientale, Tosa, Vigentina, Ludovica, Romana, Ticinese (by which Bonaparte entered after the battle of Marengo), Vercellina (built to receive Napoleon when he came to assume the iron crown), and Tenaglia, which leads to the Simplon. The principal entrance to the city is through the last named gate, by an esplanade called Piazza di Castello, containing the ancient Gothic castle of the Visconti family. The street running all round outside the city is called Strada di Circonvallazione. Many of the streets are narrow and winding, but they are generally well paved, and some of the thoroughfares are admirable. Many streets parallel to and in the immediate vicinity of the canal retain the name of *terraci* or terraces. The Piazza de la Fontana is the largest square. The Piazza Borromeo is adorned with a statue of that saint. The Piazza di Castello or esplanade was much embellished by Eugène de Beauharnais during his viceroyalty. On the N. E. side of the castle is the Piazza d'Armi, and opening into it is the *arco della pace*, second only to the *arc de l'étoile* in Paris, a magnificent white marble triumphal arch, principally the work of Cagnola, begun in 1807 and completed in 1838, standing beyond the Duomo d'Ossola, on the Simplon road. The most fashionable promenades are the streets called *corsi*, which lead to the principal gates. The corso of the Porta Orientale is the most beautiful and most frequented.—The houses of Milan are generally from 3 to 5 stories high. There are not as many sumptuous mansions as in Genoa, Rome, and Florence, but some of the palaces or *case*, as the Visconti, Belgiojoso, Annone, and Belloni palaces, are fine architectural monuments executed by distinguished artists, and containing many works of art. The archiepiscopal palace, the royal palace (Palazzo della Corte), the Palazzo Marini or of the treasury,

ary, the palace of justice, that of the government, the palace of science and art (Brera), the mint, and the famous *monte di stato* or public loan bank, are among the most remarkable public buildings. They are all eclipsed, however, by the cathedral, next to St. Peter's the largest church in Italy. It is situated almost in the centre of the city, in the Piazza del Duomo. It was begun by Visconti in 1386 on so large a scale that it is not yet quite finished, although Napoleon I. gave a powerful impulse to its completion; and though the main design has been carried out, the details present inconsistencies and anachronisms of style. The interior is crowded with monuments of prelates and princes and relics of saints. The cathedral contains 53 piers, about 100 pinnacles, and upward of 4,400 statues. In fretwork, carving, and statuary, it is said to eclipse all other churches in the world. Eustace in his "Classical Tour" says: "Its double aisles, its clustered pillars, its lofty arches, the lustre of its walls, its numberless niches, all filled with marble figures, give it an appearance novel even in Italy, and singularly majestic." (For its dimensions see CATHEDRAL, vol. iv. p. 578. See also Franchetti, *Storia e descrizione del duomo di Milano*, Milan, 1821; and Rupp and Bramati, *Descrizione storico-critica del duomo di Milano*, Milan, 1823, with plates.) One of the other most remarkable churches is that of St. Ambrose, renowned on account of its high antiquity and as the scene of ecclesiastical councils, political conflicts, and the coronation of sovereigns. In the refectory of the ancient Dominican convent, the present church of Santa Maria della Grazie, is the celebrated fresco of the "Last Supper" by Leonardo da Vinci. The church of Santa Maria, near that of San Celso, in the Borgo San Celso, is noted for its beauty. The church of San Carlo Borromeo, opened in 1847, built after a design of Amati, is surmounted by a dome only second in size to the Pantheon and containing a marble group by Marchesi; but the interior has still an unfinished appearance. Milan abounds with charitable institutions, which possess property to the amount of over \$35,000,000. The principal of them is the great hospital, 880 feet in length by 360 feet in depth, founded by Francesco Sforza in the 15th century, open to all applicants, and containing a free dispensary; among other endowments it has received two legacies respectively of \$600,000 and \$1,800,000, bequeathed by private individuals. Among the other hospitals are the large foundling hospital; the Trivulzi hospital, founded by a nobleman of that name for the relief of the aged; and the lazaretto, the most extensive of them all, situated outside of the walls, founded in the 15th century for the plague-stricken, and consisting of 4 ranges of buildings, nearly 1,200 feet each in length, and enclosing an area of more than 80 acres.—Education is represented in Milan by the archiepiscopal seminary, 2 lyceums, 3 gymnasiums, and a number of colleges and schools, including one for deaf mutes, one for veterinary surgeons, and

one for the technological sciences. There are an institute of science, a geographical-military institute noted for issuing excellent maps, a collection of zoology and palæontology in the *museo municipale di storia naturale*, and other establishments and societies for the promotion of science, literature, and art. The intellectual activity of the city has been rapidly increasing since the overthrow of the Austrian rule in 1859, and is particularly evident in the great number of newspapers and periodicals now published there; one of the most able among the latter is *Il politecnico*, edited by the accomplished Carlo Cattaneo. There are now (1860) probably more books published in Milan than in any other city of Italy. The Milanese school of engravers has acquired a high reputation within the last 20 years. The academy of fine arts (of which D'Azeglio, the Sardinian governor of Milan, was appointed president in Aug. 1860) is one of the most celebrated institutions of its kind in Europe, and the *palazzo delle scienze e delle arti*, in which it is situated (commonly called the Brera from having originally been a Jesuit college called Santa Maria in Brera), is one of the chief ornaments of the city. It contains an extensive gallery of paintings, rich in works by Lombard and Bolognese artists; the public library of nearly 190,000 volumes, including the works bequeathed to it by Haller; a number of medals and an archaeological library; a collection of casts; a botanical garden, and an observatory, one of the best in Italy, under the direction of Carlini. Beside several other special libraries in the Brera, Milan is the seat of the world-renowned Ambrosian library, founded by Cardinal Borromeo, and carefully explored by Cardinal Mai, who made there important discoveries of palimpsests. (See AMBROSIAN LIBRARY.) The most extensive private library in Milan is that of the marquis Trivulzi. The theatres and theatrical entertainments at Milan are numerous and excellent. La Scala vies with San Carlo at Naples, being capable of accommodating between 3,000 and 4,000 persons. Its musical audiences are perhaps the most fastidious in the world. Attached to it is an academy of dancing, and it also contains a *sala di ridotto* for concerts and balls. Among the other principal theatres are the Canobbiano, the *teatro re*, and the *filodrammatico*, conducted exclusively by amateurs, and where Pasta and other distinguished artists first made their début. The amphitheatre, built in Napoleon's time, is capable of containing 80,000 spectators, and is a favorite place for races, fireworks, balloon ascensions, &c. The arena can be filled with water and used for boat races. The city contains fine coffee houses and hotels, elegant shops, and a magnificent bazaar (*galleria di Cristoforo*); and on account of its gay and bustling appearance it has been often called "the little Paris." Milan is the seat of an archbishop, and of the principal civil and military authorities of Lombardy. The fortifications, consisting of a bastioned wall and of some other works, form an

irregular polygon, and are not sufficiently strong to withstand a siege; but the works have been strengthened since 1850. In the inland trade, the commercial activity is greater than that of any other city in Italy. The principal articles of commerce are silk, grain, rice, and cheese. The manufactures of silk goods, ribbons, felt and silk hats, turners' work, cutlery, and porcelain are important.—Ancient Milan or Mediolanum was the chief place of the Insubres in Cisalpine Gaul, and for a long time the capital of that province. It fell into the hands of the Romans about 222 B. C. Under the empire it advanced rapidly in prosperity and in political and intellectual importance, insomuch that it was called the modern Athens and little Rome. It became the central point from which the high roads of N. Italy radiated; its admirable position midway between the Alps and the Padus (Po) made it the natural capital, and it was the actual imperial residence under Maximian and some of his successors, from about the beginning of the 4th till that of the 5th century, when the imperial court was transferred to Ravenna. By his edict issued at Milan (313), Constantine granted tolerance to the Christians. St. Ambrose was upward of 22 years archbishop of Milan, where he died in 397; several of his hymns are still sung in the churches of Milan, and his personal influence made his metropolitan see paramount in the councils of Christendom. In the middle of the 5th century the city was taken and plundered by Attila. It next became the capital of the Gothic kings, and was recovered by Belisarius, but retaken by the Goths (A. D. 539) and almost entirely destroyed and nearly depopulated. In the latter part of that century it was occupied by the Lombards, and in 774 it came into the possession of Charlemagne. A number of his successors assumed either at Milan or at Pavia the iron crown, which is preserved at Monza, near the city. After the coronation of Otho I. at the end of the 10th century Milan formed part of the German empire, and its governors were appointed by the emperors. The city was besieged by Conrad II. in the early part of the 11th century, on account of the attempt of Archbishop Heribert and others against the imperial authority. In the 12th century, when Milan was the most wealthy, populous, and influential city in Lombardy, it became the principal opponent of the German emperors, and was twice besieged by Frederick Barbarossa (from Aug. 6 to Sept. 8, 1158, and again from May 29, 1161, to March 4, 1162); and after the second siege it was almost entirely destroyed. Quickly recovering from the effects of this calamity, it was declared a free city after the victory of the Lombard league at Legnano in 1176; and although pledging itself by the treaty of Constance (1183) to recognize the German emperors as chief feudatories and magistrates, it was permitted to withhold from them for all time the revenues of the immense municipal domains. The efforts of the citizens to liberalize their institutions were thwarted

by the conflict between the Guelphs and Ghibelines, the political influence being divided between the family Della Torre, the representatives of the former, and the Visconti, of the latter party. From 1287 to 1811 the Torre were successful in monopolizing the office of *podesta* or chief magistrate. A rebellion against the emperor Henry VII. brought their rivals the Visconti into power in the latter year. Matteo Visconti and his successors extended the power of Milan over almost all parts of Lombardy, and in 1395 it became the capital of the duchy of Milan. The first duke of Milan was Giovanni Galeazzo Visconti. On the extinction of the male line of the Visconti family (1447) Francesco Sforza, the husband of an illegitimate daughter of the last of the Visconti, secured the duchy for himself and his descendants. The claim of France upon Milan, derived from intermarriage with the Visconti, was taken up by Louis XII. (1499), and more strongly by Francis I., who was opposed by the emperor Charles V.; and the duchy was alternately in the hands of the French and of Sforza until Francis was obliged to relinquish his pretensions by the treaty of Madrid (1526). Francesco Sforza II. having received Milan in fief from Charles V., it reverted to that emperor after the extinction of the male line of the Sforzas (1535); he gave it to his son Philip II., and it remained in the power of Spain for nearly two centuries. From the end of the 14th to that of the 16th century Milan was celebrated for its manufactures of arms and armor; and in 1398 the earl of Derby despatched messengers to Visconti to request a supply of the armor of Milan for his purposed duel with the earl marshal. Milan was equally renowned for the elegance and tastefulness of its finery, and became so noted as a leader of fashions in Europe, that according to Nares and Johnson, the word *mil-liner* meant originally an importer of fashionable articles from Milan. In 1576 the city was desolated by the plague, which gave to the cardinal Borromeo opportunities for the display of his zeal. At the close of the war of succession, the duchy was allotted to Austria (1714), and constituted together with Mantua the Austrian portion of Lombardy. After the invasion of the French in 1796 it became part successively of the Cisalpine republic (1797), of the Italian republic (1802), and of the kingdom of Italy (1805). In 1814 it became a province of Austria and part of the Lombardo-Venetian kingdom. Soon after the French revolution of 1848 Milan became the scene of disturbances; and after the departure of the viceroy, Archduke Reynier, a violent insurrection broke out, in consequence of which Gen. Radetzky, the commander of the citadel, was compelled to evacuate the city, which was occupied by the Piedmontese, and a provisional government was established under the auspices of the latter. After the defeat of Charles Albert at Custoza (July 25) the republicans of Milan came into power and overthrew the provisional government. Soon afterward, however (1848)

18), the city was compelled to submit to Radetzky, who entered it with 50,000 men and declared it in a state of siege until December. The disturbances of March, 1849, and the rising of Feb. 6, 1853, were speedily suppressed. The rule of Austria was brought to a close in 1859 by the French and Sardinian armies; and the Austrian troops evacuated Milan June 5. Napoleon III. and Victor Emanuel made their entry into the city June 8, and by the peace of Villafranca (July 11) Milan and the rest of Lombardy were ceded by Austria to France, to be transferred by the latter to Sardinia.

MILBURN, WILLIAM HENRY, commonly called the blind preacher, an American Methodist clergyman, born in Philadelphia, Sept. 26, 1823, noted for his eloquence in the pulpit and the lecture room. In 1859 he visited England in company with Bishop Simpson and the Rev. Dr. McClintock, and delivered lectures in the principal cities to crowded audiences. His "Ten Years of Preacher Life" was published in 1859, and "The Pioneers and People of the Mississippi Valley" in 1860. For a full sketch of his previous career, see **BLIND**, vol. iii. p. 358.

MILDEW. See **FUNGI**.

MILE (Lat. *mille passuum*, 1,000 paces of 5 feet each), a measure of length or distance. According to the estimates of the length of the Roman foot, the ancient mile must have been 1,614 or 1,618 English yards, while the English statute mile amounts to 1,760 yards or 5,280 feet. The English geographical mile is $\frac{1}{8}$ of a degree of latitude, or 1.1428 m. The distance expressed by the term mile varies in different European countries. The following are the values in some countries, as given in Kelly's "Cambist":

	Yards.	Stat. miles.
Modern Roman mile.....	1,628	0.925
Irish mile.....	2,240	1.273
French league (3 miles).....	4,268	2.423
Spanish judicial league.....	4,635	2.634
German short mile.....	6,859	3.897
Spanish common league.....	7,416	4.214
Prussian mile.....	8,287	4.680
Swiss mile.....	9,158	5.201
German long mile.....	10,126	5.758
Swedish mile.....	11,700	6.648

MILES, JAMES WARLEY, an American scholar, born in Charleston, S. C., about 1819. He was educated at the South Carolina college, took holy orders, and became in early manhood a missionary to the East, where he acquired a knowledge of Hebrew, Turkish, Persian, and other oriental tongues. On his return, he became assistant to the rector of the church of St. Michael's, Charleston, but withdrew from this position to accept the professorship of Greek and history in the Charleston college. His health requiring change of scene, he visited France and Germany, prosecuted his favorite studies of philology and philosophy in Berlin, and on his return after two years' absence became librarian of the Charleston college, his former professorship being still kept vacant for him. He has written graceful and vigorous articles for the "Southern Review," and published an elaborate work entitled "Philosophic

Theology, or Ultimate Grounds of all Religious Belief based on Reason" (Charleston, 1849). He has also written highly esteemed fugitive poems, and has long been engaged upon a work devoted to the highest problems of metaphysics.

MILETUS, an ancient city of Asia Minor, situated in the northern part of Caria, but politically belonging to the Ionian confederacy, of which it was the southernmost member. It stood at the northern extremity of a promontory formed by the Grias range, opposite Priene and the headland of Mycale, and commanding the entrance of the Latmic bay, into which the Mæander flowed. Miletus possessed 4 harbors, protected by a group of islands, the principal of which was Lade. It was divided into an inner and outer town, encircled by a wall, the inner being also called Old Miletus. It is, however, difficult to determine the precise position of the now ruined city, owing to the continued changes produced in the bay and its surroundings by the action of the Mæander, which, bringing down immense masses of soil, has filled up the northern portion of the water basin, and changed Lade and the other islands into parts of the continent. The territory of Miletus extended round the bay as far as the promontory of Mycale on the N. and Cape Posidium on the S. The earliest inhabitants of Miletus were Carians, Lelegea, and Oretans, and it derived its historical name from Miletus, a leader of the latter, being also called Pityusa and Anactoria. It was subsequently settled by Ionians from Greece under the lead of Neleus, the younger son of the last Athenian king, Codrus. It was celebrated as an industrial and commercial city, and in the early portion of Grecian history it was the foremost maritime power, extending its commerce and colonies all over the shores of the Mediterranean, the Propontis, and the Euxine. Among its colonies were Naucratis in the delta of Egypt, Sinope in Paphlagonia, Panticapæum in the Taurian peninsula (Crimea), and Odessus, Olbia, Tomi, and Istropolis, on the N. W. shores of the Euxine. At the same period, when culture and arts among the Greeks had their principal seats on the W. coast of Asia Minor, it also occupied a dignified place among the most enlightened cities of Ionia, being the birthplace of the philosophers Thales and Anaximander, and of the historians Cadmus and Hecataeus. It successfully defended its independence against Alyattes and Sadyattes of Lydia, but succumbed to the last monarch of that kingdom, Croesus; and after his fall it was subdued by the army of the Persian conqueror under Harpagnus. Under Aristagoras, the brother-in-law of its governor Histæus, it revolted with the other Ionian cities against Darius Hystaspes, receiving aid from the Athenians, but was finally subdued and destroyed by the Persians (494 B. C.), the great revolt leading to the first invasion of Greece. Recovering, however, under the later Persian kings, it vainly defended the cause of the last of them against Alexan-

der (334), and suffered a new ruin. Having belonged for about a century to the Seleucids, it was annexed to the territories of Rome after the defeat of Antiochus the Great, and shared the fate of the other cities of the province of Asia, dwindling away under the Byzantine rule, until it was totally destroyed by the Turks.

MILFORD. I. A township and village of Worcester co., Mass., on the Milford branch of the Boston and Worcester railroad, 34 m. S. W. from Boston; pop. in 1855, 7,489. In 1859 it contained 6 churches, a bank, and a high school. In 1855 there were 2 machine establishments and several manufactories. The total value of boots and shoes manufactured in 1855 was \$1,789,815. II. A post borough of Kent co., Del., on Mispillion creek, 21 m. S. S. E. from Dover, and 60 m. S. from Wilmington; pop. in 1850, 2,580. It is, next to Wilmington, the largest town in the state, and contains several churches, 2 banks, and a public library. The Mispillion divides it into North and South Milford.

MILFORD HAVEN, a harbor of Pembroke-shire, Wales, and the deepest, safest, and most commodious in Great Britain, formed by an inlet of St. George's channel, N. W. of the entrance to Bristol channel. Its opening is toward the S., but after penetrating a short distance inland it changes its direction and runs E., branching off into numerous bays, creeks, and roads. It is about 10 m. long and from 1 to 2 m. wide. The tides rise from 28 to 30 feet, and at low water it contains as great an area of deep anchorage as the aggregate of Plymouth, Portland, and Holyhead. Lord Nelson pronounced it one of the finest harbors of the world. Of late years great improvements have been made in it, chiefly by the present proprietor of Milford, the Hon. Robert Fulke Greville, who has constructed at his own cost a pier extending 700 feet into the haven. It is designed to make Milford Haven a great port for transatlantic steamers, for which it is thought to possess many advantages over Southampton; and the British government is now constructing a system of fortifications which will render it one of the strongest seaports in the United Kingdom. A royal dockyard was formerly maintained at the small town of Milford on the N. shore of the haven, but has been removed to Pembroke further up the haven. Milford (pop. in 1851, 2,377) is a modern place engaged chiefly in ship building. It has lately been connected by railway with the South Wales line.

MILFORT, LE CLERC, a French adventurer, who in his youth came to America, travelled through the British colonies, and finally, about the year 1776, visited the Creek nation. Here he attached himself to the Creek chieftain, Alexander McGillivray, whose sister he married. He was made a war chief by the Indians, and performed active service against the whigs of Georgia during the American revolution. He remained with the Creeks for 20 years. In 1796, having lost his wife and his friend and brother-in-law McGillivray, he returned to

France, and was made a general of brigade by Bonaparte. About the same time he published an interesting memoir of his residence among the Creeks (*Séjour dans la nation Creek*). He married again in France, distinguished himself in 1814 by a gallant defence of his own house, in the city of Rheims, against a party of Russians, and died soon afterward.

MILITARY FRONTIER (Germ. *Militär-Grenze*; Hung. *Határőr-vidék*), a long tract of land, forming the S. border of the Hungarian provinces of Austria, and now constituting a separate crown-land of the empire, situated between lat. 44° and 47° N., and long. 14° and 23° E., and bounded N. by Carniola, Croatia, Slavonia, and the Voivodina and Banat, E. by Transylvania and Wallachia, S. by Servia, Bosnia, and Dalmatia, and W. by the Adriatic; area about 18,000 sq. m.; fixed pop. in 1857, 1,065,272. Its breadth varies, being greatest in the W. part, which is traversed by continuations of the Julian Alps, branches of which are the Great and Little Capella ranges, and by the Dinaric Alps, while the easternmost division is crossed by offshoots of the S. E. Carpathians. The middle parts are mostly level, and exceedingly fertile. The highest elevation is that of Mount Klek or Ogulin Head (Germ. *Ogulin-Kopf*) near Zengg on the Adriatic, being about 6,500 feet above the level of the sea. The principal rivers are the Danube, which traverses the country in a S. E. direction between Peterwardein and Semlin, continuing its course E. to the southern frontier as far as Orsova, and receiving the waters of the Theiss, the Bega, and the Temes; the Save, which separates the Military Frontier from Bosnia and Servia, and falls into the Danube between Semlin and the Turkish fortress of Belgrade; and the Krupa and the Unna, affluents of the Save, flowing respectively on the confines of Croatia and Bosnia. There are some mountain lakes in the W. part, and numerous beautiful valleys in various regions. Of mineral waters, the sulphur springs of Mehadia, near the confines of Wallachia, are most celebrated, the place being also famous for picturesqueness of scenery. The climate is very mild in the level country, but severe in the mountains. The principal productions are the various kinds of grain, maize, tobacco, flax, hemp, fruits, and wine; and of minerals, silver, iron, copper, lead, and some gold. The animal kingdom is also well represented. The inhabitants are mostly of Slavic race, Croats, Slavonians, Serbs, &c.; but there are also Wallachs, Magyars, Germans, Greeks, Jews, Clementines (Albanians), and gypsies. The predominant religions are the Greek and the Roman Catholic, the former having its centre at Carlovitz on the Danube, the seat of a patriarch or archbishop; the Protestants, United Greeks, and Jews together form less than 1% of the population. There are few towns, but some of them, as Peterwardein, Carlovitz, Semlin, Pancsova, and Old Orsova, all on the Danube, Zengg, Carlopago, and Brood, in the western part.

vision, and others, are important on account of their situation. The country, the organization of which is peculiar, is divided into two military commanderies, the seats of which are not in the Military Frontier, but in Agram and Temesvár. One embraces the western or Croatian and middle or Slavonian frontier lands, and the other the eastern or that of the Banat. Almost the whole male population, the frontier peasantry, being bound to do military service, they are divided into 14 regiments and one battalion of boatmen (Tchaikists), each occupying a separate district, the latter that of Titel. All landed estates are the common property of the frontier communities, the rural buildings being partly inalienable, and partly individual property. All male peasants above 20 years of age are bound not only to serve in defence of the country, but also in foreign wars, and they thus form one of the principal military resources of the empire. Arms, accoutrements, and ammunition, as well as other necessities during the service, are supplied by the government. In all military respects the frontier population (beside whom there are numerous families subsisting by trade, commerce, and other branches of industry) are subject to the rules and penal code of the Austrian army, and in all others to the civil laws of the empire, the frontier communities having their own communal organizations.—The origin of the military organization of the country, which was created and gradually developed as a barrier against the Turks, is traced back to the beginning of the 15th century. Numerous bodies of Christian emigrants or refugees from Servia, Bosnia, and other Turkish provinces, served to strengthen it especially during the 16th century; but subsequently, the original aim being dropped, the modern organization was introduced by the Austrian government, under several organic laws, those of 1807 and 1850 being the most important. The frontier peasantry has proved its zealous adherence to the rule of Austria in various wars, especially during that of the Hungarian revolution in 1848-'9. For an account of another similar organization see TRANSYLVANIA.

MILITARY SCHOOLS, institutions in which soldiers are instructed or youths educated for the army. Of the former class, the "soldier schools" of Prussia, established in every regiment or battalion, in which the privates are taught the common rudimentary branches, and sometimes singing also, are the most remarkable. There are similar schools in the Austrian, British, and other European armies. Academies of the second class, intended to educate officers, were not unknown in antiquity, and are now an indispensable part of the military system of all great nations. The first military school in France was established by Louis XV. at Vincennes in 1751; it had 500 pupils, all of whom were young noblemen. The famous school of St. Cyr was founded by Bonaparte in 1803, and still retains the principal features of its first organization. It has 300 pupils between 18 and 20

years of age, who after a course of 2 years are sent, some to the *école d'état-major*, others to the cavalry school at Saumur, and the rest to the army as sub-lieutenants of infantry. Even before the 7 years' war the French had an artillery school in every town where a regiment of that arm was garrisoned, and their example has been followed by Saxony, Austria, and Prussia. In the last named kingdom the education of officers is provided for by high schools for each arm in every army division, and by the royal military school at Berlin, founded by Frederic the Great, to which the most deserving young officers are admitted from the line. In Great Britain the royal military college at Sandhurst, which comprises a cadet's college and a staff college, and the royal military academy at Woolwich, designed as an artillery and engineer school, enjoy a high reputation. A military college was also established by the East India company at Addiscombe for the education of cadets for their own army. The United States military academy at West Point, founded in 1802, ranks second to no institution of the kind in the world. Cadets are admitted on the recommendation of members of congress and the president of the United States, the number being limited to 250. The education and subsistence are gratuitous, which is not the case at Sandhurst, Woolwich, St. Cyr, &c.; but the graduates are expected to spend 8 years in the public service unless sooner excused. The course of study has lately been raised from 4 years to 5.

MILITIA (Lat. *miles*, a soldier), a body of armed citizens trained to military duty, who may be called out in certain cases, but may not be kept on service, like standing armies, in time of peace. It differs from the *levée en masse* in having a regular organization at all times. Something equivalent to a militia seems to have existed in England in the time of the Saxons. The *ceorles* or peasants held their lands on condition of military service, every 5 hides of ground in most counties being charged with the equipment of one man, and were banded in bodies or companies, the command of which was given to the ealdormen elected by the people in the folk-motes. The peasants were enrolled under the banners of their immediate lords, but in case of rebellion or invasion the state had a paramount claim upon their services, and the lords had no further authority over them than the privilege of leading them in battle. The period of service was limited generally to 40 or 60 days. The organization of this species of militia has been attributed to Alfred, but it seems certain that a national force called the *fyrð*, regulated probably by similar principles, existed before his time. Under the Normans the *fyrð* continued to be maintained simultaneously with the feudal armies, and ultimately became the source both of the modern British militia and of the sheriff's *posse comitatus*. It was not until the reign of Edward III. that a statute was passed providing that no militiaman should be sent out of his

own county except in case of invasion or other grave danger to the realm, nor out of the kingdom in any case. In the 5th year of Henry IV. a law was enacted empowering the king's "commissioners of array" to array and train all men-at-arms, to cause all able-bodied men to arm themselves according to their substance, to amerce those unable to bear arms, and to require the services of persons so armed at the sea shore or elsewhere in season of danger. The command of the militia was often given to the persons charged with these commissions of array, but more frequently it rested with the sheriffs or high constables, each in his own county. Such was the organization of the militia when the parliament of Charles I. in 1642 passed a bill vesting the control of this force, as well as the command of all the forts, castles, and garrisons, in certain commissioners in whom they could confide. The king refused his assent to the bill; and when the parliament thereupon declared the kingdom in danger and issued orders to muster the militia, he issued commissions of array to some of the nobility for the same purpose. Thus began the civil war. After the restoration, the peculiar state of things which had sprung from feudal tenures no longer existed, and the militia was reorganized mainly on its present basis. The king was acknowledged as its sole supreme commander, and no other army was recognized by the law. Lords lieutenant of counties were charged with raising the force, as they had been indeed since the time of Queen Mary; every man who possessed a landed estate of £500 a year, or personal property to the amount of £6,000, was bound to provide, equip, and pay one horseman; every man whose property was $\frac{1}{16}$ of either of those amounts was charged with one pikeman or musketeer; and smaller proprietors united to furnish a soldier, each contributing according to his means. It was not however until 1757, when a bill to reconstruct the militia was passed, that the force acquired much vitality. Amendments have been made from time to time since then; and in 1802 the militias of England and Scotland were consolidated, and that of Ireland offered its services in England in 1804. The militias of Great Britain are now constituted as follows: In each parish lists are prepared every year of all the male inhabitants between the ages of 18 and 35. From these a certain number of men to be enrolled are chosen by ballot, the names of those persons who are exempt being first stricken off. Among the latter are peers, members of other forces, Protestant clergymen, articled clerks, apprentices, parish schoolmasters, resident members of the universities, seafaring men, any poor man with more than one child born in wedlock in England, any man with more than 2 lawful children and less than £50 of property in Scotland, and any man with more than 3 lawful children who pays less than £5 a year of rent and has less than £10 of property in Ireland. With the consent of a majority of the inhabitants the parish may pro-

cure substitutes for the balloted men by voluntary enlistment, offering a bounty of £6 per man, to be paid by a tax on the inhabitants. The time of service is fixed at 5 years. The command of the militia is vested in the lord lieutenant of the county and the deputies whom he appoints, subject to the royal approval. A property qualification is required of the higher officers, ranging from £200 a year for a captaincy to £600 for a colonelcy. Officers and men receive pay while on active service at the same rate as the regular infantry. The mutiny act and articles of war apply to the militia when called out, except so far as they affect life, and there are special provisions for cases of desertion. By the act of 1854 the sovereign is empowered to call out the militia whenever a state of war exists between her majesty and any foreign power; but the old principle that the militia cannot be compelled to serve out of the realm is still adhered to, and special laws have been thought necessary to enable them to volunteer for foreign service. The sovereign may also call out the militia in cases of invasion, rebellion, or insurrection, or imminent danger thereof, the occasion of doing so being first communicated to parliament, or, if parliament be not in session, declared in council and notified by proclamation. When called out for service, the regiments are said to be embodied; they are occasionally embodied in time of peace, when a whole regiment volunteers to do garrison or other duty. The militia is disembodied when it is only liable to be called out for periodical training and exercise. The expensive and complicated system of the ballot, though still existing by law, has been virtually out of use since 1829, parliament annually suspending its operation, and only the skeleton or staff of each regiment being kept up. When it was found advisable to embody the militia during the late Russian war, the men were raised by voluntary enlistment; and such is now the plan generally pursued, the ballot being retained as a last resort when the voluntary system fails. The Indian mutiny of 1857, and the state of European affairs in 1859-'60, gave fresh occasions for putting the plan into operation. The number of men whom the queen is empowered to raise in this way is 80,000 in England, 10,000 in Scotland, and 30,000 in Ireland. Of late, however, Great Britain has relied for defence mainly upon regiments of volunteers, entirely independent of the militia, subject in peace to the control of the home secretary, and in time of war or public danger to the commander-in-chief. They consist chiefly of the recently organized volunteer rifle corps, with 15,000 yeomanry cavalry. A recent official estimate of the citizen soldiery of Great Britain gives the following figures: embodied militia, 15,911; disembodied militia, 52,899; yeomanry cavalry, 15,000; volunteer rifles and artillery, 122,867; enrolled pensioners, 15,000; total, 221,777. Of these, however, not more than 62,000 have been known to be

under arms at any time, including 18,800 volunteers reviewed at Hyde park in June, 1860, and 20,522 at Edinburgh in August; and it is doubtful how far the above estimate can be trusted. Beside the regular militia, a "supplementary" force may be raised whenever the necessities of the state require it, and in 1808 "local" militias were enrolled in various places for the purpose of replacing corps of volunteers. These bodies may be marched to any part of the kingdom in case of invasion or rebellion.—For militia in France, see *GUARDS, NATIONAL*.—In Prussia a system was founded about the beginning of the present century under the name of the *Waffenpflicht*, that is, the obligation of all to bear arms. The whole nation was bound to rise at the call of the king; and in order to secure efficiency in case of emergency, as great a number as possible of young men were compelled to serve as soldiers for a certain time, and then dismissed to their homes until they were required to fight. At the peace of 1814 this system was modified by the creation of the *Landwehr* ("defence of the country"), which is now the principal military strength of the nation. Every Prussian, with the single exception of mediatized princes, is obliged to serve in the standing army from his 20th to his 24th year, half the time on the reserve. Between the ages of 24 and 35 he belongs to the landwehr of the 1st class, and beside frequent drills is called out for 3 weeks annually to exercise in great manoeuvres. In time of war this corps is joined to the regular army, each regiment having a corresponding regiment in the line with which it forms a brigade. The 2d class of the landwehr is composed of men above 35, and is never called out except in time of war when its services are needed for the defence of the country; it is then required to furnish 12,500 cavalry and about 98,000 infantry. The strength of the 1st class, not including officers, is: infantry, 93,000; cavalry, 16,000; total, 109,000. The Austrian landwehr was organized on similar principles with the Prussian, and recruits for the regular army were frequently drafted from it. In 1809 it amounted to 300,000 men, but of late years the government has relied wholly on forced conscription. The Swiss army consists entirely of militia, and is divided into 3 classes: 1, the regular army, composed of men between 20 and 38 years of age, to the number of 3 per cent. of the population; 2, the reserve, consisting of men between 38 and 40 who have served their time in the regular corps, to the number of 1½ per cent. of the population; 3, the landwehr, comprising all men under 44 years of age who are fit to bear arms and are not serving in either of the other divisions. The strength of the army in March, 1860, was as follows: regular force, about 90,000; reserve, 51,000; landwehr, 48,000; total, 184,000. Probably over 100,000 could be brought into the field at a few days' notice. The organization is very complete, and for celerity of movement and concentration the Swiss army will

compare favorably with any in the world. The Russians have a militia, but there is no general fixed system of enrollment, and in some parts of the empire the whole male population is liable to be summoned to arms. Several militia regiments took part in the Crimean war, and proved very effective soldiers. Spain has a militia of about 550,000 men.—Various other states, such as Sweden and some of the smaller German powers, have also devoted more or less attention to this system of national defence; but it has received its fullest development in the United States of America, where it was established in 1792 by an act of congress providing that all able-bodied white male citizens between the ages of 18 and 45, except officers of government, members of congress, mariners in service, and certain others, shall be enrolled and arranged in brigades, regiments, companies, &c., according to the regulations of the legislatures of the different states. They were to furnish themselves with muskets, ball cartridges, &c., at their own expense, but the general government was to provide ordnance and field artillery. Every division was to have at least one troop of horse and one company of artillery, to be raised by voluntary enlistment from the militia at large. Various alterations have been made in the general law from time to time, but its fundamental provisions, requiring the appearance under arms at specified times of all citizens between certain ages, remain unchanged. In each state, all free, able-bodied, white male citizens of the United States between the ages of 18 and 45, constitute the ununiformed militia of the state. In most states, citizenship in the particular state is also a pre-requisite. In Florida, all persons are liable to be drafted, who have "resided in the same 4 weeks in time of peace, and 10 days in time of war." In Arkansas, this residence in the state is stated at two months. The same time is fixed in Louisiana. In Indiana, all the free, able-bodied male citizens, "except negroes, mulattoes, and Indians," form the militia. In South Carolina, aliens or transient persons, between the ages of 18 and 45, are liable, like citizens of that state, to do all patrol and militia duty which the proper officer may require. The power of regulating the patrol is devolved, by the same act, upon the municipal police of the towns and villages. In Michigan, the governor was specially authorized by the resolve of 1839 to form companies of volunteer militia from the half-breeds and Indians. The enrollment is generally made annually by the assessors of taxes. Many sorts of persons are absolutely exempted from militia duty by statute, and many others are conditionally exempt. The statute provisions vary somewhat, but, taking them all together, we shall find exempted the vice-president of the United States, U. S. officers, judicial and executive, members of congress and of state legislatures while in session, judges and clerks of courts, certain specified state officers, postmasters, mail carriers, custom house

officers, ferrymen, inspectors of exports, superintendents or employees in state hospitals, almshouses, and prisons, keepers of lighthouses, members of fire companies, regular physicians and surgeons, clergymen, faculties and students of colleges and academies, pilots, mariners in service, military or naval officers who have been regularly discharged after a specified service, persons scrupulous of bearing arms, or unable to do so from certified bodily infirmity, idiots, common drunkards, lunatics, vagabonds, paupers, and persons convicted of infamous crimes. Many of the preceding classes, however, are only exempted by the payment of a small annual tax, never over \$5. Many states specially exempt Shakers or Quakers, and in New Hampshire the form of the elder's certificate of membership is given. In New Jersey, minors are exempt in time of peace. In Arkansas and North Carolina public millers, and in North Carolina lock-keepers on the Dismal Swamp, are exempted.—The ununiformed militia are, in general, subject to no military duty whatever, except in case of insurrection, war, invasion, or to prevent invasion. In most parts of the Union, however, it has been found that the periodical trainings, though burdensome to a great majority of the people, are too infrequent to be of much use; while the unmilitary appearance of the ranks and the absence of music, uniform, accoutrements, and other incidentals which contribute so much to martial éclat, have too generally drawn ridicule upon them. Hence in many of the states, as in England, compulsory enrollment has gradually given place to the volunteer system. The volunteer regiments are limited in some states to a specific number—in Maine, for instance, to 4,000—and are always first to be called into service. Such is the provision in Massachusetts. Usually, each man is required to furnish his personal arms and equipment, while the general armories, ammunitions, ordnance, musicians, &c., are provided by the state, upon the officers giving bonds and securities for proper care of the same. In Ohio, the militia of the state were formerly supplied with arms from the United States. By the bill of rights of this state, "the military shall be in strict subordination to the civil power." The statutes also authorize the governor, who is commander-in-chief, to determine the fashion of the infantry uniform. In Rhode Island the companies of militia are all chartered, and may admit members to the number of 500 each. In Maine no company can be created by the governor of less than 48 men, but in Alabama the colonels commandant have power, by the act of 1825, to form companies in their respective regiments of "a less number than 40 privates," but not less than 30. In Louisiana, the militia in each parish of the state constitute one regiment. Sometimes a provision is found that officers and soldiers once enlisted shall do duty for a term of years, which in New York is 7, unless disability absolutely prevent, or they be discharged regularly. Fines are imposed for

non-appearance on the statute days for military duty, for want of uniform, for deficiency of arms, for disobedience, for parading with loaded muskets, and the like. In New Hampshire a fine of \$2 is imposed on officers "for treating at trainings." A common penalty for non-appearance at trainings is \$2. The statutes often, as in the New England states, provide for the collection of fines by distress, and prescribe a warrant therefor. They also detail the excuses for absence that are valid, and make a surgeon's certificate of sickness important or essential; and they determine the period within which the said excuses are presentable. In 1816 an act was passed in Delaware remitting all military fines for non-attendance on parade days. The statutes furthermore provide, in general, for the pay and rations of the militia, the common sum received by each soldier annually being \$1. In Vermont he is likewise exempted from certain state taxes. Ordinarily neither officers nor soldiers can be arrested on civil process (though they may be on criminal) while going to, or returning from, or performing, any military duty, or any election of officers. Certain aides-de-camp, adjutants, and the brigade inspectors and clerks are allowed a salary by statute. Many of the volunteers are remarkable for precision of drill, general excellence of appointment, and *esprit du corps*, and apparently lack none of the essentials of good soldiers. The governor is always the commander-in-chief in time of peace, but in time of war his functions are different in different states. He appoints his own staff, and issues commissions to all militia officers, who are chosen in various ways. In New York and Massachusetts, captains and lieutenants are elected by the privates of their respective companies, field officers by the company officers, and general officers by the field officers, except the major-general, who is nominated by the governor in New York and by the legislature in Massachusetts. In New Hampshire general and field officers are appointed by the governor and council, and captains and subalterns are nominated by field officers and appointed by the governor. In Vermont, the privates elect their company officers, and the captains and subalterns nominate the field officers, who appoint their staff. In some of the other states the officers or a certain number of them are elected by all the citizens subject to military duty.—In time of rebellion, insurrection, or invasion, the president of the United States has power to call out the militia of such states as he may deem expedient, and to keep them under arms 6 months; but the call must be made through the several governors, who are to judge whether it is justified by the condition of affairs, and may refuse to sanction it if they think proper. In case of riot, the governor may order out the militia to support the laws, and a penalty is laid upon officers and soldiers refusing to obey such orders, but they are usually allowed a compensation when so called out. In Massachusetts, the form of requir-

sition for ordering out troops in case of riot is laid down by statute. In Louisiana, the mayors of towns may demand a detachment of militia in case of "conflagration, or other public exigency," to preserve order and protect property. In North Carolina, three justices may order out the militia to suppress outlawed or runaway negroes. In Connecticut, the captain-general, or, in his absence, the major-general, may on alarm or invasion order out the militia. In Missouri, the military are required to render prompt obedience to the officer summoning them to quell a riot, under penalty of \$50. In Virginia, the term of service of militia called out by state authority is 6 months. In Kentucky, no militiaman is compelled to serve more than 120 days in succession; a tour of duty is estimated at 30 days from the rendezvous. In some states no parade of troops is allowed under severe penalties on days of national, state, or town elections. In New York, no parade of the militia can be ordered, under penalty of \$500, on any day during which a general or special election shall be held, nor within 5 days previous to such election, except in case of insurrection, or invasion, or imminent danger. A similar provision is adopted in Wisconsin. In Maine, all parades are forbidden within 50 rods of a court house while a court is there in session. The statutes generally provide for two or more days of parade and training. In the northern states, one of these is fixed in May or June, "the May training" being familiar to all dwellers in New England. In some of the southern states this spring parade comes rather earlier. Authority is also commonly given by statute for encampments or musters, to be held in the late summer or in autumn. But sufficient warning must be given of encampments, and also of any inspection or training; and a time for suggesting excuses for absence is prescribed, and also the manner in which the sergeant shall make his return of the warning given. In drafts for actual service, the person must appear, procure a substitute, or pay the statute penalty. The militia in actual service are put under the rules provided by the U. S. laws, and the discipline, pay, and rations are those of the regular U. S. troops; but they are always to be led by their own officers. Among the rules imposed by some statutes upon militia in actual service, are, that they shall diligently attend divine service, and behave decently thereat, and shall use nowhere any profane oath or execration, a commissioned officer in Maine paying for each offence 67 cents. If a soldier or officer is killed in service, his family will be relieved by the state. In Maryland, officers and privates disabled in service are entitled to half pay. All the statutes provide for courts martial, and regulate their organization, powers, duties, and limits. It is provided that all officers arrested shall have a copy of their accusations; that all the members of the court shall take an oath, the form of which is usually given; that the records of proceedings shall be

faithfully kept. The votes of two thirds are usually required for a sentence of death; and those accused of crimes punishable by the known laws of the land are generally to be surrendered to the civil authorities. In most states courts of inquiry, for ordinary questions of military discipline, are established. In the district of Columbia, the president of the United States has in general the powers of governors in the states over the militia.—We subjoin a table of the number of the militia in the several states, according to the latest returns received at the office of the adjutant-general of the United States:

States and Territories.	Date of last return.	No. of Militia.
Maine.....	1856	73,503
New Hampshire.....	1854	33,503
Vermont.....	1843	23,915
Massachusetts.....	1850	157,803
Rhode Island.....	1853	16,711
Connecticut.....	1853	51,005
New York.....	1856	337,325
New Jersey.....	1853	81,934
Pennsylvania.....	1853	350,000
Delaware.....	1837	9,230
Maryland.....	1833	46,364
Virginia.....	1853	150,000
North Carolina.....	1845	73,443
South Carolina.....	1853	36,072
Georgia.....	1850	73,000
Florida.....	1845	12,123
Alabama.....	1851	76,603
Mississippi.....	1833	36,034
Louisiana.....	1850	91,334
Texas.....	1847	12,703
Arkansas.....	1850	47,750
Tennessee.....	1840	71,303
Kentucky.....	1853	66,970
Ohio.....	1853	272,300
Michigan.....	1854	97,004
Indiana.....	1833	53,913
Illinois.....	1855	257,420
Missouri.....	1853	113,047
Wisconsin.....	1855	51,331
Minnesota.....	1850	23,973
California.....	1857	207,730
Utah.....	1853	2,321
District of Columbia.....	1853	2,301
Total.....	3,070,937

There are no returns from Iowa, Oregon, Washington territory, Nebraska, Kansas, or New Mexico; and making allowance for this, and for the fact that many states which are increasing rapidly in population have made no reports for several years, we may safely estimate the militia of the United States at 4,000,000.

MILK, a white fluid secreted in the glands of female mammals, and furnished by them for the nourishment of their young. It contains within itself all the elements required for the sustenance and growth of the human body; and as that of different animals is essentially the same, the milk of many of the larger mammalia, as of the cow, the goat, the camel, the ass, ewe, and mare, has from time immemorial been made use of as an article of human diet. The taste of milk is bland and sweetish; it has a faint odor, an alkaline reaction when pure, and an opacity and whiteness due to myriads of little globules of fatty matter distributed through it (see BUTTER, and CREAM); its specific gravity, which varies according to its composi-

tion and other conditions, ranges in general from 1.025 to 1.081. The globules are of various sizes, and when milk is examined by the microscope they are seen to be quite distinct from the watery fluid in which they are suspended. If the milk is treated with dilute acetic acid, each one of these globules is seen to be included in a very thin investing membrane. They constitute the chief portion of the cream, and according to their abundance give richness to the milk. Being of less specific gravity than the fluid, they rise and gradually collect at the top, forming the layer of cream. When separated, the remaining portion is left of greater specific gravity; and hence it is seen that great density alone is no indication of good quality in milk. If the globules are few and of small size, and the milk does not appear homogeneous, and by the addition of ammonia becomes viscid, it is of poor and may be of unhealthy quality. The fluid portion of milk is water containing dissolved in it caseine or cheese, sugar of milk, and various salts. By causing the proportions of these to vary in a specimen of milk, this is made to undergo a variety of modifications. Thus cream consists of the fatty particles with a small proportion of sugar, caseine, and the other constituents of milk. When removed it leaves behind the skim-milk, containing little fat, but nearly all the cheese, sugar, and salts. Buttermilk, which is the residue after the buttery particles are removed by the process of churning, contains less fat than skim-milk, the buttery particles being mostly brought together in the process of churning by the mechanical action and consolidated in one mass. Both skim-milk and buttermilk, however, are nutritious articles of diet from the amount of nitrogenous matter they contain. Cheese is the caseine precipitated by rennet and compressed in moulds. When made from whole milk, it contains a larger portion of the buttery particles than when made from skim-milk. Before the curdy precipitate is separated, the mixture is known as curds and whey; the former is the mixed caseine and butter, and the latter, called also the *serum*, consists of the water of the milk, the sugar, and the salts. When the fluid portion is partially pressed out, the remainder is cream cheese.—In comparing together milk of the same animal under different conditions of age, health, food, length of time after parturition, &c., as remarkable differences in the proportions of the ingredients will be observed as when samples of the average milk of a number of different species of mammalia are compared. The following table exhibits the composition of several kinds of milk, the first column presenting the average result of 10 analyses by Prof. Poggiale, the next 4 being furnished by Messrs. Henri and Chevalier in the *Journal de pharmacie*, vol. xxv., and the last by Dr. Samuel R. Percy of New York, as the composition of the milk of a healthy woman. The albumen in these analyses is reckoned with the caseine.

Constituents.	Cow.	Ass.	Goat.	Ewe.	Woman.	Woman.

Of these constituents the most uniform in its proportions is the sugar, but this may be materially increased by the use of saccharine food, as is found in feeding cows upon carrots and beets. The sugar of milk is crystallizable, but it is less sweet and less soluble in water than cane sugar. The butter is composed of a solid and liquid fats and glycerine. Its proportion is very variable. (See BUTTER.) When milk is decomposed, lactic acid is generated, which combines with some of the bases of the salts. As these exist in the ashes obtained from cow's milk, they are thus enumerated by Schwartz in the order of their relative proportions: phosphate of lime, chloride of potassium, phosphate of soda, phosphate of magnesia, soda (combined in the milk with lactic acid), phosphate of iron. Simple methods of separating the constituents of milk are given in many of the works on organic chemistry. MM. Vernois and Becquerel adopted the following mode in their analyses of the milk of the principal breeds of cows, mares, sheep, and the Hungarian buffalo, present at the exhibition of 1856 at Paris; a report of which examination was published in the *Annales d'hygiène publique*, vol. vii., 11th series, p. 271. See also the same work for further memoirs on this subject, vol. xlv., 1st series, 1853, p. 257, and vol. iv., p. 43. The milk to be analyzed is divided into 8 portions. The first of these is evaporated to dryness by being left in a warm oven 24 hours protected from the air. The residue gives the solid parts, the loss the water. From the solid parts the butter is taken up by ether, and being separated by filtering, the loss of weight represents the quantity of butter, or this is obtained directly by evaporating the ether from the filtrate and weighing the residue. The solid parts, being burned in a platinum capsule, give the weight of the salts by incineration. To the second portion a few drops of acetic acid and a little rennet are added, and the liquid is boiled. It coagulates, the albumen and caseine separating from the serum, which contains the sugar and some soluble salts. After filtering, a little acetate of lead is added to the serum, which causes the precipitation of part of the extractive matters; and the liquid is then introduced into an instrument called the polarimeter, by which the quantity of sugar in the solution is determined by the deviation of the plane of polarization. According to the authors the result may be depended upon as mathematically exact. The third portion is employed to give the proportion of albumen. It is left to coagulate naturally for 24 hours, and is then gently shaken, so as to mix the parts uniformly, and filtered. Caseine remains in the filter, and albumen, sugar, and

the salts pass through. Any caseine that escaped coagulation may be made to separate by adding a little rennet to the serum. The albumen is then made to precipitate either by ebullition or the addition of alcohol, and after being separated and dried is weighed. The weight of the caseine and extractives is calculated by deducting from the total weight of the solid parts the sum of those already obtained for the butter, sugar, salts by incineration, and the albumen. Other methods less exact than this are given in Dr. Hassall's "Adulterations Detected." The quantity of sugar may be approximately ascertained by evaporating the whey to dryness, weighing the residue, and deducting the weight of the ash left in its incineration. Milk from unhealthy animals often exhibits an increased proportion of phosphate of lime in the ash. When milk is exposed to a warm temperature it ferments, and lactic acid is generated, which has the same ultimate composition as sugar of milk. Under certain conditions the vinous fermentation may now take place, the sugar of milk be converted into grape sugar, and a spirituous liquor be produced, as is practised by the Tartars. (See Kourmiss.) Various circumstances affect the quality and composition of milk. That called colostrum, given by the cow immediately after calving, is yellowish, thick, and stringy; for several days it is unfit for use. Examined by the microscope, it is seen to contain numerous corpuscles of large size and granular appearance. Milk drawn from the cow in the morning is thought to be of better quality than that of the afternoon; and a remarkable difference is perceived in the proportion of cream in the first and last portions of the milking, the latter containing twice as much cream as the same quantity of milk of the former. In the udder of the cow the cream seems to rise as it does when the milk is collected in a vessel, and that last drawn thus brings with it the most cream.—MM. Vernois and Becquerel in their researches, before referred to, found a great difference in the character of the milk of cows from different regions, some being especially suitable for butter and other for cheese. The quantity of food furnished to cows seemed to have a notable influence upon the quantity of milk, and especially upon the production of sugar and caseine; while a moderate supply of food seemed to be more favorable for the production of butter and albumen. The milk of the goat was peculiar in containing a very large proportion of albumen, averaging 18 parts in 1,000, the nearest approach to which was the milk of Durham cows, which contained 11 parts in 1,000, and others various lower proportions down to 3 parts in the milk of Swiss cows. The milk of the buffalo of Hungary was also peculiar in this respect, and also for its large proportion of butter qualities, which induced them to recommend the introduction of the breed into France. The milk gave the following quantities in 1,000 parts: water 806.40; soluble parts 193.60, viz.:

sugar 45.18, butter 84.50, caseine 42.47, albumen 18.00, salts 8.45. The largest proportion of butter obtained was from the Angus breed of cows, which gave 98.80 parts in 1,000; and of caseine from the cows of Paris, which gave 55.15 parts, including in this about 4 parts of albumen.—Some of the methods of testing the quality of milk are noticed under GALACTOMETER. By this the specific gravity is ascertained both of the whole milk and skimmed milk; but as these data are of little value without a knowledge of the proportion of cream, another instrument, invented by Sir Joseph Banks, and called the lactometer, is used in connection with the galactometer. It is a tube about $\frac{1}{2}$ inch in diameter, and 10 inches of its length graduated in tenths of an inch. When filled with milk, the tube is set aside for 12 hours for the cream to rise. The proportion of this is then read off in the number of divisions occupied by the upper stratum. The thickness of this stratum is very variable with different sorts of genuine milk; but its general range is from 9 to 14 of the divisions, indicating as many percentages. Dr. Hassall thinks the average of pure milk does not exceed $9\frac{1}{2}$ of cream. Dr. Normandy rates it at 8 to $8\frac{1}{2}$. A writer upon this subject in Boston, Mass., estimates that the milk delivered there by honest milk dealers will rarely yield over 8 per cent. of cream; while in Baltimore, where he received it in his own cans, brought only 4 miles and upon a light spring wagon, the proportion of cream was often 14 per cent., and never below 10. When carried far by railroad or in wagons without springs, a portion of the cream is apt to be converted into butter and sink to the bottom of the cans, from which it is not taken out in the ordinary manner of supplying customers. The proportion of cream is also determined by an instrument, invented by M. Donné of Paris, called the lactoscope, the principle of which is based upon the opacity of the fluid caused by the buttery particles. A few drops of the milk are introduced between two plates of glass, so set in an ocular tube, that they can be brought close together or separated by means of a graduated screw, and thus enclose at their base a thinner or thicker stratum of milk. The observer then looks through the tube at a light set 3 feet off, and gradually separates the plates of glass, increasing the depth of the layer of milk, till this at last becomes so opaque that the light is lost to view. The figure to which an index on the instrument then points refers to a table, upon which the corresponding quality of the milk as to quantity of cream is designated. The lactometer and lactoscope determine only this one point, and if alone depended upon might lead to very erroneous conclusions as to the general quality of milk. The normal proportion of cream might, for instance, be found in milk to which a considerable quantity of water had been added; and to determine the presence of this it would be necessary to take also the specific

gravity of the skimmed milk.—Of all articles of food used by man, milk is the most important. In his infancy it is his sole support, and in after life it is employed in a variety of forms for his daily nourishment. It is well understood that the health of the child is materially influenced by that of the parent or nurse who supplies this food; and all thoughtful and intelligent parents are scrupulously careful to procure it from pure and wholesome sources. Even the quality of the food of the nurse is an object of solicitude; and when the milk of the cow is substituted for the natural food, care is taken that it should be from a healthy animal, and even from the same one for the same child. But such precautions unfortunately are beyond the reach of the multitudes of the poor, of large cities especially; and their offspring are too often supported by the milk of sickly mothers, or unwholesome milk furnished by the dealers. By reason of its complex composition milk can be tampered with in a great variety of ways, and cheap materials can be substituted for the natural ingredients, seriously affecting its quality, while the fraud can be detected only by the skilful examination of the chemist. The nourishing cream is removed

and water is substituted. This involves the addition of white thickening substances to disguise the cheat, and of other strange ingredients to restore or retain the sweetness and saltiness of the milk. Large cities are almost hopelessly exposed to these frauds; but worse than all, a large portion of the milk with which they are supplied is that of diseased cows kept in crowded stables and fed with cheap unwholesome food. The evil has become so serious that in New York the attention of medical men has been long directed to the subject; and in 1859 a careful investigation was made into the character and properties of the milk of cows fed upon the swill of distilleries, the results of which were embodied in a report of Dr. R. Percy, M.D., and published in the "Transactions of the New York Academy of Medicine," vol. ii. part iv. In this are presented representations of various sorts of milk, as they appear highly magnified. From these it is evident that the microscope in skilful hands may be depended upon to afford excellent indications of the comparative qualities of milk. But other tests also were employed, and numerous careful analyses were made of the various sorts of milk, many of which are given in the following table.

Constituents.	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.	13.	14.	15.	16.

No. 1 is the milk of a cow kept for family use in New York; No. 2, of swill-fed cows from distillery stables in New York; both the analyses are by Dr. Doremus. The following are by Dr. Percy: No. 3, country milk furnished by a dealer to customers in New York; No. 4, the same by another dealer; No. 5, milk from Farmington, Conn., a mixture of that of 6 cows; No. 6, milk as drawn from the cows in Williamsburg distillery stable; No. 7, sample of same delivered to customers; No. 8, another sample of the same as sold to customers; No. 9, milk as drawn from the cows in one of the New York distillery stables; No. 10, milk from the same source as delivered to customers; No. 11, milk from a sick cow, Williamsburg distillery stables; No. 12, sample of the milk used by Gail Borden for preparing the "condensed milk;" No. 13, condensed milk as prepared from No. 12; No. 14, cream from the same milk (No. 12); No. 15, cream from No. 5; No. 16, cream from milk of distillery cows at Brooklyn. Healthy milk was observed by Dr. Percy to have an alkaline reaction, while that of diseased animals was always acid. The same observation had been made by Gay-Lussac, Berzelius, and others; and the effect is found to be induced in a short time in animals shut out from the light of day, and in those confined in bad air and supplied with bad food. In this table the bad milk is at once recognized

by its unduly large proportion of caseine, while the sugar and often the butter is as disproportionately small. The large amount of saline matter found in the bad milk is caused by the addition of salt made for the purpose of disguising the adulteration with water. But the proportions of the ingredients, though sufficient to expose the character of the milk, cannot indicate the poisonous qualities of the worst sorts, or the evil effects that may follow their use. In organic compounds, such as we use for food, as in the air we breathe, the most dangerous poisons may lie concealed beyond the power of detection of the most delicate tests or the most powerful microscopes, and their existence is brought to light only by their effects upon the human system. Thus the real nature of the distillery milk is most properly shown in the report by citation of several cases of disease in young children traced directly to its use.—The preservation of milk from putrefaction is an object of no little importance, and several processes have been devised for this purpose. In France this is accomplished by causing the portion of the milk to combine with other matters, and thus separate in a solid form from the aqueous portion; but the compound is not properly milk. It is also evaporated down to the consistency of sirup, and then by the addition of sugar made into a solid compound of milk and sugar; and by a third method it is pre-

erved by expelling the air from it, and hermetically sealing the bottles while they are under steam heat of about 100°C . In this way milk has been preserved perfectly fresh for $5\frac{1}{2}$ years. In the United States a patent was granted in 1856 to Gail Borden, jr., for another method, which he has since successfully conducted in Wethersfield co., Conn., supplying what is called "condensed milk" to many consumers in New York. By his process the milk when drawn from the cow is immediately cooled in order to check its changing. It is soon after rapidly heated to 170° to 190°F ., and is then removed to vacuum pans in which evaporation of the water is effected at a temperature not exceeding 180° . When sufficiently concentrated, the pans are quickly cooled down by passing cold water in the place of steam through the heating pipes. The milk, converted into a paste, can then be removed from the pans without adhering to their sides. The milk is thus concentrated to a greatly reduced bulk, which by the samples examined by Dr. Percy would appear to be about $\frac{1}{3}$ the original quantity, the loss being water only. This can afterward be restored, and the milk will then regain its original character. Thus prepared, the paste is in a convenient form for transportation, and is not liable to change so quickly as when in its natural condition. It can be kept in ice for some weeks without undergoing change, and in hermetically sealed cans much longer. Another preparation, known as "solidified milk," is also made for the New York market by a process like one of the French methods above referred to. To 112 lbs. of fresh milk 28 lbs. of sugar are added, together with a teaspoonful of bicarbonate of soda, merely enough to neutralize any slight acidity there might be in the milk. The mixture is then evaporated by the heat of a water bath carefully regulated, and the process is hastened by a current of air made to pass over the surface. An apparatus is kept in operation gently stirring the mixture during the evaporating process, until at last the milk and sugar are reduced to a creamy-looking powder. This when cooled in the air is weighed out into pound parcels, and compressed by machinery into the shape and size of small bricks. These, covered with tin foil, are ready for sale, and are well adapted either for preservation during long voyages or for immediate domestic use.—**MILK, SUGAR OF,** or **LACTINE**, one of the constituents of milk, is prepared in Switzerland as an article of food, and is imported into this country to be used by homœopaths as the vehicle for their medicines, and in other practice as an article of food for infants in teething, being less apt to produce acidity than cane sugar. It is also recommended as a non-nitrogenous article of diet in pulmonary diseases. It is prepared from the whey obtained from milk coagulated with a little dilute sulphuric acid, and left several weeks in a cool place to crystallize. The crystals of sugar of milk are collected and decolorized by animal charcoal and repeated crystallizations. They

consist of $\text{C}_{12}\text{H}_{22}\text{O}_{11} + 5\text{H}_2\text{O}$. They are hard and gritty, rather insoluble in water and alcohol, slightly sweet, and not easily fermentable. When converted into grape sugar by the action of dilute acids, sugar of milk may furnish a spirituous liquor, as noticed in **MILK**. By the homœopaths sugar of milk is regarded as the most inert substance upon the system, and for this reason as well as on account of its great hardness, which causes it to reduce to extreme fineness the substances with which it is ground, they esteem it as the best medium for their medicines, and are by far the largest consumers of it.

MILKY WAY. See **GALAXY**.

MILL. I. JAMES, a British metaphysician and political economist, born at Logie-Pert, near Montrose, Forfarshire, April 6, 1773, died in Kensington, June 23, 1836. Of humble birth, he received his early education at the grammar school of Montrose, whence he was sent by Sir John Stuart to the university of Edinburgh to study for the church. He excelled especially in Greek and metaphysics, listening with deep interest to the lectures of Dugald Stewart, though he afterward departed widely from his system; was for a time private tutor, and was licensed to preach in 1798, but abandoned the profession, and in 1800 removed to London. He became editor of the "Literary Journal," which was soon discontinued, and was afterward an occasional contributor to the principal British reviews. He soon attracted the notice of Jeremy Bentham, was for several years domesticated in his house, and was the chief expositor of his opinions in England. Upon the first establishment of the "Westminster Review" by Bentham, Mr. Mill was the editor and principal contributor. For 10 years much of his time was occupied in writing his "History of British India" (8 vols. 4to., London, 1818; continued to 1835 by Prof. H. Wilson, 9 vols. 8vo., London, 1840-'46), the first complete work, and, as it has been termed, the beginning of sound thinking, on the subject. It was without a rival as a source of information, and the justice of its views appeared in the subsequent measures for the government of that country. Though he had censured the conduct of the East India company, his ability and familiarity with its affairs caused the directors in 1819 to introduce him into their home establishment, where he managed their correspondence with India in the revenue branch of the administration. He subsequently became head of the department of Indian correspondence, one of the most responsible and authoritative positions in the executive service of the company, and lived to see the great principles which he had advocated practically recognized in the government of India. His official duties did not preclude the continuance of his labors as an author, and he became a contributor to the supplement to the earlier editions of the "Encyclopædia Britannica." The articles furnished by him on colonies, education, government, jurisprudence, law of nations, liberty of the press, and prison

discipline were subsequently collected in a volume (London, 1828), and are among his most effective writings. They were reviewed in the 97th number of the "Edinburgh Review" by Macaulay, who, after styling Mill by far the most distinguished of the utilitarian philosophers after Bentham, pronounced him "an Aristotelian of the 15th century, born out of due season. We have here an elaborate treatise on government, from which, but for two or three passing allusions, it would not appear that the author was aware that any governments actually existed among men. Certain propensities of human nature are assumed; and from these premises the whole science of politics is synthetically deduced. We can hardly persuade ourselves that we are not reading a book written before the time of Bacon and Galileo." The work was esteemed by those who accepted its principles as a masterpiece of demonstration. His "Elements of Political Economy" (1821-'2) presented the views of Ricardo in a precise and clear style. His most elaborate work was his "Analysis of the Phenomena of the Human Mind" (1829), an ingenious exposition of the sensational philosophy. The 8 simple elements of consciousness are sensations, ideas, and the train of ideas. By sensation he understands that which exists when the object of sense is present; by ideas, that which exists after the object of sense has ceased to be present; and the train of ideas is only another name for imagination, though he applies the latter term specifically to the train of the poet. From this simple basis he builds up with remarkable subtlety and dexterity a comprehensive system, all the errors or defects of which lie at the very threshold. His conclusions are inevitable if his premises, his representation of the facts of consciousness, be accepted. Sensation, ideation, association, and naming are the elementary processes in his analysis, by which he accounts for all the complex phenomena of the mind, for abstraction, memory, judgment, ratiocination, belief, and the power of motives. By the law of association, which holds a prominent place in the system, he means that ideas recur in the order of the former sensations of which they are the copies. The last publication of Mill was a fragment containing a severe criticism on Sir James Mackintosh's dissertation on the progress of ethical philosophy (1835). He also contributed important articles to the early numbers of the "Westminster Review," on the "Formation of Opinions," the "Ballot," "Aristocracy," and other subjects. II. JOHN STUART, son of the preceding, an English philosopher, born in 1806. He was educated under his father's care, and for many years subjected himself to the severest intellectual training, while pursuing a wide range of studies. His holidays and vacations only diverted without suspending his researches, and his name first occurs in the "British Flora" as an authority for the habitat of flowers. In 1823 he became a clerk in the India house, in which after a se-

ries of promotions he received in 1856 the appointment of examiner of the Indian correspondence, which had been previously held by his father. So thorough was his culture, that the most elaborated mind of our age, as his has been called, seemed almost mature and complete at its first appearance. With reputation for scholarship and ability, he was early regarded by a portion of the disciples of Bentham, prominent among whom was his father, as a writer whose Platonic studies and sympathies were to give a nobler interpretation to the doctrines of the school. He was selected to edit Bentham's "Rationale of Juridical Evidence" (1827), to which he added notes and supplementary chapters. He was a frequent contributor to the journals in favor of advanced liberal views during the agitation of the reform bill. In the "London and Westminster Review," which he conducted from 1835 to 1840, appeared his masterly articles on Bentham and Coleridge, in which his aim was to interpret between their respective admirers, criticizing his own party and reporting truths which it might learn from its opponents. He also wrote for the "Edinburgh Review" and other leading periodicals. He first became widely known by the publication of his "System of Logic, Ratiocination and Inductive" (2 vols., London, 1843), in which the whole character of his philosophy appears. The predominance which he gives to sensation in psychology involves the predominance of induction in logic. He denies the existence of *a priori* truths, affirms that knowledge is limited to phenomena, and ignores causation beyond phenomenal conditions. He conceives of logic only as an organon, method, or body of rules for showing the coexistence and succession of phenomena, and thereby discovering laws; and according to this definition his work is an almost exhaustive manual of procedure in the present state of the science. But it deals only with secondary truths, deems it illegitimate to attempt to pass from the description to the ultimate rationale of our intellectual processes, and regards ethics, politics, and the exact and physical sciences in the same light and by the same method. This fundamental characteristic makes him reduce the inductive method to a strict system, and introduce peculiar views of the grounds of deductive reasoning. His "Essays on some Unsettled Questions of Political Economy" (1844) was preliminary to his second great work, entitled "Principles of Political Economy, with some of their Applications to Social Philosophy" (1848), a subject peculiarly fitted to his adroitness in the treatment of positive problems and palpable interests. He aimed, like Adam Smith, to associate the exposition of general principles with their practical applications, and also to introduce the new ideas, especially respecting currency, foreign trade, and colonization, which had been elicited by discussions subsequent to the publication of the "Wealth of Nations;" to maintain a course of strict scientific reasoning while exhibiting

the economical phenomena of society in their relation to the best social ideas of the present time. His various "Dissertations and Discussions, Political, Philosophical, and Historical," have been collected, chiefly from the "Edinburgh" and "Westminster" reviews (2 vols., London, 1859), and embrace his views on the most important topics. He maintains that scientific certainty is but a relative certainty, and that theology can have no firmer basis than an inference from the analogies of experience; that morality is but a means to an end, that that end is happiness, that approximation to an ideal standard of inward harmony is the method of attaining that end, that the realization of this harmony is not a moral but an æsthetical achievement, and that the utilitarian is entirely different from the selfish view of life; that poetry, music, painting, and sculpture have great social value and educative power; that political questions should be decided by the deliberately formed opinions of a select few, specially educated for the task, whose rectitude of purpose should be secured by rendering them responsible to the many; that the ideal of a rational democracy is not that the people themselves govern, but that they have security for good government; that there is no essential difference between the powers of woman and man, and that she should be his partner in all actual and intellectual enterprises, and in all social and political privileges and responsibilities; and that all history is a progressive chain of causes and effects, the complex facts of each generation being caused by that which preceded it, and moulding that which follows it. He published also in 1859 a work "On Liberty," the object of which is to show that our age manifests an increasing despotism of social and political masses over the moral and intellectual freedom of individuals, that the supremacy of public opinion discourages the strength or intensity of any well marked type of character, that energetic characters on any large scale are becoming merely traditional, and that the only guaranty against the decline of our civilization is to erect by common consent every individual human mind into an impregnable and independent fortress, within which no social authority shall have any jurisdiction. "A state of things, in which a large portion of the active and inquiring intellects find it advisable to keep the genuine principles and grounds of their convictions within their own breasts, and attempt, in what they address to the public, to fit as much as they can of their own conclusions to premises which they have internally renounced, cannot send forth the open, fearless characters, and logical, consistent intellects, who once adorned the thinking world." A Chinese similarity and mediocrity is becoming prevalent, to resist which he maintains that society has no right to intimidate, even by the combined expression of moral opinion, those whose practice evinces a great divergence of moral principle from the ac-

cepted standard, so long as the practice at issue has no bearing on the rights of any other than the offending persons. In his "Thoughts on Parliamentary Reform" (1859) he recommends the extension of the electoral suffrage to all householders without distinction of sex, on condition of proving their ability to read, write, and calculate, and a considerable extension to persons of certain educational qualifications; advocates the permission of 1, 2, or 3 votes to a single elector; and opposes the use of the ballot, on the ground that a universal moral sentiment condemns concealment.

MILL, JOHN, an English biblical scholar, born at Shapp, Westmoreland co., about 1645, died at Oxford, June 23, 1707. He was graduated at Oxford in 1669, where, after receiving various ecclesiastical preferments, he was made in 1685 principal of St. Edmund's hall. His most important work is his edition of the Greek Testament, to the preparation of which he devoted the last 30 years of his life. It was originally undertaken by him at the suggestion and expense of Dr. Fell, bishop of Oxford; but after that dignitary's death, he continued it at his own cost, and paid back to Fell's executors the money advanced by the bishop. Its publication was completed but a short time before his death. This edition, which adopts the received text of Robert Stephens, contains over 30,000 various readings collected from the works of former commentators, the writings of the fathers, and ancient uncollated MSS.

MILLAIS, JOHN EVERETT, an English painter, born in Southampton, June 8, 1829. His taste for art was developed in childhood, and at 9 years of age he gained a medal from the society of arts. About this time, by the advice of Sir Martin Archer Shee, the president of the royal academy, he was placed in Mr. Sass's preparatory school of art in London, whence at the age of 11 he was transferred to the antique school of the royal academy. In 1843 he gained the medal for drawing from the antique. Three years later he exhibited his first picture at the academy, "Pizarro seizing the Inca of Peru," and in the succeeding year obtained the gold medal for the best oil picture, his subject being "The Tribe of Benjamin seizing the Daughters of Shiloh." It was at this period of his life that, partly through the influence of his brother artists, William Holman Hunt and Dante Gabriel Rossetti, partly through his own original views of art, he was induced to reject the academic rules which had been his previous routine, and to adopt the principles of the so called "Pre-Raphaelite school," of which he was one of the original members. The first picture painted by him in the new style was "Isabella," from Keats's poem, exhibited in 1849. In 1850 appeared his "Ferdinand lured by Ariel," and a mystical picture of our Saviour, and in the succeeding year "Mariana in the Moated Grange," the "Return of the Dove to the Ark," and the "Woodman's Daughter." So rigorously did he follow the realistic principles involved in his

new conceptions of art, that the simplicity at which he aimed was decried as an evidence of baldness and poverty, and his pictures were declared to be utterly deficient in the sense of beauty. Their unquestioned power, however, challenged the attention of those who were most hostile to the pre-Raphaelites, and it was conceded that the naturalism which the artist sought to embody in his works was of a higher order than the literal reproduction of nature. His efforts at religious symbolism found few admirers, and were not subsequently repeated. The "Huguenot" and "Ophelia," exhibited in 1852, increased his reputation; and in the succeeding year his "Proscribed Royalist" and "Order of Release," both evincing matured powers of invention and execution, were very generally popular. The latter picture, which tells its own story, is well known through the excellent and widely disseminated engraving by Cousins. In the same year Millais was elected an associate of the royal academy. His remaining works are characteristic though unequal performances, the pre-Raphaelite principle being occasionally somewhat relaxed in the handling and color, as well as in the arrangement of accessories. The principal are the "Rescue," "Autumn Leaves," *L'Enfant du Régiment*, "A Dream of the Past," the "Blind Girl," "The Escape of the Heretic," "Junketing in an Orchard," &c. Some of these works have been severely criticized by Ruskin and others, and by many of his professed admirers the artist is conceived to have reached the limit of his inventive powers. In popular estimation, however, he still stands at the head of his school. He was at one time a contributor to the "Germ," a short-lived periodical, devoted to an exposition of the views of the pre-Raphaelites, and also competed unsuccessfully for the prize offered at the Burns centennial festival for the best verses in honor of the poet. He has sometimes been engaged in the illustration of books and periodicals. Several years ago he was married to the former wife of John Ruskin, who had procured in Scotland a divorce from her husband.

MILLARD, a W. co. of Utah, extending from the Wahsatch mountains westward for about 400 m., with an equal width of about 60 m.; area estimated at 2,400 sq. m.; pop. in 1853, 804. Carson and Walker's lakes are on the W. border, and Sevier river drains the E. portion. Several ranges of mountains traverse the county toward the W. Capital, Fillmore City, which is also the capital of the state.

MILLARD, DAVID, an American clergyman of the Christian denomination, born in Ballston, N. Y., Nov. 24, 1794. His father, Nathaniel Millard, served as a soldier during the latter portion of the revolutionary struggle, after which he became a farmer, and the son was brought up to active labor on a farm. His school opportunities never exceeded 8 months in each year, after he became able to use any kind of farming implement; but when only 17 years of age he was qualified to teach a common

school. In 1815 he entered the work of the ministry, and in 1818 settled as a pastor in West Bloomfield, N. Y., where he resided 14 years. During that time he wrote and published "The True Messiah in Scripture Light." He also edited for several years a monthly magazine called the "Gospel Luminary." In 1837 he accepted a call to Portsmouth, N. H., where he remained 8 years. In 1841, owing to failing health, he visited the Mediterranean and the East, and in 1843 published a volume of his "Travels in Egypt, Arabia Petraea, and the Holy Land." For several years he has been a professor in the Meadville theological school, Penn.

MILLEDGE, JOHN, an American soldier and statesman, born in Savannah, Ga., in 1757, died at the Sandhills, near Augusta, Feb. 9, 1812. At the commencement of the revolution he espoused the cause of the colonies, and was one of the party which, headed by Joseph Habersham, entered the dwelling of Gov. Wright and took him prisoner (June 17, 1775), the first bold revolutionary act performed in Georgia. When Savannah was captured by the British, Mr. Milledge escaped to South Carolina, where he was captured by a party of Americans, and very nearly hanged as a spy. He was present at the unsuccessful siege of Savannah under the com. D'Estaing and Gen. Lincoln, and also at the siege of Augusta; and in South Carolina and Georgia at various places and on various occasions, he did valuable service in the patriot army. In 1780 he was appointed attorney-general, and afterward served frequently in the state legislature. In 1802 he was elected governor of Georgia, and served two terms. He was a representative in Congress from 1792 to 1802, except one term, and U. S. senator from 1806 to 1809. He was the principal founder of the university of Georgia, and purchased and presented the lands on which Athens, the seat of the university, is built. By a special act of the legislature the capital of the state was called Milledgeville in honor of his memory.

MILLEDGEVILLE, the capital of the state of Georgia and of Baldwin co., situated in the midst of a cotton-growing region, on the W. side of the Oconee river, in lat. 33° 4' 10" N. long. 83° 19' 45" W.; pop. about 2,500. The principal public buildings are the state house, a large semi-Gothic structure, the governor's mansion, and Baptist, Episcopal, Methodist, and Presbyterian churches.

MILLENNIUM (Lat. *millē*, 1,000, and *annus*, a year), a period of 1,000 years. In theology this term generally designates the doctrine of a return of Jesus Christ in person before the end of the world, of a first or particular resurrection of the just, who are to reign with Christ on earth, and of the destruction of Antichrist. Those who hold such views are called *millenarians* or *chiliasm* (Gr. *χίλιας*, 1,000). It is admitted on all sides that millenarian views were, if not general, at least very common in the ancient church. The belief was generally founded on Ps. xc. 4, according to which 1,000

years are before the Lord as one day, compared with the account of the creation as given by Moses, the 6 days of creation being taken as designating 6,000 years of toil, and the subsequent sabbath as designating 1,000 years of rest and happiness. Beside these passages, Rev. xx. 1-6 is especially quoted by millenarians in support of their views. Millenarianism prevailed chiefly among the Jewish Christians, who retained after their conversion the hope of the Jewish nation, that they would rule over all other nations under a royal Messiah. The Ebionites, the Nazareans, and Cerinthians all strongly advocated it; and Montanus, and the sect which was called after him, regarded it as a fundamental doctrine of the Christian religion. The early fathers of the church also declared themselves generally in favor of the doctrine; Papias, Justin, Irenæus, and Tertullian all clearly teach it; and Papias appealed in support of his view to apostolic traditions. On the other hand, however, the Epistles of Clement of Rome and Ignatius of Antioch, and the Epistle to Diognetus, are silent about it. Justin, though himself a believer in the millennium, knew many orthodox Christians who were not; yet none of the apostolic fathers openly opposed it. The first opponent of whom we know was the Roman presbyter Caius, who designated the doctrine as an invention of the arch-heretic Cerinthus. He was soon followed in his opposition by the whole Alexandrian school, especially by Origen; and it is regarded as certain, that at this time the churches of Rome and Alexandria rejected the doctrine. Still it continued to find advocates during the 3d century, among whom Tertullian, Nepos, bishop of Arsinoë, and Methodius, bishop of Tyre, were prominent. In the 4th century, though it had still many adherents among the people, it found no longer any advocate of note among the Christian writers; yet Jerome, who did not believe in it himself, did not dare to condemn it, in consideration of the many pious and learned advocates it had found in former centuries. From the 5th century, millenarianism began to die out; it was temporarily revived, toward the close of the 10th century, by the popular belief in the approaching end of the world, and a little later by the abbot Joachim de Floris, the Spirituals, the Apostolic Order, Peter de Oliver, and other heretics of the middle ages; but it never regained great strength.—The reformation of the 16th century gave a new impulse to the millenarian views. Common opinion identified the pope with Antichrist, and regarded the expected downfall of the church of Rome as foreshadowing the approach of the millennium. But when the Anabaptists assumed in 1584 to erect the new Zion, both the Lutheran and Reformed churches declared themselves against this caricature of the old Christian doctrine. Yet, although little favored within the state churches, it was preached with enthusiasm by many sects and theologians of the 16th and 17th centuries, among

whom were Weigel and the Moravian bishop Comenius in Germany, Jurieu in France, the Labadists in the Netherlands, and Joseph Mede and Jane Lead (died 1704) in England.—A third period in the history of millenarianism may be commenced with the writings of the esteemed theologian Johann Albrecht Bengel. He reintroduced it into Protestant theology, where it has ever since been advocated by a number of prominent theologians. The ingenious prelate Oetinger (died 1782) brought it into connection with his favorite theosophic views. Hahn (the founder of a pietistic sect in Würtemberg), Stilling, Lavater, and Hass gave it a wide circulation among the lower classes of the people in Germany and Switzerland. With Rothe (*Theologische Ethik*, vol. ii.) millenarianism forms an organic link in his theosophic system. In opposition to the "spiritualism" of modern exegesis, it was advocated, with exegetical arguments, by Hoffmann, Delitzsch, Kurtz, Hebart, and others; while Thiersch, Nitzsch, P. Lange, and Ebrard supported it from a dogmatical as well as an exegetical standpoint. Swedenborg taught that the last judgment took place in 1757, and that the New church or church of the New Jerusalem had actually been formed both in heaven and on earth. After Germany, England and America have been the chief fields of modern chiliasm. The "Catholic Apostolic Church," organized by Edward Irving, laid great stress on the belief that the kingdom of glory was very near. Millenarian views lie also at the foundation of Mormonism, the people who hold that belief calling themselves "Latter Day Saints" in reference to the near approach of the last day. In the United States a great agitation was called forth by the preaching of William Miller, who sought to prove from the Scriptures that the second advent of Christ would occur about 1843. He not only found numerous believers in most denominations, but also occasioned the organization of a new denomination of Adventists.—Numerous as the millenarians have been in various periods of the Christian church, their views widely differ respecting most points, except the duration of the millennium, which nearly all of them fix at 1,000 years. The beginning of the millennium was fixed by Hippolytus at the year 500, by Jurieu at 1785, by Bengel at 1836, and by others at other dates. Many agree in expecting it between 1879 and 1887. Commonly the earth is believed to be the only place of the millennium, and Jerusalem its central point of union.—A good history of millenarianism in the Christian church is still a desideratum, as the works published do not exhaust the subject. See Corrodi, *Kritische Geschichte des Chiliasmus* (Frankfort, 1781); D. T. Taylor, "The Voice of the Church on the Coming and Kingdom of the Redeemer; a History of the Doctrine of the Reign of Christ upon Earth," revised by Hastings (2d ed., Peacedale, R. I., 1855).

MILLEPORE (*millepora*, Linn.), a genus of hydroid medusæ. The animals live in communities, which take on various arborescent

and incrusting shapes; they deposit much carbonate of lime in their tissues, so that the medusa stock is in outward appearance almost solid, with minute pores on the surface which contain the animals. A cross section of this stony skeleton shows that the minute individuals of the community constantly grow outward in the direction of their longitudinal axis, forming as they proceed long calcareous tubes, which are so intimately cemented together as to make a compact mass. Across these tubes, at short intervals, there are formed little transverse platforms, which divide the tubes into joints or cells. These platforms are deposited by the base of the animal, and are of high importance in classification; by them is characterized Milne-Edwards's division of the *tabulata*, which includes *millepora*. Till within a short time all zoologists have placed the millepores among polyps; Prof. Dana, for instance, ranks them in the family of *favositidae* in the tribe *madreporacea*, in his "Synopsis of the Report on the Zoophytes of the U. S. Exploring Expedition" (1859). In the winter of 1857-'8 Prof. Agassiz succeeded, for the first time, in observing the animals of *millepora alcicornis* in Florida, and was surprised to find them not polyps, but true hydroid medusæ, resembling *hydractinia*. This observation gives great importance to the medusæ, as represented among the fossils, for the *tabulata* are found abundantly as low as the silurian formations.—See the "British Fossil Corals," by Milne-Edwards, in the "Transactions of the Paleontographical Society;" Dana's "Zoophytes;" the "American Journal of Science," vol. xxvi. p. 140 (1858); and Agassiz's "Contributions to the Natural History of the United States," vol. iii.

MILLER, a central co. of Mo., traversed by Osage river, here navigable during 8 or 4 months of the year; area, 570 sq. m.; pop. in 1856, 4,024, of whom 165 were slaves. The surface is diversified and well timbered with walnut, sugar maple, and other valuable woods. The soil of the river bottoms is fertile. The productions in 1850 were 144,994 bushels of Indian corn, 14,724 of wheat, 34,608 of oats, and 182 tons of hay. Capital, Tuscumbia.

MILLER, EDWARD, an American physician and author, born at Dover, Del., May 9, 1760, died in New York, March 17, 1812. He received his early education at home, and at the age of 14 was sent to the Newark academy in Delaware. After leaving the academy he commenced the study of medicine under the direction of Dr. Charles Ridley, an eminent physician of Dover, and attended two courses of medical lectures in the university of Pennsylvania, after which he spent about a year in the military hospital at Baskingridge, N. J., in the capacity of a surgeon's mate. In 1782 he went to France as the surgeon of an armed ship. On his return in 1783 he entered on the practice of medicine, first in Somerset co., Md., and afterward in his native town. In 1785 he received the degree of M.B., and in 1788 was graduated as M.D. in the university

of Pennsylvania. In Dover he continued 16 years in an extensive practice, and in 1796 he removed to the city of New York. Within a few months after, with Dr. Mitchill and Dr. Smith, he commenced the publication of the "Medical Repository," the first American medical journal. He early lost by death the co-operation of Smith, but continued with his colleague Mitchill the regular issue of the work to the completion of the 14th annual volume. In 1803 he was appointed resident physician for the city of New York, which office he held, with the intermission of one year, to the close of his life. In 1805 he was elected a member of the American philosophical society, and upon the organization of the college of physicians and surgeons of New York was appointed by the regents of the university professor of the theory and practice of physic in that institution. In 1809 he was chosen one of the physicians of the New York hospital. His chief publications beside his inaugural dissertation, were his medical papers in the "Repository," and his "Report on the Yellow Fever of New York in 1805," in a letter to Gov. Lewis. This last document secured him a wide renown, and is the source from which most authors of a more modern date have drawn their arguments in behalf of the doctrine of the domestic origin and non-contagious nature of yellow fever. His medical writings, with a biographical sketch, were published by his brother, the Rev. Samuel Miller, D.D. (8vo., 1814).

MILLER, ÉMANUEL, a French philologist, born in Paris in 1809. In 1834 he received an appointment in the manuscript department of the royal library, and in that capacity made visits to some of the principal libraries of Spain and Italy, whence he procured copies of valuable original manuscripts. Among the results of his explorations were a *Supplément aux dernières éditions des petits géographes Grecs* (Paris, 1839); *Catalogue des manuscrits Grecs de la bibliothèque de l'Escurial* (4to., 1848); and *Poésies Grecques inédites de Manuel Phil.* In 1851 he published at Oxford, under the title of "Refutation of Heresies," the text of a manuscript procured from Mt. Athos by M. Minoret Mynas, and which he believed to be an original treatise of Origen. Of this work, since generally attributed to Hippolytus, he has announced a translation. In 1840-'46 he published 6 volumes of a *Revue de bibliographie analytique*, which met with but moderate success; and he has edited a number of minor Greek authors, beside contributing largely to the *Journal des savants*. He was also one of the principal editors of the *Recueil d'itinéraires anciens* (4to., 1844).

MILLER, HUGH, a British geologist, born in Cromarty, on the E. coast of Scotland, Oct. 17, 1802, died at Portobello, near Edinburgh, Dec. 26, 1856. He belonged to that half Scandinavian population inhabiting the shores of the German ocean from Fife to Caithness. On his father's side he was 4th in descent in a line

of sailors from John Feddes, one of the last of the buccaneers on the Spanish main, who returned to Cromarty to enjoy his money, and built "the long, low house" in which his distinguished great-grandson passed his youth. On his mother's side he was of highland blood, and 5th in descent from Donald Roy of Ross-shire, famed for his piety and his second sight. His father was drowned in a tempest, a fate which had befallen several of his ancestors, in 1807; and from that time, though still living with his mother, he was chiefly under the care of two maternal uncles, who had greater influence and authority over him until the age of manhood than any other persons. One was a harness maker and the other a cartwright, and he accounts them the most important of his schoolmasters. Uncle Sandy (Alexander) encouraged his early bent toward natural history, and taught him much about rocks, clouds, rains, tides, trees, ferns, shell fish, sea fowl, and insects. Uncle James interested him in human history, and gave him his liking for traditional lore, Scottish antiquities, social habits, and individual eccentricities. The tastes and predilections of both uncles were deeply impressed on him, and wherever he went in later life the geology and humanity of the district seemed equally to attract him. In his 5th year he was sent to a dame's school, where he learned to read—"that grand acquirement of my life." He was thence transferred to the grammar school of Cromarty, where he went through the ordinary course of rudimentary studies. He even began Latin with a view to college, but from distaste failed in it completely, being usually at the nether end of a very poor class, which position even he maintained only by displaying an unaccountable facility in translation. The master read aloud every morning in English the task assigned for the day, and Hugh was able to remember the whole rendering in its order, and to give it back in the evening word for word. Much of the leisure secured in this way was employed in reading translations from the classics by stealth. About his 15th year he attended for some time a subscription school set up as a rival to the grammar school. But from this whole amount of pedagogy he derived, according to his own estimate, only one advantage, namely, the faculty of reading books, with the correlative accomplishment of writing. From the time when he groped his way through the shorter catechism and the Proverbs into the Bible class at the dame's school, he had been an omnivorous reader. First came a course in the classical romances of childhood, "Jack the Giant Killer," "Jack and the Bean Stalk," the "Yellow Dwarf," "Blue Beard," "Sindbad the Sailor," "Aladdin and the Wonderful Lamp," and other similar works. Pope's translation of Homer, the "Pilgrim's Progress," "Robinson Crusoe," "Gulliver's Travels," the "Miracles of Nature and Art," the "Adventures of Philip Quarll," the voyages of Byron, Anson, Drake, Dampier, and Raleigh,

and several works on Scottish martyrology, had all been perused with avidity before his 11th year. At that age his uncle James placed in his hands a copy of Blind Harry's "Wallace," as modernized by Hamilton, which was followed by Barbour's "Bruce," and occasioned a fit of enthusiastic Scotticism. He had already acquired a reputation among his class fellows as a narrator of stories; and having exhausted the subjects of his reading and the various adventures that he had himself heard told, he was accustomed to extemporize with great success the wildest biographies. The British essayists, Pope, a collection of minor poems, &c., of the wits of Queen Anne, Goldsmith, Shakespeare, and divers translations from Latin, French, and German, had been added to his miscellaneous intellectual stock before his 17th year. Moreover, he had begun to write verses; and his last exploit as a school boy was to engage in a fight with his master on the school floor, and, in revenge for having been thrown, to write a poetical satire upon him. Meantime, other branches of his education had been going on outside of the school. He was the leader in excursions along the precipices and into the caves on the coast. He had learned to collect on the beach and to distinguish from each other the various rocks of the locality, as porphyries, granites, gneisses, quartz, and mica schists, and had discovered for himself that Cromarty possessed among its minerals one precious stone, the garnet; and his observations in other departments had been encouraged and corrected by his uncle Sandy, who, as he always claimed, knew more of living nature than many professors of natural history. He had studied scenery, customs, and physiognomies in the highlands of Sutherlandshire, among his Gaelic cousins; had heard the story of Culloden from men who fought in the battle; had conversed with an old lady who witnessed the last witch-burning in the north of Scotland; and had acquired a habit, which marks his life and his writings, of studying historical monuments as well as geological formations, collecting local legends as well as fossils, delighting as much to discover a kelpie as a pterodactyl, and regarding types of character and phases of society in connection with the facts of science. The foremost youth in the district, his uncles wished him to prepare for Aberdeen college, and there to study for the church; but he demurred, declaring that he had no call to the sacred office, and they admitted that he had better be any thing than an uncalled minister. A trade was therefore resolved upon, and he was apprenticed for 3 years to one of his relatives, who was a stone mason. From his 17th till his 34th year he led the life of an operative mason, journeying in summer to pursue his labors in different parts of Scotland, devoting all his leisure to earnest intellectual cultivation, reading all kinds of books on summer evenings and at home during the winter, and cherishing a belief from the beginning that literature and perhaps nat-

ural science would after all prove his proper vocation. During the first part of this period (1818-'25), as an apprentice and journeyman, he was subjected to all the coarse and rough experiences of his trade, working as one of a gang in quarries or in sheds, and passing his evenings in wretched highland bothies or in hovels in lowland villages. He afterward exchanged the life of a journeyman, working season after season for different masters, for that of a jobbing mason, undertaking private commissions in the way of his trade, such as the sculpturing and lettering of tombstones, stone dials, and the like; yet his habits of work continued in all respects to be those of a common mason, and his domestic accommodations those of any frugal Scotch mechanic. During this most laborious period of his life he formed an intimate and extensive acquaintance with the best English and Scotch literature, embracing not only the departments of fiction, history, and poetry, but the philosophical works of Locke, Kames, Hume, Reid, Adam Smith, and Dugald Stewart. The latter he seems to have grappled with rather as a matter of conscience than of real liking. He seized upon every work of natural science that fell in his way, and moreover wrote a great variety of verses, rhapsodies, and reflections. His various scenes of labor made him familiar with the scenery, antiquities, and social peculiarities of different parts of Scotland. But his greatest progress was in geology. Starting with hardly more than an empirical knowledge of the mineral characters of rocks, he soon detected the wonders of the fossil world in quarries remarkably rich in organisms. Wherever he went, from the shores of the Moray frith to those of the frith of Forth, the hammer was in his pocket, and his eye was searching for fossil specimens. Combining what he saw with what he read, he became, while yet hardly aware of it, not only a self-taught geologist, but a geologist capable of teaching others. To this period belong his discoveries in the old red sandstone, which only required to be known to insure him distinction in the scientific world. He had many friends, whom he has strikingly characterized in his work entitled "My Schools and Schoolmasters," with whom he came into more or less frequent contact, and who exercised an educating power upon him. There were John Fraser, the prince of north country masons, who could do with ease 8 times as much work as any other man; Dr. McCrie, the biographer of John Knox; "Charles," the black-guard hero of the south country squad; and above all others William Ross, the house painter, weak-bodied and diffident, but with the genius of a poet and artist, who seems to have been *par excellence* the friend of his life. In 1825, work failing in the north, he sailed for the south of Scotland, and went from Leith to the capital. There he was occupied for two years, till his health began to fail, and he learned that few Edinburgh stonecutters pass their 40th year, and not one in 50 reaches his 45th. He

therefore returned to Cromarty, accustomed to contemplate with rather pensive than sad feelings an early death, and soon after became seriously interested in the personal bearing of religious concerns. Until this time he describes himself as wavering between two extremes, now a believer and anon a sceptic, the belief being instinctive, the scepticism the result of some intellectual process. The result of his thoughts and conversations was that he found rest in the fundamental principles of Scotch evangelicism. His attainments soon made him a local celebrity; geologists in other towns corresponded with him; Cromarty ladies began to walk up to where he was at work to have the pleasure of conversing with him; and he was honored by an election to the office of town councillor. He published a volume of "Poems written in the Leisure Hours of a Journeyman Mason" (1829); contributed a series of letters to the "Inverness Courier" on the herring fishery, which were collected in a volume; discovered deposits of ichthyic remains belonging to the second age of vertebrate existence, sufficient to prove not only the existence but the structure and varieties of fishes at that early period; and at length exchanged manual labor for the office of accountant in a bank opened at Cromarty. During the first two years of his accountantship his marriage took place, his "Scenes and Legends of the North of Scotland" was published, and he became a frequent contributor to periodicals. The non-intrusion controversy was then at its height in the Scottish church, and immediately after the adverse decision of the house of lords in the Auchterarder case he published his celebrated "Letter to Lord Brougham," which, as Mr. Gladstone affirmed, showed a mastery of pure, elegant, and masculine English that even an Oxford scholar might have envied. The leaders of the Free church were then looking for a man to edit their contemplated organ, and at once selected Mr. Miller, who in 1840 removed to Edinburgh as editor of the "Witness." As a Scottish journalist he held a high and almost unique place. His leading articles were remarkable for their deliberate thought, elevated moral tone, strong Presbyterian feeling, and fine literary finish, and exerted a powerful influence on the formation of public opinion. His genius for description, literary culture, and relish for peculiar social characteristics appear also in his account of a vacation tour, entitled "First Impressions of England and its People." But his greatest eminence was achieved in the department of practical and speculative geology. He went to Edinburgh with the results of many years of scientific observation and reflection, with a collection of belemnites, fossil fishes, and other objects of natural history, and with a collection of thoughts and speculations about them, which in his own judgment formed his most valuable capital. During the first year of his editorship he published a series of papers, afterward known as

ectively under the title of "The Old Red Sandstone, or New Walks in an Old Field," in which he detailed the story of his researches and revealed his discoveries of fossils in a formation which had till that time been deemed almost destitute of them. These were immediately recognized by savants as important additions to geological science. At the meeting of the British association in 1840 his labors were the principal theme; the fossils which he had picked up in boyhood in his native district were promoted to their due rank as *pterichthys Milleri*; and Murchison and Buckland spoke of his descriptive talent as casting plain geologists like themselves into the shade, and making them ashamed of their meagre style. His severe tasks endangered his health and compelled him to forego all literary labor during the greater part of 1845 and 1846; but he returned from his seclusion only to be more intimately associated with Dr. Chalmers in the counsels of the Free church. The appearance and popularity of the "Vestiges of the Natural History of Creation," embodying the development theory, and aiming to transfer the work of creation from the realm of miracle to that of natural law, caused him to prepare a reply, entitled the "Footprints of the Creator, or the Asteropis of Stromness," an able and strongly fortified exposition of the opposite view, which had a very wide circulation in England and America. One of his most interesting works is "My Schools and Schoolmasters, or the Story of my Education," a full review of his life until the time of his settlement in Edinburgh. He published in 1848 the "Geology of the Bass Rock," lectured on geological subjects in Edinburgh and London, read papers before the British association, and had just completed at the time of his death his "Testimony of the Rocks," in which he discusses the biblical bearings of geology. He toiled upon this task night and day, with little sleep or exercise, until, after a week or two of cerebral disorder, he himself became conscious that his mind was on the verge of ruin. He felt occasionally as if a very fine poignard had been suddenly passed through and through his brain, and in some of his paroxysms his face was a picture of horror before which even his wife shrank in dismay. He was found lifeless in his study, his chest pierced with the ball of a revolver pistol, which was found lying close by. It appeared that a trance more narrowing than ever befell him, and on waking he must have meditated self-destruction. In a pathetic note left for his wife, he wrote: "A fearful dream rises upon me. I cannot bear the horrible thought." His principal works have been republished in America.—See the "Life and Times of Hugh Miller," by Thomas N. Brown (republished, New York, 1860).

MILLER, JAMES, an American general, born at Peterborough, N. H., April 25, 1776, died in Temple, N. H., July 7, 1851. He was educated at the bar, but in 1808 entered the army as major in the 4th infantry. In Aug. 1812, he

was brevetted as colonel for distinguished services, and in the succeeding May participated with credit in the capture of Fort George. In March, 1814, he was appointed colonel of the 21st infantry, in which capacity he accompanied the invading army of Brown into Canada, and fought with gallantry at the battles of Chippewa and Lundy's Lane. The success of the Americans in the latter conflict was mainly due to the capture of a British battery by his command, and his name was long celebrated in connection with his reply to Gen. Scott's inquiry if he could take the battery: "I'll try, sir." For these services he was brevetted as brigadier-general, and received from congress a gold medal. He resigned his commission in the army in 1819, upon being appointed governor of Arkansas territory, which office he held until March, 1825. In the latter year he was made collector of customs in Salem, Mass., where he remained until 1849, when he retired into private life.

MILLER, JOSEPH, an English comic actor, whose name has long been associated with the literature of facetiae, born probably in London in 1684, died there in 1738. He was a popular actor on the English stage in the early part of the last century, and performed with repute in several of Congreve's best comedies, particularly in "Love for Love" and the "Old Bachelor," to the success of which he is said to have materially contributed. In 1739 a book of jests passing under his name, and supposed to be the compilation of John Mottley, author of a life of Peter the Great, was published in London, and has since gone through numerous editions. As one of the chief repositories of English humor of the broader kind, it has gained a celebrity which preserves the name of its assumed author.

MILLER, SAMUEL, an American divine, born near Dover, Del., Oct. 31, 1769, died in Princeton, N. J., Jan. 7, 1850. He was the son of the Rev. John Miller, a native of Boston, who early settled as a Presbyterian clergyman in Delaware, and brother of Edward Miller, M.D. He was graduated at the university of Pennsylvania in 1789, studied theology, partly under his father and partly under Dr. Nisbet, president of Dickinson college, was licensed to preach by the presbytery of Lewes in 1791, and in June, 1798, was installed as colleague pastor with Drs. Rodgers and McKnight of the first Presbyterian church in the city of New York. In 1804 the degree of D.D. was conferred upon him by his *alma mater*; and in 1806 he was moderator of the general assembly of the Presbyterian church. In 1818 he accepted the professorship of ecclesiastical history and church government in the theological seminary at Princeton, and continued to discharge the duties of this office with great fidelity and ability till near the close of his life. He tendered his resignation to the general assembly in May, 1849, and in accepting it they testified in the strongest manner their high appreciation of his character and services. Dr. Miller was a devoted friend of the Presbyterian church, and enlisted vigorously in the

controversy which resulted in its division, though he was always a model of controversial dignity and decorum. He was the author of "A Brief Retrospect of the Eighteenth Century" (2 vols. 8vo., New York, 1808; 3 vols. 8vo., London, 1805); "Letters on the Constitution and Order of the Christian Ministry" (12mo., 1807), with a "Continuation" (1809); "Memoirs of the Rev. John Rodgers, D.D." (8vo., 1818); "Letters on Unitarianism" (8vo., Trenton, 1821); "Letters on Clerical Manners and Habits" (12mo., Philadelphia, 1827); "An Essay on the Office of Ruling Elder" (12mo., New York, 1831); "Letters to Presbyterians" (1838); "Discourses on Infant Baptism" (1834); "Presbyterianism the truly Primitive and Apostolical Constitution of the Church of Christ" (Philadelphia, 1835); "The Primitive and Apostolic Order of Christ vindicated" (1840); "Letters from a Father to his Sons in College" (1843); "A Sermon on the Ruling Eldership, with an Appendix" (1843); "Thoughts on Public Prayer" (1849). He also wrote the "Life of Jonathan Edwards" in Sparks's "American Biography," and published upward of 40 occasional discourses, addresses, and lectures, in pamphlet form, with several biographical sketches, introductory essays to the works of others, &c.

MILLER, STEPHEN FRANKS, an American lawyer and author, born in North Carolina. In early youth he removed to Georgia, where he was admitted to the bar in his 22d year, soon after which the legislature elected him solicitor-general of the southern circuit. When his term of office expired he became a citizen of Alabama, where he continued the practice of his profession until a severe bronchial affection compelled him to engage in other pursuits; and from 1840 to 1847 he edited "The Monitor," a whig journal published at Tuscaloosa. In 1848 and 1849 he resided in New Orleans, where he was associated in the editorial management of "De Bow's Review" and the "Daily Commercial Times." His health failing, he removed to Oglethorpe, Ga. He is the author of the "Bench and Bar of Georgia" (2 vols., 8vo., Philadelphia, 1858); "Wilkins's Wylder, or the Successful Man" (1860); and of a memoir of the late Gen. David Blackshear.

MILLER, THOMAS, an English author, born in Gainsborough, Lincolnshire, Aug. 31, 1809. His parents, being in humble circumstances, could give him no better education than mere reading and writing, and he became a farmer's boy. He devoted his leisure hours to study, and while following the trade of a basket maker began to attract attention by his poetical effusions and by occasional pieces in prose, chiefly describing rural life and scenery. Coming under the notice of Moore, Campbell, and Rogers, the last named enabled him to establish himself as a bookseller, and thenceforth he became an industrious writer. Among his numerous prose works are "Royston Gower," "Fair Rosamond," "Lady Jane Grey," "Godfrey Malvern," and other novels; a "History of the Anglo-Saxons;"

lives of Turner, Beattie, Collins, &c.; and particularly his country books, including "A Day in the Woods," "Beauties of the Country," "Rural Sketches," "Pictures of Country Life," "Country Scenes," &c. In 1842 appeared his first volume of poems, a collection of pieces contributed to various periodicals. He subsequently published the "Language of Flowers" and other pieces in verse.

MILLER, WILLIAM, the founder of the sect of Millerites or Second Adventists, born in Pittsfield, Mass., in 1781, died in Low Hampton, Washington co., N. Y., Dec. 20, 1849. In the war of 1812 he commanded a company organized to protect the northern frontier, and held the commission of captain. His early facilities for education were slight, and he seems never to have been master of what are usually deemed the requisite resources for biblical criticism; but in 1838 he began to lecture on the speedy second coming of Christ, announcing, in accordance with his interpretation of the prophecies, that the earth was to be destroyed in 1841. Even the day was specified, if not by himself by some of his principal followers. His earnest and confident manner attracted attention, his scriptural and historical arguments seemed to many erudite and cogent, and after a few years of constant travel and preaching his disciples were reckoned at from 80,000 to 50,000. They belonged not only to the United States, but to British America and Great Britain, and had a weekly organ, the "Advent Herald," edited and published in Boston, and still continued by the Rev. J. V. Himes. After the failure of their prediction in 1843, the interpretations of the leaders of the sect varied somewhat, but several different years and days were successively designated for the termination of all things; and in some localities the Millerites more than once attired themselves in white and stationed themselves in graveyards and on the roofs of houses, waiting for the appearance of the Lord. The sect still exists, but with greatly diminished numbers, and holds that the second advent of Christ is very near, without claiming to be certain of the precise date.

MILLER, WILLIAM ALLEN, an English chemist, born in Ipswich, Suffolk, Dec. 17, 1817. He was educated at the merchant tailors' school and at the school of the society of Friends at Ackworth, Yorkshire, and at 15 years of age was apprenticed to his uncle, who was surgeon to the general hospital in Birmingham. At the expiration of 5 years he entered the medical department of King's college, London, where he pursued the study of chemistry under Dr. Daniell, whom he occasionally assisted in his laboratory. In 1840 he passed some time in the laboratory of Liebig in Giessen, and in the same year took his degree of M.D. and became demonstrator of chemistry in King's college. In 1845 he succeeded Prof. Daniell in the chair of chemistry, a position which he still holds. He has contributed numerous papers to the scientific periodicals, and is the author of an important

reatise entitled "Elements of Chemistry, Theoretical and Practical." He is president of the chemical society, assayer to the mint and to the bank of England, and was until recently vice-president of the royal society.

MILLER, WILLIAM HALLOWA, an English physicist, born about the beginning of the present century. He was graduated at St. John's college, Cambridge, in 1826, subsequently became a fellow and tutor of the same college, and in 1832 succeeded Prof. Whewell in the chair of mineralogy, which he still occupies. He is the author of several papers on crystallography, published in the "Transactions" of the Cambridge philosophical society, and was one of the first to introduce into England the method of representing crystalline forms by their spheres of projection, and to employ Dr. Wollaston's goniometer in the measurement of the angles of crystals. A more important production than any of these was his edition of Phillips's "Elementary Introduction to Mineralogy" (8vo., 1852), prepared in conjunction with Henry J. Brooke, but of which the greater part was done by himself, the original treatise being reconstructed and enlarged. In 1838-'40 he afforded the parliamentary commission appointed to investigate the subject many valuable suggestions with reference to the new standard of weight intended to replace that lost at the destruction of the houses of parliament in 1834; and in 1843 he became a member of a second commission for superintending the construction of new parliamentary standards of length and weight, the report of which in 1854 ascribes the chief credit for the successful termination of its labors to his exertions. On this subject he read before the royal society a paper "On the Construction of the Imperial Standard Pound and its Copies of Platinum, &c." Among his other published works are "Elements of Hydrostatics," "Treatise on Crystallography," and "Treatise on the Differential Calculus."

MILLET (Lat. *milium*), a name applied to several distinct plants of the natural order *graminacea*, remarkable for their fertility in seed-bearing. The millet cultivated for centuries in Europe and Asia seems to be designated by Linnaeus as the *panicum miliaceum*, an annual grass, native of India and known as *warree*. Its early cultivation in the East seems determined by being mentioned in Sanscrit writings, and it is averred that two sorts were introduced into China in 2822 B. C. The Hungarian millet (*panicum Germanicum*) has been cultivated in Massachusetts to some extent from seeds received from the patent office at Washington. It is an annual forage plant introduced in 1815 into France, where its cultivation has become considerably extended; it is thought to contain a large percentage of nutriment. This species is probably identical with the Italian *setaria*, or Bengal grass (*setaria Italica*, Beauvais; var. *Germanica*, Kunth), having an annual root; stem 4 or 5 feet high; leaves 12 to 18 inches long, rather broad, flat, serrulate on the margins;

sheaths striate, pubescent on the margin; ligules beard-like. Its mode of inflorescence is in a sort of contracted panicle resembling a spike, which is 3 to 6 inches long and of a sub-cylindrical shape. Some years ago the culture of this plant was introduced into Pennsylvania, and excited considerable interest for some time among the farmers, as affording valuable fodder when the usual hay crop was deficient. It was soon found, however, not to be as valuable as the usual fallow crops of oats and barley, of which it occupied the place, and was moreover remarkably liable to damage from rain; and the cultivation was soon abandoned. The seeds of millet are sometimes used for human food, but they are chiefly employed in feeding fowls and domestic animals. A bushel of seeds has been produced on 6 square rods of land. There are several species of *setaria* which appear in waste places and are regarded as weeds, but having the same characteristics in respect to producing abundance of seeds. Among these are *S. viridis*, or green bottle grass, with a cylindrical, green, bristly, compound spike; *S. verticillata*, with the spike made up of interrupted verticils of spikelets, and the bristly involucre of the florets retrose, scabrous; also the glaucous-leaved bottle grass (*S. glauca*), with broad leaves, and long, dense, cylindrical spikes, which turn to a tawny yellow color as they ripen their seeds, regarded as pests in gardens, and appearing after the usual weeding is over. These, though vulgar weeds and very ordinary grasses, are yet in natural affinity related to the millet.—In the colder woods of the northern United States is a plant designated as millet grass (*milium effusum*, Linn.), with a smooth stem 3 to 6 feet high; broad, flat, and thin leaves; a spreading panicle 6 to 9 inches long. This plant is of no known value, but is a representative of the genus *milium*, which, according to Persoon, embraces 15 species growing in widely separate regions of the globe. The Indian millet, or the *durra*, is however a species of *sorghum* (*S. vulgare*, Pers.), as also the drooping millet or Guinea corn (*S. cornutum*, Willd.), both natives of India. This genus is represented in our cultivation by the broom corn (*S. saccharatum*); and the Chinese sugar cane, *imphoe*, or *sorgho sucre*, is well known. Mr. Charles J. Sprague, in the "Proceedings of the Boston Society of Natural History" for April, 1858, arrives at the conclusion, after careful examination of 81 specimens of what were sent to him for 4 distinct species, that the *sorghum vulgare* or Indian millet is the parent and type of this group; a plant which has been cultivated for untold centuries as forage and as food for man and animals. The sorghums, according to Dr. Charles Pickering, are all tropical and oriental plants, he never having found any species on the islands of the Pacific. Some species of *holcus* (Linn.), which formerly included many forms now known as *andropogon* and *sorghum*, are mentioned as among the most important kinds

of millet. Of these, one of the largest is the black millet (*H. niger*) of Arduino, who wrote on the genus *holcus* or *sorghum* in 1786. At the Cape of Good Hope is a species known as the Caffre millet (*H. Cafer*) of the same author; and in Persia is a species called the two-colored millet (*H. bicolor*, Linn.).

MILLIN, AUBIN LOUIS, a French archæologist, born in Paris, July 9, 1759, died Aug. 14, 1818. He was keeper of the museum of antiquities in the national library. His principal works are: *Peintures des vases antiques*; *Monuments antiques inédits*; *Galérie mythologique*; *Voyage dans les départements du midi de la France*, and *Histoire métallique de la révolution Française*. His "Medallie History of Napoleon," left incomplete, was published in English by J. Millingen (London, 1819). He was the founder of the *Magasin encyclopédique* and *Annales encyclopédiques*.

MILLOT, CLAUDE FRANÇOIS XAVIER, a French ecclesiastic and historian, born at Ornans, Franche Comté, in 1726, died in Paris, March 21, 1785. He entered the order of Jesuits, and became professor of rhetoric at their college in Lyons; but his relation with them was brought to a close by their objections against his eulogy of Montesquieu. He now devoted himself to the preparation of historical works suited for schools, which obtained for him in 1768 the chair of history at the college of nobles in Parma founded by the marquis of Felino. In 1777 he became a member of the French academy, and in 1778 preceptor of the duke d'Enghien; and he afterward received a pension of 4,000 francs. His works on French, English, and general history were united under the title of *Œuvres de l'abbé Millot* (15 vols., 1800).

MILLS, a S. W. co. of Iowa, bordering on Nebraska, from which it is separated by the Missouri river, and drained by the Nishnabotona river and branches; area, about 400 sq. m.; pop. in 1859, 4,881. The productions in 1859 were 326,218 bushels of Indian corn, 10,420 of wheat, 26,907 of potatoes, 8,878 of oats, 80,987 lbs. of butter, and 8,540 of wool. Capital, Greenwood.

MILLS, CHARLES, an English historian, born at Greenwich in 1788, died in London in 1825. He studied law, but abandoned it for literary pursuits. His principal works are: "History of Mohammedanism" (8vo., London, 1817); "History of the Crusades" (2 vols. 8vo., 1819); and "History of Chivalry" (2 vols. 8vo., 1825).

MILLS, CLARK, an American sculptor, born in Onondaga co., N. Y., in 1815. He lost his parents in his childhood. He commenced learning the trade of a millwright, but soon abandoned it for that of a plasterer. In 1835 he went south, and after a brief residence in New Orleans settled in Charleston, S. C., where he worked at his trade for 9 years. From the time he was 23 years of age he manifested a taste for sculpture, and devoted all his leisure to its study, and to experiments in forming plaster busts. He at length began to attract atten-

tion, and undertook a marble bust of John C. Calhoun; and although his first effort was much ridiculed, he persevered, and in 1846 finished a bust which was purchased by the city of Charleston and placed in the city hall, where it was greatly admired. The city also presented Mr. Mills a gold medal. After this he executed several busts of distinguished persons in South Carolina, which increased his reputation. In the mean time some friends offered to furnish the means to enable him to go to Italy to study his art. He eagerly accepted their assistance; but while visiting Washington in 1848, to examine works of art there, prior to his voyage, he was requested to furnish a design for the proposed equestrian statue of Gen. Jackson. The proposition took Mills by surprise. He had never seen an equestrian statue in his life; but, convinced on reflection of his ability to execute the work, he abandoned his purpose of going to Italy, returned to Charleston, and completed the model in 8 months. The committee at Washington accepted it, and made a contract for the execution of the work. On ground belonging to the government in Washington, near the treasury department, Mr. Mills erected a small frame building for a residence and workshop. He first made a full-sized model of the group in plaster, which occupied him two years, and, being exhibited to the public, excited much admiration. The horse rested upon the hind feet, and was perfectly balanced. This attitude had never been so employed before; critics, artists, and scientific men declared that it could not stand; and men of established reputation in science said that success in a bronze statue according to the model was a physical impossibility. Mr. Mills however resolved to have the statue cast. He applied to several large foundries in Pennsylvania, but ascertained that there was not one large enough to execute the work. He therefore built a foundry himself on an entirely original plan, with neither chimney, smoke stack, nor draft of any kind. It was not only declared utterly unfit for the purpose, but absolutely ridiculed. Mr. Mills tested it, however, and found that with comparatively little fuel he could generate the most intense heat. Having thus triumphed over formidable difficulties, he could find no workmen who understood casting so large a mass as his statue, and had therefore to learn the practical business of casting himself. After numerous trials, interrupted by unforeseen accidents, he succeeded, in Oct. 1852, in producing a perfect cast of his work. On Jan. 8, 1853, the anniversary of the battle of New Orleans, the statue was inaugurated. It stands in Lafayette square, near the president's house. It was completed at a cost of \$7,000 to Mr. Mills, but immediately after its inauguration congress made him an appropriation of \$20,000. At the same session the sum of \$50,000 was appropriated for a colossal equestrian statue of Washington, to be executed by him. The sculptor now purchased ground two miles from Washington city, where he be-

complete foundery. He there designed and recuted the Washington statue upon a plan entirely different from that of Jackson. It is somewhat larger, and represents a scene in the battle of Princeton, where Washington, after vainly trying to rally his troops, puts spurs to his horse and dashes up to the cannon's mouth. The steed suddenly stops, and is in the act of recoiling, his head thrown up, and his left foot raised. This statue was inaugurated in Washington, on Feb. 22, 1860. Mr. Mills's next employment was the casting of a colossal statue of Liberty, from a design by Crawford, intended to crown the dome of the capitol.

MILLS, SAMUEL JOHN, jr., an American Congregational clergyman, born at Torrington, Conn., April 21, 1783, died at sea, June 16, 1818. His father was a Congregational minister. He entered Williams college in 1806. In Sept. 1808, a society was formed in the college whose object was stated to be "to effect, in the persons of its members, a mission or missions to the heathen;" and the first name appended to its constitution was that of Mr. Mills. This was the first foreign missionary organization in America. He was graduated in 1809, and spent some months at Yale college, partly to study theology, and partly to interest some of the students there in the cause of missions. In the spring of 1810 he entered Andover theological seminary, where he soon found others interested in the subject; and on June 28, in connection with Messrs. Adson, Nott, and Newell, he presented a memorial to the general association of Massachusetts, then in session at Bradford, stating their views and wishes, and asking advice. This memorial led directly to the formation of the American board of commissioners for foreign missions. In 1812, soon after he was licensed, he went, in company with the Rev. J. F. Schermerhorn, on a missionary tour to the southwestern states, under the combined patronage of the Connecticut and Massachusetts missionary societies. On this tour he preached and organized Bible and other religious benevolent societies. In July, 1814, he made a second tour to the same region, accompanied by the Rev. Daniel Smith. He was ordained June 21, 1815, and for the next two years passed most of the time in Albany, New York, Philadelphia, and Washington, in the promotion of the great enterprises on which his heart was set. Among the fruits of these two years' labor may be traced directly or indirectly to him the establishment of the foreign mission school at Cornwall, Conn., the organization of the American bible society and of the united foreign missionary society, afterward merged in the American board, the first movement for city missions in New York, the establishment of a school for the education of colored preachers and teachers at Parsippany, N. J., by the synod of New York and New Jersey, and the organization of the American colonization society. Almost immediately on its organization, the colonization society sent Mr. Mills and the Rev. Ebenezer

Burgess to Africa, to select a site for a colony. They sailed first for England, Nov. 16, 1817, to confer there with the friends of African colonization, and in February following embarked at London for the African coast, where they spent two months. Having fulfilled the object of their mission, they sailed on their return voyage, May 22, 1818, and Mr. Mills died on shipboard before reaching home.—See "Memoirs of Samuel J. Mills," by the Rev. Gardiner Spring (8vo., New York, 1820).

MILLSTONE, a hard and rough stone in one or many pieces, formed into cylindrical shape, from 8 to 7 feet in diameter, and 8 to 18 inches thick, and used together with another of the same size and shape for grinding grain, &c. The lower stone is firmly fixed in its bed, and is known as the "bedder." The upper one, called the "runner," is suspended over this so as to revolve with its lower face exactly parallel to the upper face of the lower stone, and more or less close to it according to the required fineness of the flour. The grain is admitted through a hole in the centre of the upper stone from the hopper above; and as it is ground the flour escapes round the outer edges. Horizontal grooves are cut on the face of each stone, radiating from near the centre to the periphery, and one edge of these grooves is sharp and perpendicular to the face. The two stones being cut alike, when they are turned face to face these edges work against each other and crush the grain between them. The flat portions each side of the grooves are called "lands." The best millstones are made of buhrstone. (See BUHRSTONE.) They continue in use for many years, sometimes as many as 20, the edges being occasionally recut. Very hard granite is also used for millstones, and the Shawangunk sandstone has long been quarried at Esopus, N. Y., for the same purpose.

MILLSTONE GRIT, a formation of coarse white sandstone, chiefly composed of quartz pebbles, found at the base of the coal measures in the United States and also in Great Britain. Its name is derived from the use to which it has been extensively applied in the latter country. (See ANTHRACITE.)

MILMAN, HENRY HART, D.D., an English clergyman and author, born in London, Feb. 10, 1791. He is the youngest son of Sir Francis Milman, physician to George III., and was educated at Eton and at Brasenose college, Oxford, where he obtained a fellowship. His literary career commenced in 1815, with the publication of "Fazio," a tragedy performed successfully at Covent Garden; and in 1817 he took orders and was presented to the vicarage of St. Mary's, Reading. In 1818 he published "Samor, Lord of the Bright City, an Heroic Poem," founded on passages in the legendary history of Britain, which was followed in 1820 by his most successful production in verse, "The Fall of Jerusalem," a dramatic poem. In the succeeding year he was appointed professor of poetry in the university of Oxford, and pub-

lished 8 other dramatic poems, "The Martyr of Antioch," "Belshazzar," and "Anne Bolleyn." After a considerable interval appeared his "Sermons at the Bampton Lecture" (8vo., 1827), followed in 1829 by a "History of the Jews" (8 vols. 18mo.), published anonymously; and in 1840 he published a collected edition of his poetical works. In the same year he produced one of his most elaborate works, a "History of Christianity from the Birth of Christ to the Abolition of Paganism in the Roman Empire" (8 vols. 8vo.), and in 1854-'7 a "History of Latin Christianity, including that of the Popes, to the Pontificate of Nicholas V." (6 vols. 8vo.), which is designed as a continuation of the former, although it is also a complete work. He has prepared a sumptuously printed and illustrated edition of Horace (8vo., 1849), with a life of the poet and criticisms on his writings, and an annotated edition of Gibbon's "Decline and Fall of the Roman Empire," preceded by a life of the historian. Numerous articles attributed to his pen have appeared in the "Quarterly Review." He at present holds the office of dean of St. Paul's, to which he was preferred in 1849.

MILNE, WILLIAM, an English missionary, born in the latter part of the last century, died in China in 1822. In 1818 he visited China, under the auspices of the London missionary society, and during the next two years travelled extensively through that country, Malacca, and the chief islands of the Indian archipelago, distributing many thousand tracts and Testaments among the natives. He subsequently established himself in Malacca, and founded a missionary station, which became one of the most important in eastern Asia. He continued to circulate the Scriptures, and also superintended the publication of religious works and of a monthly magazine. In 1817 he was again in China, where he projected the plan of an Anglo-Chinese college, aided in translating the Old Testament into Chinese, and originated the "Indo-Chinese Gleaner," a quarterly publication. He died in the midst of his labors. He is the author of a "Retrospect of the Protestant Mission to China."

MILNE-EDWARDS, HENRI, a French physician and naturalist, born in Bruges, Belgium, in 1800. He studied medicine in Paris, and devoted himself principally to physiological pursuits. After occupying the chair of natural history at the lyceum of Henry IV., he was intrusted with similar duties at the museum and the faculty of sciences, of which he is at present dean. In 1838 he succeeded Ouvier in the anatomical and zoological section of the academy of sciences. His publications comprise "Anatomical Researches concerning the Crustacea" (1828), for which he received a prize from the academy of sciences; "Manual of Materia Medica" (1832); "New Formulary of Practice for Hospitals" (4th ed., 1840); "Course of Natural History" (1834), in conjunction with Achille Comte; "Elements of Zoology" (1834-'5), re-

vised and republished in 1851 under the title of "Elementary Course of Zoology;" "Natural History of the Crustacea" (8 vols. 8vo., 1837-'41); "Lessons on the Physiology and Comparative Anatomy of Man and Animals" (1855-'7); a new edition of De Lamarck's "Natural History of the Invertebrata" (11 vols. 8vo., 1836-'45); and numerous articles contributed to scientific periodicals and cyclopædias.

MILNER, JOHN, an English Roman Catholic divine and antiquary, born in London in 1752, died at Wolverhampton in 1826. He completed his education at Douai, and was appointed pastor of a Roman Catholic congregation at Winchester. In 1790 he was admitted a member of the royal society of antiquaries, and in 1803 was created vicar apostolic of the midland district with the title of bishop of Castabala. His most important works are: "The End of Religious Controversy;" "History, Civil and Ecclesiastical, and Survey of the Antiquities of Winchester;" and "Treatise on the Ecclesiastical Architecture of England during the Middle Ages."

MILNER, JOSEPH, an English divine and historian, born near Leeds, Jan. 2, 1744, died in Hull, Nov. 15, 1797. He was graduated at Catharine hall, Cambridge, in 1766, and after taking orders became head master of the grammar school and lecturer of the principal church of Hull. The most important of his works is his "History of the Church of Christ from its Foundation to the 13th Century" (3 vols. 8vo., London, 1794). It was continued by his brother to the reformation. A complete edition of his works, with an account of his life, was published by his brother in 1810, in 8 vols. 8vo.—ISAAC, brother of the preceding, born near Leeds in 1751, died in London, April 1, 1820. On the death of his father he left school, and worked for a time in a factory; but his brother, on being appointed head master of the grammar school at Hull, employed him as an assistant. In 1770 he entered Queen's college, Cambridge, where in 1774 he became senior wrangler, and in 1775 was elected a fellow. In 1783 he was named Jacksonian professor of experimental philosophy, in 1788 became master of Queen's college, and in 1791 was created dean of Carlisle. At Cambridge he formed an intimacy with William Wilberforce which endured through life, and he died in his house. His principal works are: a continuation of his brother's "History of the Church of Christ," "Animadversions on Dr. Haweis's Church History," "Essay on Human Liberty," and 2 volumes of "Sermons."

MILNES, RICHARD MONCKTON, an English author and statesman, born in Yorkshire in 1809. He was graduated at the university of Cambridge in 1831, and subsequently made a tour in southern Europe, and wrote "Memoirs of a Tour in Greece," published in 1841. In 1837 he entered parliament as member for Pontefract, which constituency he still continues to represent. As a legislator he has pursued an independent course, although his politics incline to those of the liberal conservative

marty. He has advocated popular education, religious equality, and measures for the reformation of criminals, and has proved himself a warm friend of the people of Italy in their struggles for independence. He has written 4 volumes of poems marked by taste and fluency of diction, entitled "Poems of Many Years," "Memorials of Many Scenes," "Poems Legendary and Historical," and "Palm Leaves: Eastern Poems;" and is the author of an appreciative and judicious memoir of John Keats, whose letters and literary remains he edited in 1848. He has also published several pamphlets and speeches on political topics, including "Thoughts on Party Politics," "Real Union of England and Ireland," "Events of 1848, especially in their relation to Great Britain," &c., and has contributed articles to the "Westminster Review" and other periodicals.

MILNOR, JAMES, D.D., an American clergyman, born in Philadelphia, June 20, 1778, died in New York, April 8, 1844. After spending a brief period at the university of Pennsylvania, he began the study of law in his native city in 1789, was admitted to the bar in 1794, and practised his profession at Norristown till 1797, when he removed to Philadelphia, where he served in several public stations. In 1810 he became a representative in congress, where he opposed the war of 1812 with zeal and ability. The parents of Mr. Milnor belonged to the society of Friends; but having married a lady belonging to the Episcopal church, and being desirous of devoting himself to the preaching of the gospel, he prepared himself for the ministry of the Episcopal church, and was ordained by Bishop White, Aug. 14, 1814. Having served in Philadelphia for a year, he was called in 1816 to St. George's church, New York, where he remained till the close of his life. Dr. Milnor's labors were abundant, not only in the discharge of his parish duties, but also in connection with the American Bible and Tract societies, and other philanthropic and charitable institutions in New York; and he has left behind him the memory of a man who possessed excellent sense and sound judgment. A few occasional sermons and addresses are all of Dr. Milnor's writings that were committed to the press.—See "Memoirs of the Life of James Milnor," by the Rev. J. S. Stone, D.D. (8vo., New York, 1848).

MILO (anc. *Melos*), an island of volcanic formation in the Grecian archipelago, and one of the Cyclades, belonging to the kingdom of Greece, lying about 65 m. E. from the coast of the Morea, in lat. 36° 40' N., long. 24° 28' E.; length 14 m., breadth 8 m.; area, 65 sq. m.; pop. about 4,000. It has on its N. coast one of the best harbors in the Levant. The soil of the valleys is fertile, producing corn, cotton, fruit, oil, and wine. There are hot mineral springs, and mines of sulphur, vitriol, and alum. Mt. St. Elias is about 2,500 feet above the sea. Milo, the capital, now almost depopulated, is situated on the E. coast, near the site of the

ancient metropolis, extensive ruins of which remain. Melos was first colonized by the Phœnicians, and afterward by the Lacedæmonians. It was rich and populous, but was ruined by the Peloponnesian war, during which the capital was captured by the Athenians, its adult males put to death, and its women and children carried off as slaves, 416 B. C. The principal relics of antiquity at Milo are tombs and subterranean vaults, some of which contain 15 or more sarcophagi. The celebrated statue of the Venus of Milo, which is at present in the Louvre, was found in 1820 in the vicinity of Milo, together with 8 statues of Hermes.

MILO, or MILON, a Greek athlete, born in Crotona, in Magna Græcia, flourished in the latter part of the 6th century B. C. His extraordinary physical strength gave him the victory in wrestling 6 times at Olympia, and as often in the Pythian games. He is stated to have carried a 4-year-old heifer on his shoulders 4 times around the Olympic race course, and then to have eaten the whole of it in one day. In 511 he was appointed to command an army against the Sybarites. He was worsted by the agility of his adversary in his 7th Olympic struggle. Enfeebled by age, it is said, he attempted to tear asunder with his hands a forest tree partially split by wood cutters; he was caught and held fast by the closing of the fissure, and was devoured by wolves.

MILO, TITUS ANNIUS PAPIRIANUS, a Roman tribune and demagogue, born at Lanuvium in the earlier part of the 1st century B. C. In 57 he filled the office of plebeian tribune. At that period Clodius, at the head of a band of desperadoes, controlled the destinies of Rome, burning temples, attacking the houses of private citizens, shedding the blood of freemen in the streets, dispersing the comitia by violence, and trampling under foot all laws. Milo, who was little better than Clodius, but desirous of retrieving his ruined fortunes by an alliance with the aristocrats, temporarily restored order, after which Cicero was recalled from exile. Clodius, who had been the author of Cicero's banishment, now assailed his person and property, and would have sacrificed him had not Milo come to his aid. The followers of Milo and Clodius now daily fought in the streets. The rival chiefs and their retainers met at Bovillæ, on the Appian way, in Jan. 52, and in the fray Clodius was slain. Milo was brought to trial, and Cicero, his advocate, was so intimidated that he did not venture to deliver the oration he had prepared; his client was convicted and went into exile to Massilia, whither Cicero sent him soon after a copy of the undelivered speech. On perusing it, he is said to have exclaimed: "How fortunate it is that this oration was not delivered, for then I should have been acquitted, and have never known the delicious flavor of these Massilian mullets." Milo remained in exile till 48 B. C., when he returned to Italy to aid Marcus Cælius in resuscitating the republican party, but was defeated and slain in Lucania.

MILOSH, prince of Servia. See **ОБЗЕРКОВИЧ**.

MILTIADES, an Athenian general and statesman, who flourished at the beginning of the 5th century B. C. He was of a noble Athenian family, son of Cimon, and nephew of the elder Miltiades, who was prominent in Athens in the time of Pisistratus, and was also the founder of a despotism in the Thracian Chersonesus. The younger Miltiades was sent out about 516 B. C. to take possession of his uncle's inheritance. There, in order to secure his position, he imprisoned the chief men by stratagem, employed a force of mercenaries, and married the daughter of a Thracian prince. In 518 he joined Darius Hystaspes on his expedition against the Scythians, and remained with the Ionians to guard the bridge over the Danube while the Persian army advanced to the north. When the appointed time had passed, and nothing had been heard from Darius, he warmly urged the destruction of the bridge and the abandonment of the Persians, but was overruled by the Ionian leaders, who maintained their own ascendancy by Persian support alone, the feeling of the population being everywhere against them. Had his opinion prevailed, says Grote, he would thus have inflicted a more vital blow on Persia than afterward by the victory of Marathon. He remained in the Chersonese till about 498, with the exception of a brief interval during which he was obliged to retire, either in consequence of a Scythian invasion or from the temporary enmity of Darius. His only achievement during this period was the conquest of Lemnos and Imbros, which probably took place while the Persians were occupied with the Ionic revolt (between 502 and 494). He thus drew upon himself the hostility of Darius, was driven from the Chersonese at the close of the Ionic war, and on his flight to Athens narrowly escaped capture by the Phœnician fleet. He was immediately brought to trial by the Athenians for alleged despotism in his administration of the Chersonese, but was honorably acquitted, and his fame as the conqueror of Lemnos secured his election as one of the 10 generals at a time when the Persian armament under Datis and Artaphernes was known to be approaching Greece. While the generals were equally divided as to whether to meet the enemy in the field or to defend the city behind its walls, the arguments of Miltiades persuaded the polemarch Callimachus to give his casting vote in favor of immediate attack, and thus brought on the battle of Marathon. Though the other generals surrendered to him their days of command, it is said that he waited till the day of his own regular turn before he engaged the enemy, and achieved the most memorable victory in the history of Greece. The admiration of him by his countrymen was now unbounded. At his request, he was intrusted with an armament of 70 ships, placed at his sole discretion, no other man knowing its destination. He sailed against the island of Paros for the purpose of gratifying a private animosity, and ravaged the island, but failed to

capture the town. Being seized with a panic while visiting a priestess on a superstitious errand, he dangerously strained or bruised his thigh by falling, and raised the siege. On his return to Athens he was impeached and condemned to pay a penalty of 50 talents, and soon after died of his wound. According to Cornelius Nepos and Plutarch, he was imprisoned after having been fined, but this is not stated by Herodotus. The fine was afterward paid by his son Cimon.

MILTON, JOHN, an English epic poet, born in London, Dec. 9, 1608, died there, Nov. 8, 1674. His birthplace, in old Bread street, was almost beneath the bells of Bow church, within hearing of the roar of Cheapside, near the Mermaid tavern, the resort of the Elizabethan wits, and not far from old St. Paul's and the tower. His father, the son of an under-ranger in the royal forest of Shotover, Oxfordshire, had at an early age been disinherited for abandoning the Catholic faith, and had betaken himself to the profession of scrivener or copying lawyer, in which he was so successful as ultimately to retire from business with an independence. Though a serious man, and inclined to Puritanic habits, he had cultivated literature in his leisure, and was so skilled in music that he holds a respectable rank among the contemporary composers of madrigals, songs, and psalms. Milton thus not only received in boyhood the devout and dutiful training of a Puritan family, but was also taught the art and science of music, for which nature had granted him the ear and the passion, and became an accomplished organist. It is noticed that whenever in his writings he speaks of music, he is technically always strictly correct. His father secured for him the best educational advantages; and both as a boy and a man Milton was severely and constantly studious. He was still under the care of a private tutor, Thomas Young, a graduate of one of the Scotch universities, when, being scarcely 12 years old, he was sent to the school of St. Paul's, founded by Dean Colet in 1512, and then in the highest repute. His own testimony is confirmed by that of his brother Christopher, reported by Aubrey, that even at that age he seldom retired to rest from his studies till after midnight. There began his memorable friendships with Diodati and Gill, the latter just beginning his career in holy orders. He was able to compose Latin prose and verse with ease and elegance, was familiar with Greek and Hebrew, and had "no mean apprehension of the sweetness of philosophy," when at the age of 16 he was entered as a pensioner at Christ's college, Cambridge. Though destined from childhood to the church, he resolved early in his university career upon a life of continued study, with no professional aim whatever, but with a view to the ultimate display of his powers in authorship. "For 7 years," he says, "I studied the learning and arts wont to be taught, far from all vice, and approved of all good men, even till having taken

that they call the master's degree, and that with praise." It is certain, however, that he led a life of singular intellectual independence, that he did not conceal his disinclination to the scholastic sciences that were still in vogue, that certain haughtiness of manner and obstinacy of temper made him sometimes unpopular within his college, and that he was for a period at variance with the authorities, and incurred the sentence of rustication. There is not sufficient evidence for the supposition of Dr. Johnson that he was one of the last students in either university who suffered the public indignity of corporal correction. His disgrace must have been brief, since he took both degrees at the regular times. Though in his range of study he broke from the bondage of the mediæval *trivium* and *quadrivium*, yet his Latin productions and elegies gave a new interest to the university ceremonies, and redounded to the credit of master and fellows. A solemn and almost austere demeanor, a conviction of superior powers, a conscious devotion to great and noble things, and a singular moral fastidiousness marked his character. His personal beauty is uniformly mentioned by those who describe his youth as very remarkable. His light brown hair, parted in the middle, fell in curls upon his shoulders; the expression of his clear gray eyes was serene and thoughtful; and, though he excelled in manly exercises, his fair complexion, slight figure, and innocent life caused him to be styled by his fellow collegians "the lady of Christ's." On quitting the university in 1632, he took up his abode in the village of Horton, Buckinghamshire, whither his father had retired from London. There he spent the next 5 years in "a ceaseless round of study and reading," varied only by occasional visits to the metropolis for the purpose of procuring books or taking lessons in music and mathematics. He stored his mind with the noblest passages in the ancient and the Italian classics, and the minute accuracy of his scholarship is proved by his marginal notes on Euripides, while both his prose and verse abound in demonstrations of the great range and variety of his learning. In this happy interval between the enforced studies of the university and the duties of public life, he wrote his exquisite minor poems, the "Sonnet to the Nightingale," the companion pieces "L'Allegro" and "Il Penseroso," the masques of "Arcades" and "Comus," and the elegy of "Lycidas." None of his other compositions are so tranquil and happy in tone, or indicate so distinctly his mastery of the lighter graces of poetry. They are filled with rural imagery, delicate fancies, lyrical allusions, and sensuous descriptions. The massive and austere character abnegated in his earlier life the passions incident to the poet's temperament, and they appear in his poems only when transmuted into a pure essence. He celebrates the diviner and grander parts of our nature rather than its human frailties. There is no humor and no love even in the polished pro-

ductions of his studious leisure at Horton, which are constantly pervaded by the intellectual greatness, the vastness of conception, the remote associations, and the exquisite choice of language that mark more decisively his later writings. The themes, the fancies, and the idyllic treatment strikingly contrast with the poems which he produced after 20 years of conflict in public life. On the death of his mother in 1637 he obtained his father's permission to fulfil a cherished project of travel on the continent, especially in Italy; and he set out in the following year as an English gentleman, furnished with letters of introduction, and attended by his own servant. In Paris he was welcomed by the English ambassador and introduced to Grotius; in Florence he remained 2 months, and was received into the literary academies, before which, according to the custom, he gave evidence of his learning, and recited some of his Latin poems and 8 Italian sonnets, which won the encomiums of Italian wits and scholars; in Rome he made another stay of 2 months, protected by Lucas Holstein, the librarian of the Vatican, and by Cardinal Barberini, and chiefly delighted by several opportunities of hearing Leonora Baroni sing; and in Naples he became acquainted with the venerable Giovanni Battista Manso, marquis of Villa, the friend and biographer of Torquato Tasso, who accompanied him to the viceroy's palace and other places of interest, and apologized for showing no further attentions because his guest spoke with so little reserve on matters of religion. He abandoned his purpose of proceeding to Sicily and Greece, and thus exploring the principal classic lands, on receiving tidings of the impending rupture between the king and people in England; since he deemed it disgraceful to be pursuing his own gratification abroad while his countrymen were contending for liberty. He returned by way of Rome, where he again remained 2 months, and, though warned of Jesuitical plots, openly "defended the reformed religion in the very metropolis of popery" without fear or molestation. He proceeded thence to Florence, crossed the Apennines to Bologna, delayed a month in Venice, whence he sent his collection of books and music by sea to London, reached Geneva by way of Verona, Milan, and Mt. St. Bernard, and taking his former route through France arrived in his native land in Aug. 1639, after an absence of 15 months. The effect of his intercourse with eminent continental scholars and authors had been to quicken his literary ambition, and to strengthen his inward prompting that by labor and intent study he might write something which mankind would not willingly let die. The fall of man had not yet occurred to him as a theme, but he had fully determined to spend his strength on a poem of the highest order, either epic or dramatic, the subject perhaps to be the legend of King Arthur, or some other in ancient British history as chronicled by Geoffrey of Monmouth. His meditations were interrupted by the civil com-

motions, and by a period of 20 years during which the literature of England was almost exclusively polemical. He consented "to lay aside his singing robes," "to leave a calm and pleasing solitariness, fed with cheerful and confident thoughts," and "to embark in a troubled sea of noises and hoarse disputes," supposing that within one or two years the storm would be appeased; but during the whole splendid and vexed era of Puritan supremacy in England, with the exception of a few sonnets, he appears only as a polemical prose writer and champion of the revolution. During his absence his father had broken up his household at Horton and made his residence with his younger son Christopher in Reading. Milton therefore hired apartments and subsequently a house in the city for himself and his library, and received his two young nephews Edward and John Phillips, sons of his sister Anne, to board with him as pupils. A few more pupils, sons of intimate friends, were afterward admitted; and while pursuing his private studies he devoted a part of his time to their education after a peculiar system of his own. He was thus occupied with studying and teaching, when the aspect of public affairs called forth his first pamphlet. The long parliament met in 1640; Laud and Strafford, respectively the upholders of despotism in church and state, were overthrown; the danger from free speech was removed; and the circumstances of the time, when the government of England was nearly as much a matter of fundamental discussion as that of France is in a revolutionary epoch, offered an invitation to thinkers. Prominent among topics of public interest was that of church reform. In the controversy on this subject Milton engaged by publishing a treatise entitled "Of Reformation, touching Church Discipline in England, and the Causes that hitherto have hindered it" (1641), a vehement attack on the episcopal form of government. In the same year Bishop Hall of Norwich, at the request of Laud, undertook a defence of episcopacy, and was answered by a combination of 5 Puritan ministers under the title of Smectymnus, a word composed of the initials of their names. Archbishop Usher immediately replied to the Smectymnians, and Bishop Hall published a defence of himself. Milton esteemed Usher superior to his Puritan antagonists in learning, and Hall superior to them in wit and literary talent, and anticipated the triumph of the prelates unless he came to the aid of his friends. He therefore published two pamphlets in answer to the former, entitled "Of Prelatical Episcopacy" and the "Reason of Church Government urged against Prelaty," and a tract in the form of a dialogue entitled "Animadversions" upon Bishop Hall's defence. The last drew forth an anonymous and slanderous response, attributed to a son of Bishop Hall; and the controversy was concluded by Milton's "Apology for Smectymnus," in which in an eloquent self-vindication he gives an interesting account of his education, studies, and

pursuits, and a eulogy of the long parliament. The question in dispute, the divine origin and authority of episcopacy, had meantime been practically settled by the government. In 1643 he was resting from controversy, occupied with his pupils, and meditating the great poetic work to which he wished to transfer all his mental power and industry. But in the midst of civil war and of epical contemplations he contracted a marriage as singular as any in the strange series of the loves of the poets. "About Whitsuntide," says Phillips, "he took a journey into the country, nobody about him certainly knowing the reason, or that it was more than a journey of recreation. After a month's stay, before he returns a married man, who set out a bachelor; his wife being Mary, the eldest daughter of Mr. Richard Powell, then a justice of the peace of Forest Hill, near Shotover, in Oxfordshire." It appears that his father had made a formal memorandum to him of a certain sum due from Mr. Richard Powell; that the larger part of this debt was never paid; that his numerous rides to Forest Hill in quest of money had resulted only in a matrimonial engagement; that he never received a shilling of the fortune of £1,000 which was promised with his wife; and that he encountered "a mute and spiritless mate" where he had expected "an intimate and speaking help." Moreover, it was a marriage amid civil conflict between a renowned parliamentarian and a lady of a royalist family. She remained only one month with her husband, and then accepted an invitation from her family, probably suggested by herself, to go back and spend some time in the country; and at a secure distance she treated both the letters and messengers of the poet with contempt, and absolutely refused to return. The pleas suggested on her side are that she was used to company and merriment, and disliked Milton's "spare diet and hard study;" the poet's chief and singular ground of complaint was that his wife would not talk; it is probable that they simply disliked each other, and that nothing but an imprudent marriage suggested to him "the pious necessity of divorcing," even in cases that depend upon "utterless facts." Milton was not a man to tolerate an insult in so delicate a matter; and he immediately came to the conclusion that other reasons, besides those legally admitted, might be sufficient for the dissolution of the nuptial tie, and determined publicly to argue his case. With his intellectual clearness and boldness which were his special characteristics, he pushed his ideas of civil and ecclesiastical liberty into the realm of the domestic circle; and he resolutely advanced the doctrine that moral incompatibility, as well as conjugal infidelity justifies divorce. It should be noticed that he does not disagree with his opinion of the natural inferiority of women. His publications on this subject are: the "Doctrine and Discipline of Divorce restored to the Good of Both Sexes from the Bondage of Common Law" (2 editions in 1644); the "J. J."

ment of Martin Bucer touching Divorce" (1644), in which he shows that a celebrated contemporary of King Edward VI. had been of the same opinion as himself; "Tetrachordon, or Expositions upon the four chief Places in Scripture which treat of Marriage or Nullities in Marriage" (1645); and "Colasterion: a Reply to a Nameless Answer against the Doctrine and Discipline of Divorce" (1645). His efforts for a change of law were a total failure, but he retained his opinions till the close of his life. The discussion of the subject which he raised was no less intolerant and impatient than that on episcopacy had been, and during its progress he was summoned to the bar of the house of lords, but was honorably dismissed. Meantime he had published his tractate "On Education," only the theoretical views of which are important, and had addressed to the parliament the noblest and most useful of his compositions in prose, the "Areopagitica, a Speech for the Liberty of Unlicensed Printing" (1644). It was a plea for the freedom in literature which he had previously maintained in civil and social life; but though it contains his finest passages of prose eloquence, it was not successful in its aim of abolishing the newly established censorship. In 1645 appeared the first edition of his poems, containing in a small volume all that had yet been written. In the same year a reconciliation was effected between him and his wife. She returned to his house, and her whole family were generously entertained by him for several months. After their departure, his abode, says Phillips, "looked again like a house of the Muses." He lived successively in the Barbican and in Holborn, and was occupied with writing his history of England. The execution of King Charles (Jan. 30, 1649) aroused throughout Europe a feeling of horror and indignation, and created a reactionary tendency even among the partisans of the revolution. To justify the event and compose the startled minds of the people, Milton wrote the "Tenure of Kings and Magistrates," published within a month after the death of the king, in which he undertook to prove that subjects have a right to depose or put to death a wicked monarch. He also published "Observations" on the articles of peace which the earl of Ormond had lately concluded in the king's name with the Irish Catholics. Upon the establishment of the commonwealth, presided over by a council, the Latin was fixed upon as the official language of intercourse with foreign states. To Milton, in view both of his scholarship and his services, was offered the position of secretary for foreign tongues; and 16 letters and other documents first published by the Camden society in 1859 confirm all previous impressions of his skill in Latin composition, and of the eloquence, energy, and dignity he gave to the political despatches of the commonwealth. He vindicated the freedom of England on the seas, protested against the persecution of the Waldenses by the duke of Savoy, and expounded to Europe the position

and policy of the new government. The *Eikon Basilike* was passing through numerous editions, and winning popular sympathy for the "royal martyr," and he therefore prepared a counteractive under the title of *Iconoclastes* (1649). Claude de Saumaise (Salmasius), one of the most distinguished contemporary scholars, was instigated by Charles II., then a refugee in Holland, to compose an elaborate defence of the inviolability of kings, and especially of royalty in England, in a treatise worthy to be submitted to the learned of Europe. The name of the author was sufficient to secure fame and extended influence to his work, and the council immediately made an order "that Mr. Milton do prepare something in answer to the book of Salmasius." This was the occasion of his first "Defence for the People of England" (1650), in which he assailed at once the philosophy and Latinity of his opponent, and surpassed him in the power of scholastic vituperation. It was deemed a triumph, and he received the thanks of the council and the congratulations of all the foreign ministers in London. His eyesight had been decaying for several years, and his physicians had informed him before he undertook this defence that total blindness was threatened. He, however, regarded the task as a sacred duty, and it hastened the malady, the "drop serene" (*gutta serena*), as it is termed in his plaintive account of it. Before 1658 he was completely blind, though his eyes were perfectly clear, and without mark, speck, or any disfigurement whatever. He had already removed to the house in Petty France, opening into St. James's park, in which he remained till the restoration, and which was afterward occupied by Hazlitt. In 1652 appeared a work entitled *Regii Sanguinis Clamor ad Cælum*, written by Dumoulin, a Frenchman resident in England, but attributed to Moore (Morus), a Scotchman resident in France, abounding in calumnious invective against Milton personally. This occasioned his *Defensio Secunda* (1654), a noble defence of his own conduct, a vindication of the parliament, and a merciless retaliation for the scurrilities of his antagonist. The dispute was prolonged by two additional pamphlets on each side. Milton continued to write many of the more important state papers until the year of the restoration, and was also occupied with his history of England, with framing a body of divinity, and perhaps with the composition of his great poem, the subject of which he had at length determined. He also opposed to the last in divers tracts and letters the return of the monarchy. During the 20 years in which he had been thus diverted from "the laureate fraternity of poets" and from "the shady places of philosophy," he had been the foremost literary champion of the principles of English liberty, then struggling for recognition. His polemical writings abound in passages of the finest declamation, marked by a peculiar majesty of diction, and by a sustained and passionate magniloquence. The political theory which he advanced was in

some respects peculiar to himself. He advocated a free commonwealth, without a sovereign or a house of lords. The government should be intrusted to a general council of ablest men, chosen by the nation, and he opposed the co-existence of any popular assembly. He would not even have the members of the council chosen directly by a popular vote, but recommended three or four "sifting and refining" processes. After the restoration, a proclamation was issued for the arrest of Milton, and two of his books were publicly burned. He lived in concealment till the passing of the act of indemnity, without his name among the exceptions, placed him in safety. His first wife had died in 1652 or 1653, leaving him 8 little girls; he married a second time in 1656, but his wife, whose memory is embalmed in one of his most beautiful sonnets, survived only 15 months; and he entered a third time into the matrimonial state after a widowhood of 8 years. The last was a marriage of convenience, arranged by a friend, because his daughters had ceased to treat him with kindness. They, however, lived in his house 5 or 6 years longer, in constant quarrel with their stepmother. Unsubdued by pain, obloquy, and blindness, amid domestic infelicities and the profligacy of the era of the comic dramatists, and witnessing the public defeat of the principles which he had represented, he meditated and dictated the poems of "Paradise Lost" and "Paradise Regained." According to Ellwood, the former was completed and the latter was commenced at Chalfont, whither Milton retired from London during the prevalence of the plague in 1665. "Paradise Lost" was sold to Samuel Simmons, bookseller, April 27, 1667, for £5 in hand, and a promise of the same sum on the sale of the first 1,800 copies of each edition, none of which was to exceed 1,500 copies. The second payment was received in 1669, the second edition was issued in 1674, the third in 1678, and in 1681 Milton's widow gave up to Simmons all her interest in the work for the sum of £8. "Paradise Regained" appeared in 1671, in the same volume with the drama of "Samson Agonistes." A second and enlarged edition of his minor poems was published in 1678. His principal later prose publications were the "History of Britain" (1670), down to the Norman conquest, containing many of the early traditions, much of which had been written before the restoration; a tract entitled "Of True Religion, Heresie, Schism, Toleration, and what best Means may be used against the Growth of Popery" (1678), in which he urges absolute toleration for all Protestant sects, but denies it to Roman Catholics; a short Latin grammar (1661); a compendium of logic (1672); and his Latin epistles and oratorical exercises in the university (1674). He left in manuscript a Latin treatise on Christian doctrine, which had been unsuccessfully offered to Elzevir for publication. Two years after his death it came into the hands of one of the English secretaries of state, by whom it was deposited in the state

paper office, where it remained unknown till 1828, when it was accidentally discovered. It was immediately translated, and edited by C. R. Sumner, D.D., afterward bishop of Winchester, and it completely establishes Milton's Arianism, which had previously been suspected from passages in "Paradise Lost." Its heterodoxy was doubtless the reason why it was first offered to a Dutch publisher, and afterward withheld from the public. In his last years he was afflicted by the gout, which, according to Aubrey, "struck in" and caused his death. He died calmly and without pain, and his remains were laid beside those of his father in the church of St. Giles, Cripplegate. After his sight failed he had been accustomed to retire at 9 o'clock at night, and lie till 4 in summer, and 5 in winter. Before rising, he often had some one to read to him or to write at his dictation. He studied till 12, with the intervention of breakfast, then exercised for an hour, dined, played on the organ or bass-viol, and resumed his studies till 6, from which hour till 8 he conversed with visitors. He then had olives or something light for supper, smoked a pipe of tobacco, drank a glass of water, and went to bed. His wife, daughters, and other persons were at different times employed to read and write for him. He fancied that "his vein never happily flowed but from the autumnal equinox to the vernal," and was never satisfied with what he wrote in the other half of the year. He attended no church, belonged to no religious communion, and never had social prayers in his family. That he was somewhat haughty and overbearing, and of a severe if not choleric temper, appears from other evidence as well as from passages in his controversial writings; yet his manners were usually urbane and his conversation delightful. As an epic poet, Milton has no rival in the grandeur of his subject and the power of his style. The story of the fall of man, with its scenery of heaven, hell, chaos, and the new earth, exhibiting the daring, suffering, and ruined splendor of a rebellious archangel of surpassing energy and intellect, thwarted in heaven, triumphant over Adam and Eve in paradise, and making the earth from that time for an appointed season a field of battle between the Deity and himself, presents unbounded resources of sublimity. His two greatest creations, the characters of Satan and of Eve, the former the embodiment of intellectual audacity and unprincipled ambition, the latter essentially an abstract woman, yet with all the sweetness and fascination of personality, illustrate at once the compass and the delicacy of the poet's powers. The style of Milton is a rich mosaic. The suggestions culled from his immense reading may be traced not only in similes and metaphors, but in the very texture of his thought and expression. Yet it is also marked by a singular originality, stamped by the capacity and dignity of his own mind. A firm and solemn music pervades it, the stately order of the words has the effect of an incantation, and every line excites the idea of indi-

nite power. More than any other author Milton combines what are usually regarded as the distinctive characteristics of ancient and modern literature. He has the classical simplicity of idea, the rude strength of conception, and he has the romantic complexity and diversity of illustration. The underlying thoughts are few; the adornments are lavish. His principal characters are among the simplest in the whole field of literature, and may be discerned as such through the profusion of superficial imagery. The Swedish poet and critic Tegner thus remarks of him: "His wonderful poem cannot be assigned a place in any of the departments which are usually regarded as the only possible ones for poetic creations. He takes at once into his great ocean the whole of the four paradisaal rivers of poetry, the epic, the lyric, the didactic, and the dramatic. The proper object of the poem is didactic, because it is designed to 'justify the ways of God to man.' It is epic by the greatness of the action and the episodes of the war in heaven. But the action itself is dramatic, both in design and execution, and the main interest from beginning to end dwells about a single great tragic character, the fallen archangel. And the poem is also lyric, not only in single passages, but in general, in its whole tone and expression. Thus then the 'Paradise Lost' forms a species by itself, without a model and as yet without a copy; but to think of rejecting it on this account would be to sacrifice the just rights of genius to the crotchets of the schools. The power with which it seizes on every mind of a deeper and more serious cast only proves the poverty of our ordinary poetic theories."—The principal biographies of Milton are those by Toland, Todd, Symmons, Dr. Johnson, Mitford, Keightley (London, 1859), and Masson (London, 1859 *et seq.*); the last is designed to be an exhaustive account of his life and times. The best edition of Milton's poetical works is Pickering's (8 vols., London, 1851), with a life by the Rev. John Mitford. Among others are those of Bishop Newton (3 vols. 4to., 1749), the first critical edition; Todd, with variorum notes (6 vols., 1801); Hawkins (4 vols., Oxford, 1824); Sir E. Brydges (6 vols., 1831); Keightley (2 vols. 8vo., 1859); and the minor poems by T. Warton (1785). The prose works were first collected by Toland (3 vols. fol., 1697), and have since been edited by Birch (2 vols., 1753) and Charles Symmons (7 vols., 1806); but the only complete edition is in Bohn's "Standard Library" (5 vols. post 8vo., 1852). A concordance to the poems by Prendergast was published in 1858 (1 vol., Madras).

MILUTINOVITCH, SIMON, a Servian poet, born in Sarajevo in Oct. 1791. He is the son of a merchant, received his education at Belgrade and Carlovitz, and from 1806 to 1818 served as a clerk in the department of state at Belgrade. During the troubles which accompanied the Servian insurrection in the following years, he led a homeless and adventurous life and after the restoration of peace found

employment in the family of Prince Milosh. Having gone to see his parents in Bessarabia, and being prevented from returning to his native country by the Greek rising in Wallachia, he accepted a pension from the Russian government, and devoted himself to literary labors. A few years later he went to Leipsic, where most of his works have appeared, and in 1827 to Montenegro, whence he returned to Servia in 1840. His principal works are: *Serbianka* (1826), a collection of heroic poems on the Servian war of independence, numerous incidents of which he had himself witnessed; *Nekolike pjesnice stare* ("Some Old Songs," 1826); *Zorica* ("Dawn," 1827); and "History of Servia in 1818-'15" (1837); beside the "Montenegrine and Herzegovinian Popular Songs," collected and edited by him in the original dialects (1837).

MILWAUKEE, a S. E. co. of Wisconsin, bounded E. by Lake Michigan; area, 240 sq. m.; pop. in 1855, 46,265. It is watered by the Milwaukee, Menomonee, and Root rivers. The surface is undulating, and the soil calcareous and fertile. The productions in 1850 were 61,147 bushels of wheat, 89,299 of Indian corn, 125,584 of oats, and 71,950 of potatoes. There were 5 flouring and grist mills, 4 tanneries, 18 newspapers, 82 churches, and 4,857 pupils attending public schools. The county is traversed by several railroads, centring at the capital, Milwaukee.

MILWAUKEE, the chief city of the state of Wisconsin, and the capital of Milwaukee co., situated on the W. shore of Lake Michigan, in lat. 43° 02' N., long. 87° 54' W., about 40 m. N. from the southern boundary of the state, and 80 m. E. from Madison; pop. in 1850, 20,061; in 1857, 45,000; in 1860, about 60,000. The lake opposite the city makes an indentation in the shore, forming a large and commodious bay, 6 m. wide and 8 m. deep, which is easy of access at all seasons of the year. The Milwaukee river, which flows through the city, and is joined near its mouth by the Menomonee, has been dredged and rendered navigable to the heart of the city by vessels of any tonnage used on the lakes. It is regarded as the best harbor on the S. or W. shore of the lake. The climate is peculiarly bracing and healthful, and the atmosphere is remarkably clear and pure. It is estimated that the mortality is less than in any other city W. of Buffalo. The city is regularly laid out. The centre, near the Milwaukee and Menomonee rivers, is the business quarter; and the E. and W. parts, the former of which is built upon a high bluff overlooking the lake, while the latter is even still more elevated, are occupied by residences. The material used in building is principally a beautiful cream-colored brick, known as Milwaukee brick. The streets, except those in the commercial quarter, are generally well shaded. The city contains, beside a court house and county buildings, 88 churches (4 Baptist, 8 Congregational, 1 Dutch Reformed, 4 Episcopal, 6 Lutheran, 6 Methodist, 2 Presbyterian, 6 Roman Catholic, and 1

Unitarian), and 2 Jewish synagogues. Beside a large number of private and select schools, there are 9 public schools, one in each ward. The value of the school property amounts to about \$150,000. The schools are graded, and the higher as well as the elementary branches of education are taught in them. They are free to all, and supported partly by the state school fund and partly by a city tax. There are also a female college and a commercial college. The city has a chamber of commerce, 8 banks, 7 insurance companies, 2 orphan asylums, a Roman Catholic convent, and a hospital under the charge of the sisters of charity, 42 hotels, and a building erected by the United States in 1857-'8 for government purposes. The last is of Illinois marble, 8 stories high and with two fronts, one of 110 and the other of 60 feet. It is occupied by a post office, custom house, U. S. district court, collector's offices, library and grand jury rooms, U. S. marshal's office, U. S. district attorney's office, &c. There are 8 daily newspapers, 4 of which are printed in English and 4 in German. The following railroads centre at Milwaukee: the Milwaukee and Chicago, 85 m. long, and running along the lake shore; the Milwaukee and Minnesota, running from Milwaukee to La Crosse on the Mississippi, 200 m.; the Milwaukee and Horicon, which when completed will connect this city with Superior City, distant 325 m.; the Detroit and Milwaukee; the Milwaukee and Watertown; the Milwaukee and Beloit; and the Milwaukee and Mississippi, connecting Milwaukee with the Mississippi river at Prairie du Chien. The main feature in the commerce of Milwaukee is its vast and yearly increasing grain trade. The following table shows the yearly shipments of wheat and flour from Milwaukee:

Years.	Flour, bbls.	Wheat, bush.
1851.....	51,939	317,285
1852.....	92,995	564,404
1853.....	104,055	956,708
1854.....	145,083	1,809,453
1855.....	181,500	2,641,746
1856.....	188,415	2,761,979
1857.....	228,422	2,581,311
1858.....	228,638	2,994,313
1859.....	282,956	4,782,957

The city contains many of the best flouring mills in the West, and the reputation of several of its prominent brands of flour is excellent in the eastern and continental markets. The shipments of flour in 1859 were as follows: to Buffalo, 157,110 bbls.; to Ogdensburg, 83,892; to Canada, 54,535; to other ports, 7,775; by Detroit and Milwaukee railroad, 28,775; by Milwaukee and Chicago railroad, 869; total, 282,956. The wheat exported from Milwaukee in 1859 was destined to the following ports: to Buffalo, 2,650,517 bushels; to Oswego, 1,320,440; to Ogdensburg, 182,282; to Cleveland, 128,800; to Dunkirk, 20,800; to Canada, 341,707; to other ports, 63,748; by Detroit and Milwaukee railroad, 10,418; by Milwaukee and Chicago railroad, 20,800; total, 4,782,957. The following table gives the amount and value of flour

and grain exported from this port during the year 1859:

Flour.....	282,956 bbls., @ \$5 30 =	\$1,499,688 00
Wheat.....	4,782,957 bush., " 0 25 =	4,401,639 25
Oats.....	298,788 " " 0 20 1/2 =	117,599 25
Corn.....	46,072 " " 0 00 =	27,643 20
Barley.....	62,636 " " 0 00 =	37,581 00
Rye.....	10,267 " " 0 70 =	7,186 90
Total value.....		\$6,091,736 60

The provision trade of Milwaukee also promises to become second only to that in grain. The exports from this port of beef and pork in the years 1856 and 1859 were as follows, viz.: shipments of beef in 1856, 2,399 barrels—in 1859, 14,371; of pork in 1856, 11,742—in 1859, 81,661. The shipments of butter amounted in 1858 to 131,858 lbs., and in 1859 to 504,574 lbs. Five lines were engaged in 1859 in running steam freight vessels from Milwaukee to ports on the lower lakes. The number of arrivals and clearances at this port in 1858 were 2,113, and in 1859 4,638. The registered shipping in 1859 amounted to 82 vessels, including 7 steamers, with an aggregate burden of 17,753 tons. The total amount of grain and flour in store in the warehouses and elevators of the city, March 1, 1860, was 1,078,626 bushels.

MILYAS. See **LYCIA**.
MIMNERMUS, a Greek poet, born in Smyrna, flourished from about 634 to 600 B. C. He was a descendant of one of the colonists of that city from Colophon, whence he was generally called the Colophonian, and his remote ancestors came from the Elean Pylos. Of the fragments of his works which have come down to us, the most important is his celebrated poem of *Nanno*, the most ancient erotic elegy of Greek literature. They have been published separately by Bach (Leipsic, 1826). The best edition is by Schneidewin, in the *Delictus Protorum Elegiacorum Græcorum* (Göttingen, 1835).
MIMOSA. See **SENSITIVE PLANT**.

MINA BIRD (*gracula religiosa*, Linn.) a conirostral bird of the starling family and sub-family *graculina*. In this genus the bill is as long as the head, broad at the base and strong, with the culmen curved, sides compressed and nearly straight, and tip slightly notched; nostrils partially covered by the frontal plume; wings long, with the 1st quill rudimental, and the 2d shorter than the 3d and 4th, which are longest; tail short and nearly even; tarsi shorter than the middle toe, stout, and covered with strong scales; toes long, the outer the longest, and the hind one very long and strong; claws curved and robust; some parts of the head are naked or carunculated. This species, the best known of the genus, is about 10 1/2 inches long, of which the tail is 3, and the expanse of wings 19 inches; the body is round and plump; the color is velvet black, with green, blue, and purple reflections; on the wings is a white spectrum; the bill, feet, and caruncles behind the eyes, yellow. It is found in Java, Sumatra and other islands of the East Indian archipelago inhabiting the jungles, where it is seen in pairs or small parties in the tops of lofty trees, searching

for fruits, berries, and insects. It is easily domesticated, and becomes very familiar; it soon learns to whistle, sing, and talk, imitating the human voice, according to Latham, more nearly than any other bird; it is frequently kept as a cage bird in the East Indies, and sometimes in Europe and in this country, where as much as \$100 has not unfrequently been paid for a single bird. Another species, with similar habits, is the musical grackle (*G. musica*, Temm.), found also in the East Indies; and a few others are described, all from the Indian archipelago.

MINAS GERAES, the most elevated province of Brazil, lying between lat. $14^{\circ} 20'$ and $22^{\circ} 50'$ S. and long. $40^{\circ} 27'$ and 51° W., bounded N. by Bahia, E. by Bahia and Espiritu Santo, S. by Rio de Janeiro and São Paulo, and W. by Goyaz; area, 228,500 sq. m.; pop. in 1856, 1,300,000. It occupies a plateau which is traversed by detached mountain ranges, separated from each other by spacious pastoral valleys. The loftiest of its summits are Itacolumi (about 5,700 feet) and Itambi (about 6,000 feet). The principal rivers are the San Francisco, the Rio Grande do Sul, Rio Parnahiba, Rio Doce, and Jequitinhonha. The climate, owing to the great elevation of the province, is mild and healthful, save in the low alluvial districts adjoining the large rivers. The soil is in general very fertile, yielding in abundance and with little labor grain, fruits, cotton, tobacco, sugar, maize, manioc, coffee, indigo, ipecacuanha, jalap, liquorice, &c. The annual produce of Paraguay tea is about 20,000 lbs. of a superior quality. The forests are extensive and valuable; and the country abounds in horned cattle and swine. The great sources of wealth, however, are the minerals, among which are gold, silver, copper, platinum, iron, lead, mercury, antimony, bismuth, alum, sulphur, limestone, and millstone. Some of the most famous diamond districts are in this province. It possesses extensive iron works, the largest of which are near Ouro Preto, but no other manufactures of any importance. Minas Geraes sends 20 deputies and 10 senators to the imperial legislature, and has a provincial assembly of 36 members for the management of its own public affairs. It has made the greatest progress in education of any of the Brazilian provinces. Capital, Ouro Preto.

MINATITLAN, a small town on the W. bank of the river Coatzacoalcas, isthmus of Tehuantepec, Mexico, 20 m. from its mouth; pop. 460. It is the head of ship navigation on the Coatzacoalcas, and has obtained some notoriety and importance from being the Atlantic point of departure in the various attempts to establish an interoceanic communication by way of the isthmus of Tehuantepec. It is also the proposed terminus of the projected railway across that isthmus on the N. The country immediately around the town is low and subject to periodical inundations. Its trade is small and its industry limited. Cattle constitute the chief wealth of the people. A few cargoes of mahogany and other woods are shipped annually.

MINCIO (anc. *Mincius*), a river of N. Italy, which runs, under the name of Sarca, from the S. extremity of the Tyrol into the lake of Garda, at Riva, issues from it at Peschiera, when it takes the name of Mincio, and flowing southward, forms the boundary between the districts of Verona and Mantua; then, past Goita, turning S. E. it expands into a lake, near the E. end of which the fortress of Mantua stands; below which, contracting again, it discharges itself into the Po, near Governolo, after a course of over 40 m. It is navigable for barges throughout the greater part of its length.—The Mincio has been immortalized by Virgil, who dwelt on its banks. A battle was fought there in 197 B. C., in which the Insubres and Cenomani were defeated by the Romans. At a subsequent period the celebrated interview was held in a place on the Mincio between Pope Leo I. and Attila, which resulted in the withdrawal of the Hunnish forces from Italy. Bonaparte crossed the Mincio, May 27, 1796; and the Austrians under Bellegarde were defeated there by Brune, Dec. 25 and 26, 1800, and upward of 4,000 of them taken prisoners. Another victory over the Austrians was achieved there by the French under Eugène Beauharnais, Feb. 8, 1814, after a bloody conflict and severe losses on both sides. In 1859 the Mincio became again the theatre of war between the allied Sardinians and French and the Austrians, the latter endeavoring to concentrate their resistance on the line of the Mincio. After the battle of Solferino (June 24), the allied armies crossed the Mincio into Venetia, and the war was brought to a close by the peace of Villafranca (July 11), by which Lombardy was wrested from Austria, to be transferred to Sardinia, and the upper Mincio became a part of the boundary between the two states.

MIND, GOTTFRIED, a Swiss artist, better known under the name of Berner Friedli, born in Bern in 1768, died there, Nov. 7, 1814. A German landscape painter named Legel instructed him in his art, and the poor boy entered afterward the charity school of Pestalozzi, where he devoted himself exclusively to the study of design. Ignorant in all other branches of education, and ill-formed bodily, he shunned society and spent his life among cats, of which he executed such excellent pictures that he was called the Raphael of cats. He also excelled in pictures of bears, of children, and beggars. He died in the most abject poverty. Since his death his pictures have commanded extravagant prices.

MINDANAO. See PHILIPPINE ISLANDS.

MINDEN, a strongly fortified Prussian town (pop. about 12,000), capital of the administrative division of Minden (pop. 500,000), on the left bank of the Weser and on the declivity of a chain of mountains, 161 m. from Cologne and 229 m. by railway from Berlin. It has manufactories of woollens, linens, tobacco, soap, and sugar, and is the centre of the Cologne-Berlin railway, which, as well as the navigation of the Weser, produces much commercial activity. It

possesses an ancient Roman Catholic cathedral, and was once the capital of the see of Minden, which was founded by Charlemagne. It was also formerly the residence of some of the German emperors, and several diets were held there. Within 2 m. of Minden the railroad traverses the pass called Porta Westphalica. In a ruined chapel near it Wittekind was, according to tradition, baptized by Charlemagne. The French were defeated in the vicinity of Minden, Aug. 1, 1759, by an Anglo-Hanoverian army under Ferdinand of Brunswick.

MINDORO. See PHILIPPINE ISLANDS.

MINE (Fr. *mine*, a mine or ore), an excavation made in the earth for the extraction of ores, coal, salt or other minerals. If the object of the exploration is a rock of any kind, as limestone, marble, any sort of building stone, or slate, the excavation is known as a quarry. Mines of coal are treated in the article **COLLIERY**. Many metallic mines, with their treatment in ancient and modern times, are described in the articles on the several metals; and little need be added here of the accounts which have come down to us of the mines worked by the ancient Egyptians, Greeks, and Romans. Diodorus Siculus gives a more minute account of the mining processes of the Egyptians under the Ptolemies than we possess of any other ancient people. To the working of the gold mines upon the confines of Egypt criminals and prisoners of war were condemned, whole families together, and kept in continual servitude under cruel taskmasters and barbarian guards, that understood not the language of their prisoners. He describes their method of softening the gold-bearing rock by means of fires and of breaking it with iron picks, and their following the shining veins below the surface in dark winding passages, through which they were guided by lamps attached to their foreheads. Children, adults, and old people of both sexes were all condemned alike to the various operations of the mines; some extracting the ore, others removing it to those who crushed it into small pieces, and others grinding it in hand mills to powder. By others the earthy matters were washed away from the metallic particles upon broad tables a little inclined; and the smelters finally purified the ores by fire in earthen crucibles with suitable fluxes. From the earliest times the extraction of the mineral treasures stored in the rocks had been an object of great interest to man. Of some ancient races the chief records we possess are their mining explorations. In the article **COPPER** reference is made to the numerous mines of an unknown period recently discovered in the copper region of Lake Superior; and others of similar character have been met with in the copper and silver districts of New Mexico. While the implements employed by the workmen of these ancient mines were only rude hammers of stone, indicating but little progress in the mechanical arts, the immense amount of labor bestowed upon these and upon the work of ex-

tracting the metallic products showed the high value which an ignorant race set upon the metals. As mankind advanced in the arts and in civilization, new properties and uses of minerals were frequently discovered, till mining has grown to be one of the chief industrial pursuits of man. In tracing the veins of the ores he has been led successively on from the shallow pits of the ancients to greater and greater depths, overcoming with increasing mechanical skill and superior appliances the increasing difficulties of drainage, ventilation, and artificial illumination, till his works have been carried to depths exceeding 2,500 feet below the surface, and extending several miles in horizontal directions. As mines were worked in ancient times, and are yet among barbarous nations, the applications of labor-saving machinery are few and exceedingly rude. The rock through which the shafts are sunk and the horizontal galleries are driven is slowly broken off, sometimes by the aid of fires kept burning against it, and the fragments are laboriously brought to the surface upon the heads or shoulders of the workmen, who climb by insecure steps cut in the slopes, or by ladders formed of single logs with sticks for rounds inserted in their sides. Even the water which flows in is sometimes removed in the same way, or drawn out by hand. The simple windlass was a great invention for the miner, and is now universally in use for the sinking of shafts to moderate depths, and even for prosecuting mining operations to some extent. For heavier work the horse whim has been introduced in modern times; this is a drum attached to a vertical axle and carried around by one or several horses secured to its horizontal arms. Around the drum, which corresponds to the barrel of the windlass, the rope is wound, the ends of which pass over pulleys and down the shaft, supporting the buckets in which the water, ores, &c., are drawn up. Where water power was conveniently at hand, this has been used for the same purpose. With the invention of the steam engine more efficient machines of various kinds were brought into use; and when this was applied to mining purposes in 1765 by Watt in Cornwall, it was soon found that much more powerful hydraulic apparatus could be used than was ever before applied to mining, and large pumps with heavy cast iron pipes, capable of supporting a pressure of a column of water several hundred feet high, were substituted for the clumsy wooden pumps that had been previously in use. Thus the means were afforded of carrying the workings to greater depths than were ever before reached, and of raising to the surface the immense bodies of water that continually collect in deep excavations, as also of vastly larger quantities of ores and the materials removed in searching for them. The large transportation of the products of coal mines led to the invention of railways, which, constructed of wood, were laid from the mouths of the shafts at the collieries in the north of England down to the

places of shipment, and were in use for about 200 years before they were applied to other purposes. More recently introduced in the long levels of the mines, the tracks of wooden or iron rails have greatly added to the facilities of removing the excavated materials. While in this direction the mining art has been greatly advanced by modern improvements, the facilities of breaking rock from its solid bed have been but little increased since gunpowder was first applied to this purpose in the early part of the 17th century, as noticed in the article **BLASTING**. To the present day the method of penetrating the solid rock is exceedingly slow and laborious. Except where sufficiently soft to be worked out by the pick, it is drilled in holes of an inch to 2½ inches diameter, to the depth of 2 to 4 feet at a time, and the holes charged with powder are fired, breaking away as much rock as may be. In the long narrow passages of mines, often poorly ventilated, the smoke of the powder after blasting long keeps the men from their work, and envelopes them a great part of the time in an unhealthy atmosphere. The air is further vitiated by the numerous lamps and candles required for light, and also by the breathing of the men and the horses or mules which are employed in large mines. Its temperature also is raised by the same causes, as well as by the general increase of heat with increasing depth. Ventilation is therefore a matter of the first necessity, and is provided for in all mines by the arrangement of the shafts and levels, so as to secure a downward current of air through the lower openings, and an ascending current through the shafts, at the mouths of which chimneys are sometimes raised to increase the draft. In collieries, where noxious and explosive gases are generated, and thorough and rapid ventilation is all-important for the safety of the workmen, fires are kept burning at the bottom or top of the "upcast" shafts, by which a powerful draft is created and currents of air are drawn along through distant parts of the mine. Revolving fans and other machines are also employed to drive the air through the passages. (See **BLOWING MACHINES**.) —The mineral treasures of the earth are found not scattered indiscriminately in any country or in any rock formation, but mostly limited to certain groups of rock, and usually to certain districts, which acquire the name of mining districts. The discovery of a valuable mine in any long settled country out of one of these districts may always be regarded as extremely improbable. The ores occur in beds contained between the strata of rock, in veins which cross these, and in other forms (see **MINERAL VEINS**); and they are also met with in deposits among the gravel and sands of the beds of existing rivers and the more ancient diluvium, as gold and tin. Their presence is indicated by the finding of loose pieces upon the surface and of particles in the solid rocks, which may be sufficiently promising to lead to the exploration of the locality by blasting the rock in search of a con-

tinuous vein or bed; but as these are more commonly hidden beneath the soil, they are usually sought for by other means. The lead miner at the West is guided by depressed lines upon the surface, which indicate the existence of fissures in the limestone that contain the object of his search, and he sinks along these his "prospecting" shafts. In other districts the more usual practice is to dig long pits at right angles to the prevailing course of the veins of the district, carrying them down to the rock with the view of exposing one of the veins wherever this may be crossed. This method is called by the Cornish miners "coasteening." If the veins or beds lie at a gentle inclination, they may be cut by boring, a method better adapted for discovering coal beds than mineral veins. The surest mode of finding veins is by horizontal adits or cross cuts, at right angles with their course, driven into the sides of hills; this method is resorted to where the prospect of striking veins is very certain, and the hill rises high above the adit. The passage thus made continues to be used, while the mine is worked, as a road for bringing out the materials and as a drain for the waters. In mining districts that have been long worked explorations for new discoveries are mostly conducted underground in the old mines, as by driving cross cuts in search of new veins likely to be found parallel with the old, or by extending the works upon these from the places where they were abandoned as unprofitable. A vein being discovered upon the surface, the method of commencing mining operations varies according to its character and that of the ground. A shaft may be carried down upon it for the sake of proving its quality; but as veins are rarely vertical, and their dip or "underlay" is seldom at a uniform slope, a shaft of this character will not be convenient for permanent work; and therefore, as soon as the vein is found to be worthy of the expenditure, a vertical shaft is commenced at some distance in front of the outcrop, so as to strike the vein at a considerable depth. As soon as possible an adit should be commenced from the lowest point from which it can conveniently reach the vein at or near the shaft; and in some situations, as at the base of steep hills, this may be made the principal feature of the mine, until the vein being worked out above its level, the explorations are continued below. In some situations several adits may succeed each other at different levels down the slope of a long hill. The shaft is usually oblong (sometimes round), and may measure 6 feet by 4, 6 by 8, or 8 by 10 feet, or even larger, according to the purpose for which it is intended. The largest are partitioned off, so as to afford one compartment for the pumps, another for the hoisting, and it may be a third for the ladder ways. But as the shafts increase in number in the course of mining, separate ones often come to be appropriated to these special purposes. The sides of the shafts are protected from the falling in of loose materials by timbering, which in the case of quicksands and wet ground requires

to be constructed of great strength and closeness. As the shaft is carried vertically down it reaches nearer and nearer to the vein which dips toward it, and at any point a level may be driven across to meet the vein. This is usually done at the level of the adit, and at every 10 fathoms, or 60 feet, below; and after the shaft has reached the vein and been carried through it, the same system is continued, the direction of the cross cuts being reversed as the shaft has passed to the other side of the vein. The length of these cross cuts, it is apparent, now increases as the shaft gets further and further away from the plane of the vein. When the vein is struck by the shaft, the sinking is often carried down its slope, and the vertical shaft is at any time afterward continued. At the points where the vein is reached by the cross cuts and shaft, levels are driven along its course in each direction. They are parallel roads on the vein, succeeding each other at about every 60 feet in depth. To secure ventilation, small inclined shafts called winzes are sunk at any convenient distance, from 100 to 200 feet, along the levels, connecting each of these with the level above or below. By means of this work, which is all preparatory and not done for the sake of taking out ore, the vein is penetrated and explored in both directions along its course and also in depth. As it goes on, an idea is afforded of the productiveness of the mine, and the plan is varied according as the vein is found poor in certain places and rich in others. The expense of thus "opening a mine" before the work begins to be profitable is often very great, being rarely less than \$20,000, and sometimes reaching 10 or 20 times this amount. It is a venture of no little hazard, both from the uncertainty of the character of mineral veins and of the expenses which are to be incurred. The enterprises therefore are commonly conducted by companies, and the miners themselves often take a share of the risks. When in the opening of the mine sufficient room has been made for men to work to advantage in taking down the richer portions of the vein without interfering with others engaged in extending the levels and sinking the shafts and winzes, the "stoping" is commenced along the "backs" or portions of the vein extending up from the levels. This work is so named from its being carried on in successive steps or stopes, one set of men breaking down 6, 10, or 12 feet in height above the level, and going forward with this, while another follows, taking down the next 6, 10, or 12 feet above, and so on. The men are supported upon a platform resting on stulls, which are timbers whose ends are inserted in the opposite walls of the vein. The ore, as it is broken down, is allowed to fall to the floor of the level, whence it is run out in wagons or wheelbarrows to the shaft, and is then shovelled into the "kibbles" or iron buckets to be hoisted to the surface. The worthless stones which form a considerable part of the contents of veins are left as much as possible

upon the stulls. They serve to fill up the vacant space between the walls, and where the vein lies at a gentle slope they sustain the "hanging wall" from settling down upon the "foot wall." Unproductive parts of the vein are also left standing for the same purpose; and sometimes it is found necessary to build arch work in stone or brick masonry, and upon this the waste is piled instead of upon stulls. By this method, distinguished as "overhand stoping," a great advantage is gained in avoiding unnecessary raising and moving of the ore and rubbish, as in the other method, called "underhand stoping." By the latter the stopes are carried along the floor of the levels, one set of hands following another. This work may be sooner commenced in a mine, but it is objectionable, not only for the reason given, but also for the greater uncertainty of the character of the "ground" or vein, to be encountered, and the consequent inability to lay out beforehand the portions that may most advantageously be left standing and those which are most valuable to remove. In underhand stoping also the men are likely to be troubled by the flowing in of water upon their work. As the levels are carried far away from the shaft, the difficulties of getting the ore out and ventilating the mine render it necessary to sink again on the course of the vein on one or both sides of the original shaft; and the character of the vein being now understood, it may be found most judicious to sink the new shafts so as to cut the vein at a much greater depth than at first. To expedite this work, which in hard rock is exceedingly slow, sometimes not exceeding 2 or 3 feet in a week, though pushed day and night by as many men as can work in the limited space, surveys are made with extreme care through the intricate passages of the mine; and by the levels and cross cuts, some of which are extended for the purpose, the position of the proposed shaft is exactly defined at the different levels, and sets of men are placed to sink or to rise at each one of these. This work is well done, if when a deep shaft is thus completed daylight can be seen in looking up from the bottom. A shaft 1,224 feet deep was finished within one year in the consolidated mines of Cornwall by being worked on this plan from 15 different points. As mines continue to be worked, they are thus constantly extending in length and in depth also, until the increased cost of raising the water and ores equals the value of the products. Branch veins coming in at the sides often afford a new field for operations, and cross cuts are frequently driven off for the purpose of exploring the "country," as the miners call the solid rock outside the vein. Mines become poor and are abandoned, and other companies afterward return to them and make or sink fortunes anew; and thus in old mining districts, like Cornwall, they have been worked for hundreds of years. In that region the greatest depth attained is at the Tresavean copper mine near Redruth, which is 2,112 feet deep below the surface, or 1,230 be-

low the adit level, from which, on account of the varying level of the surface, the depth of mines is properly estimated. Its depth below the level of the sea is about 1,700 feet. On the continent of Europe some of the mines are still deeper. The deepest now worked in the world is a silver and lead mine at Andreasberg in the Hartz mountains, which has reached the depth of 2,500 feet. (See HARTZ.) At Kuttenberg in Bohemia is an abandoned mine in which the depth of 3,778 feet was reached. In the United States few if any mines yet exceed 800 feet in depth; this has been reached at the coal mines near Richmond, Va., and some of the anthracite mines of Pennsylvania and of the Lake Superior copper mines are fast approaching the same depth.—The keeping of deep mines free from water and raising their products to the surface requires steam engines of great power, and the cost of fuel becomes a heavy item in mining expenses. In Cornwall the plan has been adopted since 1812 of recording and publishing the amount of work done by the engines and the fuel consumed. The result is termed the “duty,” and is estimated by the number of pounds weight raised a foot high for one bushel of coal of 94 lbs. consumed. By reason of the attention thus directed to the subject, the working of the steam engines has been continually made more and more economical, while they have also been vastly increased in size, till some of the most powerful and efficient engines in the world are those of the Cornish mines. The largest are from 80 to 90 inch cylinders, and they are usually run but about 6 or 7 strokes a minute. In the last century the duty of the old atmospheric engine was rated at 5,500,000 lbs. raised a foot high for each bushel of coal. This was increased by Smeaton’s improvements to 9,500,000 lbs. Watt raised the duty by 1815 to 20,000,000, and this has since gradually increased till the average duty of the best Cornish engines exceeds 100,000,000 lbs., and has for a single engine reached 110,000,000. The great work of the engines is in pumping water up to the adits, through the largest of which great streams are continually flowing toward the sea. (See ADIT.) At a single mine called Huel Abraham 43,500 hogsheads of water have been raised every 24 hours from a depth of 1,441 feet. The working beam of the pumping engine is often seen projecting through the side of the engine house, and to it are suspended the pump rods, which pass directly down into the shaft. The pumps are arranged in sets of 100 to 200 feet lift each, the lower ones discharging into reservoirs excavated in the rock, from which the next set above receives its supply. The reservoirs are arranged to catch as much as possible of the water flowing down to their level, that it may not have to be raised from greater depths. In sinking a shaft the lowest pump is always a lifting pump, while the others are forcing pumps. The lifting pump is usually provided with one sliding length of pipe, so as to keep settling down as the rock is blasted away

in the bottom of the shaft, and new lengths of pipe are added as required. The pump rods of the forcing pumps are of very stiff wood about 4 inches square, the lengths strongly spliced and strapped together. To relieve the engine of their immense weight, which in very deep mines would be too great for the wood itself, they are counterpoised at intervals down the shafts by what are called “balance bobs,” being horizontal vibrating beams, placed in chambers hollowed out of the rock by the side of the shaft, one end of the beam attached to the pump rod and the other carrying a counterpoising weight of stone.—With the increasing depth of mines the labor of the workmen in going to and returning from their work becomes at last a serious consideration. It often requires an hour of toilsome effort to reach the surface from some of the deep Cornish mines. Ladders about 25 feet long and with as many steps are supported one below another, each upon a platform, called a “sollar,” through which a man-hole opens to the top of the next ladder below. A machine was contrived at the deep mines of the Hartz, and has since been introduced into Cornwall, France, Belgium, and Germany, by which the steam engine is made very ingeniously to carry the men either up or down by the vibration of the lever beam. One end of this is connected with two balance bobs, to which are hung two rods which pass down to the bottom of the shaft and move up and down with the vibration of the bobs, one rod ascending as the other descends. Upon each rod are fixed at distances 12 feet apart small platforms, large enough for a man to stand upon. At the end of each movement every platform on one rod stands on the same level with a corresponding platform on the other rod. A man standing on the one to go down is carried down the length of the stroke, say 6 feet, and finds himself opposite another platform on the other rod which had come up 6 feet as the other went down. He steps on to this, and with the next stroke goes down 6 feet again; and thus he continues to descend by stepping across from one rod to the other. In ascending he leaves each for the other at the end of its upward instead of its downward movement. One man can follow another, till there are as many men as steps on the rod. Men are also sometimes hoisted to the surface in the buckets, and in the deep coal mines in the iron cages in which the coal is brought up. This is a less expeditious way than by the “man machine,” described above, and is moreover attended with greater dangers.—Although machines of great power are applied to the working of mines, it is only by the patient toil of the miners that the rock is broken away from its bed and the excavations are slowly carried forward, the total length of which in the course of years is reckoned by miles. The tools they employ are the simple boring tools described under BLASTING, and the universal pick and shovel. With the former they penetrate the crevices of the rocks, remove loose pieces,

and drive with its hammer-shaped head the gads or little iron wedges into the cracks, thus taking away the rock in fragments; when too solid for this, they bore a hole with the drills in a position to break away the rock to the best advantage, one man holding the drill and the other striking with the mallet or steel hammer. This work the miner learns to do in any direction, and while placed in most cramped positions. The effect of the blast is to throw out fragments of the rock and to "shake" it, so that much more may be removed by the pick and gad. It is often the case that between the vein and the wall rock there is a crevice filled with clay, called by the miners "flucan." This is a great assistance in removing the vein, the stone readily breaking away from it; and it is also of advantage in defining the vein, so that when this becomes poor and undistinguishable from the wall rocks, the miners may not be led off and lose it. The materials of the vein are sometimes so soft, that they are removed by the pick without blasting, and the walls themselves are sometimes in a decomposed and rotten state. While this greatly reduces the cost of excavation, it involves an outlay for timbering which is always a considerable expense in mining. In such ground the levels require, as they are carried along, to be protected from caving in. For this purpose posts are set up at the sides, and each pair are connected across the top, and sometimes across the bottom also, by horizontal pieces let in to the posts. A lining of boards or poles behind and over the frame keeps the work secure. In very bad ground this lining is driven ahead close up to the work as this goes on. Shafts are secured in a somewhat similar manner. The timbering when closely made serves to check the flow of water into the mine; and when shafts are cribbed for this purpose, much skill is required to fit the work tightly, especially in the bottom to resist the pressure of the high column of water from the level above. The cribbing is in some instances constructed in mason work in brick or stone, and occasionally in iron.—The principal mines in the United States, and indeed on the American continent, as also in many other parts of the world, are worked to great extent by English miners, chiefly from Cornwall. They bring with them a skill derived from the experience of generations of miners, and habits that prevent their being readily drawn off to other pursuits, or even introducing any changes in their methods of work, which the different conditions of the mines and country require. Improvements in these are commonly made by our own people, who, however, except in California, never are known as a class of miners like the Cornish, Irish, Welsh, and Germans. The system of labor established at the large mines is like that in Cornwall; and by this it is made the interest of the men to accomplish the greatest practicable amount of work. The sinking of shafts, driving of levels, and all underground operations which are not directed to the imme-

diately extraction of ore, are classed as "dead work" or "tut work," and the miners engaged in them are called tut workmen. They usually work by contract, taking a job to sink a shaft of given dimensions so many feet or fathoms in depth, or to drive a level so many feet or fathoms, delivering at the surface the stuff they remove. The common practice is for each party or gang of men to divide into 8 shifts, one succeeding another every 8 hours. By this plan the work is kept constantly going on, which is not the case when it is conducted by two 10 hour shifts. The men have the use of the general mining machinery for hoisting and pumping, but pay for their own powder, fuse, steel, sharpening of tools, &c.—The breaking down and extraction of the ore is the productive labor of the mine, in contradistinction to the dead work, and is to a great extent conducted by miners called "tributers," who work on tribute, that is, for a certain share of the products they can extract within a given time in the portion of the mine assigned to them. At large mines contracts of this kind are let out at regular times, called "setting days," which may be once every two months, the men collecting round the counting houses and bidding for the several jobs or "pitches," as these are put up at auction by the mining captains. By the tribute system it is made the interest of the miner to extract the greatest amount of ore at the least cost, to guard against all waste as the ore passes through the different processes of preparation for sale, and to search carefully that no rich bunches of ore escape notice and are left behind in the mine. He takes a portion of the risk of mining, being benefited if the pitch turns out better than expected, and suffering loss if the lode grows poor. The work upon the surface is generally paid for by the day, and the same is the case with some of the underground work.—It has long been the practice of different governments to reserve the mineral treasures of the lands in conveying to individuals the proprietorship of the surface; and whenever these treasures are brought to light they are either farmed out to individuals or companies, conceded as marks of special favor, or worked under the immediate direction of the government. The policy pursued by the Russian government of taking possession of all important mineral discoveries must tend to check the development of the mineral resources of the country, and lead to the concealment of valuable discoveries. Not only has this system operated thus injuriously, but the mines, rich as they are, have proved of little value to the state in consequence of the irregular practices and abuses attendant upon their exploration by government agents. The emperor therefore is about to abandon the system, and transfer the mines to companies, together with special facilities to aid in their continued development. The old Spanish mining laws, which were established in all the Spanish American possessions, encouraged discovery and the steady working of mines by

allowing any individual, Spaniard or foreigner, to take up a tract of sufficient extent for a mine, and to hold the same so long as he continued to work it, and pay the moderate government dues. The owner of the soil was entitled to damages assessed by disinterested parties for the use of the surface required for mining purposes. These are the existing laws in Cuba, and with some modifications in Mexico and the mining countries of South America which formerly belonged to Spain. They apply to all discoveries of precious stones, and metallic, combustible, and saline substances, whether found upon or below the surface. Mines of mercury are excepted, these being especially reserved to the crown. By notifying the proper officer of the district, the applicant obtains possession of a rectangular plot or *pertenencia*, measuring 200 *varas* (182.6 English yards) in length on the vein by 100 *varas* in width, which, in case of the discovery being new, or in case of reopening abandoned mines, may be extended to 600 *varas* on the vein by the original width. Companies under some circumstances may secure 4 *pertenencias*. For each one an annual tax was laid of 1,000 *reales de vellon* and 5 per cent. of the mineral product. Proprietors can dispose of their interest as of any other property, but their rights are lost, and the mines become subject to denouncement again by other parties, in case of non-fulfilment of the requirements of the law, such as sinking a shaft within 90 days, working the mine with at least 4 men to each *pertenencia*, not abandoning it for 4 months at a time, and not allowing the buildings to go to ruin.—Though mining is a special department of the Spanish government, little publicity is given to the statistics of the mineral productions. But in most of the other countries of Europe, as England, France, Sweden, Norway, Prussia, Austria, and Saxony, full records are kept and published, which present a fair approximation to the real production of these countries.—In France the *département des mines* is an important branch of the government, including matters relating not only to mines themselves, but also to turf and peat, metallurgical works, dangerous and unwholesome establishments, steam engines, mineral springs, geology, agriculture, workmen, mining schools, &c. The corps of *ingénieurs des mines* has included more distinguished scientific men than any other learned body in the world. From a very early period great attention has been given in that country to mining legislation; and within a few years one of the *ingénieurs des mines*, M. Lamé Fleury, has been commissioned to collect together all the various laws, decrees, and public acts of the government in this department. This he has done, commencing with the time of Charles VI. The king appears to have had the sole disposition of mining property, granting concessions to whomsoever he pleased, though there have also been grand masters, the last of whom was the duke de Bourbon, who performed the same office. Coal mines were free from this control

until the abuses and accidents incident to working them rendered royal interference necessary. The last recorded concession was of tin, lead, and coal mines at Cotentin in 1791. In that year it was proposed to give up the control of mining property to the proprietor of the soil, against which Mirabeau pleaded strongly; and a law was passed compromising the matter, the proprietor of the soil retaining all to the depth of 100 feet, below which the government took possession. This proved unsatisfactory, and the law was modified in 1810, an improved code being soon after established, by which the government reserved the right of granting concessions, and compensation was provided to the land owner for damages to which he might be subjected. It is believed that the intention was that this law should lead to the land owner acquiring full possession on his giving satisfactory security for his ability to develop the mineral treasures of his lands; but subsequent legislation has confirmed the government in their control. The law of 1838 gave to the state the right of withdrawing a concession under certain circumstances, and that of 1852 rendered necessary the assent of the state for the union of different concessions. A principal cause of the interference of the governments in mining matters has been the terrible explosions in collieries involving the loss of many lives. In England it is only in reference to this object that the government exercises any special jurisdiction over mines. Collieries are there subject to the inspection of engineers appointed for the purpose of insuring, by ventilation and a proper system of operations, protection against accidents. Under the laws of Great Britain mines have generally been the property of the lords of the soil, those containing gold and silver excepted, which up to the reign of William and Mary were termed royal mines, and paid dues to the crown. The government also held mining properties in the forest of Dean, which were leased somewhat on the plan of the concessions of other countries. In Scotland, previous to 1775, persons employed about the coal mines were held as property, and were transferable with the estate. They were emancipated by the act 15 George III., c. 28. Companies engaging in mining enterprises at present in Great Britain obtain from the lord of the land a lease called a "set," and he is usually paid by a royalty or rent in money or a percentage of the products. The average of the lord's dues is usually about $\frac{1}{3}$ of the gross products. In the United States deeds of real estate convey the entire control of all minerals belonging to the property, unless these are specially reserved. The law recognizes no distinction between mining and other property.—In several of the mining districts and capitals of Europe, schools are established particularly for instruction in those branches connected with mining; and some of these enjoy a high reputation, as that of Freiberg in Saxony, that of Olansthal in the Hartz, and the *école des mines* of Paris. The school at Schemnitz in

Hungary has been founded since 1760. In England a government school of mines was opened in London in Nov. 1851, in connection with the "museum of practical geology;" in Truro, Cornwall, and in Bristol, schools of similar character are established. In the United States no institution exists specially devoted to these objects.—The statistics of the metallic produce of the principal mining countries of the world for the year 1854 are presented by Mr. J. D. Whitney in his work entitled "The Metallic Wealth of the United States," and his tables, from which the accompanying table is prepared, offer the nearest approximation for estimating the value of these products, and the relative importance of different countries in this department. In the production of some of the metals, for the United States especially, more facts of recent date may be found by reference to the separate articles in this work. A discrepancy may sometimes be observed in statistics of this character, from want of distinction between the crude products of the mines and the metals into which they are afterward converted; and where gold is the principal mineral product, which is obtained originally in the metallic state, this confusion is perhaps more liable to occur, the other metallic products being estimated in their crude condition of ores. The English government returns, as annually compiled by Mr. Robert Hunt, keeper of mining records, specify in separate tables the amount and value of the crude products and of the metals derived from them. The following later memoranda may be added to the information contained in the above table. The Russian product of gold, silver, platinum, iron, copper, lead, zinc, coal, and salt, is estimated by M. L. de Tegoborski ("Commentaries on the Productive Forces of Russia," London, 1855) to reach the value of £5,460,000, of which more than 55 per cent. is gold alone. Adding to these the value of the granite, ornamental stones, gems, &c., of Siberia, the gross value of the mineral products of the empire is rated at £6,838,833. The metallic products of the Austrian mines in 1851 were reckoned at 26,469,839 florins (\$12,970,221), and the salt product at 58,194,942 florins (\$26,065,521). The mineral product of Prussia is found from year to year to amount in value to about £5,000,000. In 1857 it was made up as follows: coal, £3,522,802; lignite, £898,380; iron ore, £357,605; zinc ore, £457,808; lead ore, £257,662; copper ore, £98,614; other minerals, £27,000; total, £5,111,821. Prussia produces more zinc than all the other countries of the world. In France the annual value of the mineral products is rated by M. Schnitzler at £16,800,000, including the products of the quarries and of the peat bogs to the amount of £1,600,000. His rates of valuation are much higher than those of Te-

Italy	882,500	0.010	0.0090
Switzerland	375,000	0.005	0.0004

MINER, THOMAS, an American physician, born in Middletown, Conn., Oct. 15, 1777, died in Worcester, Mass., April 23, 1841. He was graduated at Yale college in 1796. The next 6 years were passed in teaching, and in the study of law, which in 1808 he abandoned for medicine, and in 1807 he commenced practice at Middletown. There prevailed about 1809 in the Connecticut valley a malignant epidemic fever, for which Dr. Miner and his friend Dr. William Tully pursued a new mode of treatment, the former making careful notes of his cases, and numerous autopsies of those which proved fatal. In 1819 he was compelled by disease of the heart to withdraw from active life, and confined himself to a consulting practice and writing. In 1823 he published, in connection with Dr. Tully, "Essays on Fevers and other Subjects," and in 1825 a treatise on "Typhus Syncopalis." Both works were severely criticized, but enjoyed a wide circulation, and led to the formation of a school in medicine which still has numerous adherents.

MINERAL POINT, the capital of Iowa co., Wisconsin, on a branch of the Pickatonokee river, 47 m. W. S. W. from Madison; pop. in 1855, 8,462. It is in the midst of a rich mineral district, yielding large quantities of lead and copper. It has an active business, and contained in 1850 a number of stores, a bank, 4 smelting furnaces, and 5 churches. It is connected by a railroad to Warren with the Illinois central and Galena and Chicago union railroads.

MINERAL VEIN, as commonly understood, a collection of mineral matters, which have been slowly brought together and consolidated in elongated cracks or fissures in the rocks. Dikes are collections formed of molten rock, as lava, which has suddenly flowed into fissures and cooled. Among the earthy minerals, which form the gangue or vein stones, are often found metallic ores, and it is from this source that the chief supplies of the useful metals are obtained. Veins worked for these are called by the miners "lodes." A distinction is made by geologists between veins and beds, which in mining is not often recognized. By the latter term are understood bodies of mineral substances, metalliferous or not, which were deposited at the same time with the rocks which include them; and as in the recent progress of theoretical geology some rock formations that were regarded as of intrusive igneous origin are now considered as derived from sedimentary deposition, so it has happened that many repositories of metallic ores heretofore considered veins are now classed as beds. This is especially the case with the collections of magnetic and specular iron ores like those of New York and New Jersey, the origin of which is now regarded by many as synchronous with the rocks which contain them. In cases like this the distinction is rather of theoretical than of practical importance, the bodies of ore having as great permanency for practical purposes as veins. What some writers call "segregated" veins (collections of mineral matters spread in irregular sheets through rocks, and presenting no evidence of being formed in preëxisting fissures) may for the most part be considered as metamorphosed beds.—Veins are met with in almost all rocks, are traced for miles in length, and penetrate the crust of the earth deeper than man has ever been able to follow them. The origin of the fissures is more readily understood than the source of the materials that fill them. The forces which produce cracks in clays by their shrinkage, and in other substances by change of temperature, also operate to rend apart the solid strata, and fissures in these are also produced by earthquakes and volcanic action. Such openings are naturally found very irregular in their dimensions, and, in districts where earthquake movements have been frequent, interrupted in their continuity, crossed by other fissures of later formation, and ramifying into side openings, some of which may prove as extensive as that which appeared to be the main fissure.

Such is the character of mineral veins where they form an important feature of the geological structure of the country. They are met with in rocks of all ages and in various stages of completion. The fissure is sometimes seen still open, containing only loose earth and stones that have fallen in from above, as in that which crosses the Shawangunk mountain in Ulster co., N. Y., referred to in the article LEAD; and sometimes it is partially filled with vein stones or ore, open spaces still remaining unfilled, and forming caverns on the line of the vein, instances of which are noticed in the same article. The fissure again may be quite filled with mineral substances, which may be closely attached to the walls, as if all were originally formed at the same time; or, as is more commonly the case, a parting seam may be found on one or both sides, separating the vein stone from the wall rock, and the faces of each are then often seen presenting a smooth surface, as if they had been rubbed together. A thin layer of tough clay, called by the miners "flucan," is commonly interposed in the seam between the vein and its walls. Veins usually occur in groups of several together, lying nearly parallel to each other both in direction and inclination downward; but as they are followed in one or the other direction along the surface or on their slope down, which is called their dip or "underlay," they are often found to run into each other. While their general line is straight, it is more or less waving in places; and their dip is more variable, often becoming steeper at greater depths, and changing to greater or less steepness along their course. The position of veins in regard to the rocks which contain them is sometimes across their strata and sometimes with them; and in the latter case the veins are often found both in dip and direction to pass across one stratum and continue between different layers from those in which they were first seen, thus establishing their character as veins formed in fissures in contradistinction to beds. Veins of this nature are seen in the gold region of the southern states, and generally along the Appalachian belt also in the western portion of the Lake Superior copper region. Veins cutting across the strata are found throughout the Keweenaw Point district of the same region. Along the line of contact of two rocks of different character, as granite, gneiss, or trap with sandstone or limestone, veins frequently occur, and branches lead off into the rock on one side or the other. Many of the copper lodes of Connecticut and New Jersey, and the lead mines of the Schuylkill, are thus found at the contact of the granitic or trappean rocks with the red sandstone. It appears as if fissures may have opened originally in such positions, and also between adjoining strata of the same rock, for the reason that the disrupting force, when not directed at right angles across the strata, found along these lines the least resistance. A vein which cuts through rocks of different kinds changes not merely as regards its contents, but also in respect to its dimensions,

with the rocks which include it; and it is almost universally the case, that a vein which is productive in one rock ceases to be so as it is followed from this into another. In the western lead region fissures producing lead in the limestone are unproductive, if not entirely lost in the underlying sandstones.—The veins of a mining district exhibit features that distinguish them from those of other districts. In Cornwall they are found of several sets or systems, which are classed according to the periods of their formation, those which are continuous through others being recognized as belonging to a later period than the veins which are cut. The veins of this district thus distinguished have been referred to as many as 8 systems. The most important of these are the E. and W. copper lodes, which cut and displace more or less the older formed veins, in which tin is the predominant ore. Another set of copper lodes lies in a N. E. and S. W. direction; and "cross courses," which are mineral veins containing very little ore (and this in Cornwall only lead) extend in a N. and S. direction. In the Freiberg (Saxony) district the same number of systems were recognized by Werner as are found in Cornwall. The oldest and most important veins which have produced the chief supplies of iron and silver, run N. and S. They are crossed by others which lie N. E. and S. W., these by the N. and S. veins, and these again by E. and W. cross courses, and so on. In this small district of only 10 or 11 miles in length by 4 or 5 in breadth, more than 900 different veins have been recognized. These by late observers have been classed in 4 sets, which are distinguished by the contents of the veins as well as by their direction. An account of these lodes is given by Weissenbach in a paper published in 1844, "Contributions to the Knowledge of Mineral Veins;" and the classification of veins propounded by the author is presented by Mr. J. D. Whitney in his work, "The Metallic Wealth of the United States," p. 44. The mineral veins of the United States, though found pursuing different directions in the same district, rarely cross and displace each other as in Europe, and the irregularities arising from heaves and faults which there occasion so great perplexity and trouble in following the lodes, are here comparatively unknown. The veins of bedded magnetic iron ore of New Jersey and of northern New York are frequently covered over by the surface, and cut off at different depths by layers called "caps" of the gneiss rocks in which they are contained. Through the cap no fissure nor even crack is found leading from the body of ore above to its extension below. They are of several feet in thickness, and when penetrated the ore is often recovered on its surface line. A similar feature is met with at the Chañarcillo silver mines of Chili, the veins which are cut off by a stratum of tough, hornstone called a *masa* (tablet), sinking through this, in one instance 260 ft. the vein was again found beneath the stratum.

many as 7 such belts have been found intersecting a vein, and in the spaces between them the vein was continuous, and particularly rich in the *masses*.—The width of veins is very variable, as would naturally result from the nature of the original fissures; and that of any single vein is subject to great irregularities, especially where its walls have been moved subsequent to their separating, so as no longer to present corresponding depressions and prominences opposite each other. In places the fissures will thus be found nearly closed by the contact of the two walls, and in others opening it into wide spaces by their separation. At the copper mines in E. Tennessee the lodes attain a thickness of more than 50 feet; but a more common width of veins is below 6 feet. In Cornwall the mean width of the lodes at less than 100 fathoms in depth is rated at 3.97 feet, and at greater depths only 3.36 feet. A vein is described in Chili as about 9 feet thick, which has been traced for 90 miles, and is accompanied by branches that extend 30 miles. The *vein madre* of Guanajuato, Mexico, the most extensively worked and probably the richest vein in the world, has been opened in places along the line of the strata for about 12 miles; it sometimes attains a width of nearly 200 feet. The *vein grande* of Zacatecas averages 25 or 30 feet, and its maximum width is about 75 feet. Veins, however, are not rich in proportion to their size; and in Mexico it is found that some of the most profitable to work are small, it may be not exceeding a few inches in width.—The contents of veins are rarely altogether of a metallic character. A variety of minerals, called vein stones or the gangue, make up the chief part of metallic veins, among which quartz is the most common, and next to this calcareous spar. Sulphate of barytes, fluor spar, and spathic iron ore are also common vein stones. They occur together with other minerals intermingled with the mass, and near the surface especially often constitute the whole body of the lode, the ores being entirely wanting, or seen only in small particles or in scattered bunches. Usually no order is perceived in the arrangement of the gangue and ores, but in some veins there is a marked exception to this, the materials being symmetrically arranged in corresponding layers on each side proceeding from the wall to the centre. The layers of corresponding pairs sometimes agree in thickness as exactly as they could be set off with a pair of dividers. A vein near Freiberg described by Weissenbach has adhering to each wall a thin layer of blende, inside of this quartz, then fluor spar, then another thin layer of blende, then sulphate of barytes, through the middle of which in each layer is traced a thin streak of iron pyrites; another such streak separates the barytes from the fluor spar, which is the next inner layer, and iron pyrites again lies along the inner side of the fluor spar, separating it from the great central body of the vein, which is composed of calcareous spar, down the middle portion of which a

cavity is traced, showing that the operation of filling the vein had not been quite completed. On the N. shore of Lake Superior, opposite Isle Royale, a vein measured by the writer in 1846 presented the following symmetrical layers: on each side, next the walls of trap, calcareous spar, 8 inches thick; then trap, each layer 6 inches thick; then quartz, each layer $\frac{1}{2}$ inch thick; and within these calcareous spar 20 inches thick, forming the central mass of the vein. Quartz in such veins forms crystals, which project toward the centre at right angles with the walls. In the centre the crystals from each side interlock at their points and form what are called combs. Other parallel lines of these are also met with in some veins nearer the sides, and it is supposed that each one of them was once the central line of the fissure, which was further opened after their deposition, thus giving place to a new central line. Beside these deposits which have been regularly laid upon the walls of fissures, it may be by precipitation from saline solutions, or by sublimations, other materials are found in veins which appear to have fallen in either from above or from the walls, such as pebbles, fragments of rock, and clay. The last named is gathered in the cavities, and often forms a lining between the vein and its walls. Masses of the wall rock are sometimes met with so large, that the dividing of the vein around them appears like the leading off of a branch; nor is this found not to be the case, until the divided portions meet again on the other side of the interposed mass. The miners call such a mass a "horse," probably from the vein going down each side of it like a saddle on the back of a horse. The ores occur in bunches, strings, and layers very irregularly distributed, and usually of many varieties associated together. The ores of one metal commonly prevail either throughout the mine or to a certain depth, below which others may be found more productive. They often lie in courses or parallel belts, which slope in one or the other direction on the line of the vein, and between such courses the workings are comparatively unproductive. Their position and slope being once determined, the works for reaching them most economically on their extension may be planned in advance with confidence. Large developments of ores are looked for where branches drop into the main vein. Near the surface veins are not often found so rich as at some depth below, at least beyond the reach of atmospheric influences; but when once in what the miners call "settled ground," no improvement need be expected as the result merely of greater depth. Many rich lodes of the sulphurets of copper show near the surface no appearance of this metal; the ores have been changed into soluble compounds and the sulphur and copper carried off, leaving behind the ferruginous oxides, one of the products of the chemical changes, in the form of ochreous masses, known by the miners as "gossan," or sometimes, as at the great lodes of E. Tennessee, in solid rocks

of hematite. The condition of vein stones and ores is sometimes very favorable for the continual progress of chemical changes. When sufficiently open for the percolation of water among them, this becomes charged with various salts, and in different proportions at different depths. Electrical currents are induced by the reaction of these solutions upon each other and the various substances they come in contact with, and new mineral compounds are generated and deposited. Numerous instances are recorded of changes thus going on in mineral veins, and the formation of fresh deposits of ore. Portions of a vein have been worked a second time, and the fact been unsuspected until the tools of the ancient miners were discovered in the solid vein stone. Breithaupt records an instance of a miner having fallen down a deep part of the mine at Fahlun, Sweden, and his body, not recovered until the lapse of 60 years, being then found converted into iron pyrites, which had slowly replaced the organic materials, retaining their forms. Being taken out and exposed to the atmosphere, the pyrites after a time decomposed and crumbled away. Upon the walls of the McCulloch mine in Guilford co., N. C., the writer has gathered crystals of sulphate of copper, a recent formation from the decomposition of the pyritous copper of the mine. Such facts suggest the most plausible mode by which the materials of many of the mineral veins have been distributed, but they afford no clew to the original source of the ingredients introduced. Water highly heated and under intense pressure, such as that derived from the great depths to which it penetrates, acquires an extraordinary solvent power, as is witnessed in the deposits of thermal springs, and in the marble-like incrustations that gather upon the inner surface of steam boilers. M. de Senarmont, making use of such solutions as are found in thermal springs, as of carbonic and hydrosulphuric gases, the alkaline sulphates and bicarbonates, heated from 100° to 350° C. in glass tubes hermetically sealed, succeeded in obtaining from different compounds others precisely like the natural ores and various minerals found in veins, some of them crystallized, and different from any products ever before obtained by the humid process. He thus imitated the natural product of copper and silver, as these metals are found attached together, but not in combination, at the Lake Superior mines. Red oxide of iron and red oxide of copper, like the native ores, were thus produced; carbonates and sulphurets of various metals, sulphate of barytes, and quartz in crystals of the most common form. Such solutions, coming in contact with different strata, may possibly be so influenced by the electro-chemical action thus generated as to part with portions of their metallic ingredients; or, penetrating these rocks, may gather the metallic particles disseminated through them, and slowly deposit these particles upon the walls of the fissure. It is only by reference to such principles that attempts

are made to account for the changes observed in a vein accompanying the change of rock in which it is found. The incrustation of mineral substances in the fissures and upon the walls of volcanic craters, and of the oxide of zinc upon the inner walls of blast furnaces in forms exactly resembling in their parallel layers natural ores from veins (see CADMIA), suggests the mode of deposition by sublimation as having taken place in some veins. There is no doubt that the great bodies of the ores of mercury found in some countries have been thus collected. By such agencies the walls themselves of the fissures may be penetrated by the metallic vapors, and becoming charged with these give rise on their condensation to the metalliferous strata often found in contact with veins. The sublimation theory was enunciated by the German miner Lehmann in 1753, and is considered as offering a not improbable explanation of the abundant occurrence of sulphurets in veins, and produced by the action of hydrosulphuretted acid vapors upon other metallic compounds. Beside these modes which have probably operated to produce mineral veins, other theories also have been proposed by different chemists and geologists; as that their materials had been introduced from below in a molten condition, and became solidified in cooling like lava in a dike; but many of the features of veins which have been already considered are entirely opposed to this theory. Werner supposed the materials might have been deposited from solutions introduced from above. Ocherous springs, gathering up from the rocks around their ferruginous ingredients, might thus carry oxide of iron into clefts, but the deposit left upon the surface would betray the origin of this. About metallic veins no superficial deposits are found that would support this theory, while the manner in which the mineral substances are distributed in lodes is entirely opposed to it.—Among the important works which treat upon mineral veins may be named the "Report on the Geology of Cornwall, Devon, and West Somerset," by Henry T. De la Beche (London, 1839); *De la richesse minérale*, by A. M. H. de Villefosse (Paris, 1819); *Lehrbuch der chemischen und physicalischen Geologie*, by Gustav Bischof (Bonn, 1854); and various papers in the "Proceedings of the Geological Society of Cornwall," by Messrs. Robert W. Fox, Joseph Carne, John Hawkins, and others.

MINERAL WATERS, those which, either from the matters dissolved in them, or from their temperature, possess medicinal properties. All spring and well waters are impregnated more or less with mineral elements, derived from the soil through which they pass; but only such as may be used for the treatment of disease, or for some special influence on the animal economy, are classed as mineral waters. It is not necessary that the amount of mineral matter in them should be large, for in some of the most highly prized it is very small, and others, by common consent classed as mineral

waters, seem to owe their curative power to increased temperature alone. Mineral waters are commonly first recognized by some peculiarity in taste or smell, or by a higher temperature; but their value has been generally established by the cures they may have effected. As the methods of analytical chemistry have been improved, they have been used to analyze the most celebrated mineral waters. The problem is always a difficult one, and very much yet remains to be done. Of the hundreds of mineral springs in America very few have been thoroughly analyzed. Mineral waters are used both for drinking and for bathing, the chief use of the thermal or warm springs being for the bath. The Greeks and Romans were well acquainted with hot and warm springs; they also used mineral waters for drinking. The luxurious Romans were accustomed to spend their summer months at Baisæ, where the sulphur waters were used as the sulphur springs of Virginia, Harrowgate in England, and Aix la Chapelle are at this day. The salts most commonly found in mineral waters are the chlorides of sodium, calcium, and magnesium; the sulphates of potash, soda, lime, magnesia, and alumina; the carbonates of potash and soda, and bicarbonates of lime, magnesia, and iron, with several nitrates, silicates, and the sulphides, iodides, and bromides of the alkalies and alkaline earths, many of these compounds being kept in solution by the carbonic acid gas or by sulphuretted hydrogen, with which some of the most noted mineral waters are charged. It is claimed that recent analysis has shown the famous Carlsbad water to contain carbonic acid, the salts of manganese, iron, iodine, bromine, arsenic, copper, lead, tin, antimony, and some others.—Mineral waters are generally divided into 4 classes: acidulous, sulphureous, chalybeate, and saline. Acidulous or carbonated waters are those charged with carbonic acid; to this class belong the Sweet springs of Virginia, and the Seltzer, Spa, and Pyrmont in Europe. Sulphur waters are those impregnated with sulphuretted hydrogen or soluble sulphides, such as the White, Red, and Salt Sulphur of Virginia, Harrowgate in England, and Aix la Chapelle in Rhenish Prussia. Chalybeate or ferruginous waters are those which contain in solution the salts of iron; among this class are the Bedford, Pittsburgh, and yellow springs in the United States, Tunbridge and Brighton in England, and Wiesbaden in Germany. The 4th class, saline springs, embraces waters of the greatest diversity, such as the Saratoga in the United States, Obeltenham and Bath in England, and Seidlitz in Bohemia.—The value of mineral waters has been best shown in the treatment of obscure and chronic diseases. In many instances persons have been restored to health, or greatly relieved, by use of mineral waters when all other remedies proved of no avail. This has sometimes happened for the reason that such waters often contain compounds not yet known to chemistry or pharmacy; the salts of iodine and bromine are of recent

discovery in chemistry, but as component parts of certain mineral waters have been successfully used for centuries in the treatment of disease. So there may be other remedies still unrecognized except in the effects produced by particular waters. The best known mineral waters are now prescribed by the faculty in certain diseases with as much confidence as any preparation known to the apothecary. They are often recommended in the treatment of diseases of the skin, liver, spleen, and urinary organs; in dyspepsia, jaundice, gout, and rheumatism. The chalybeate waters are said to strengthen the tone of the stomach and to increase the red particles in the blood, which, according to Liebig, perform an important part in respiration. Experiments have proved that the number of red particles in the blood may be doubled by the use of preparations of iron.—The number of mineral springs in the United States is very great, but many of them are little known beyond their own neighborhoods. Bell, in his work on the "Mineral and Thermal Springs of the United States and Canada," has given a brief description of nearly all of note. Dr. Moorman has recently presented the claims especially of Virginia in "The Virginia Springs and Springs of the South and West." The English mineral springs have been described popularly and scientifically by Dr. A. B. Granville, "Spas of England" (1842). For an account of the springs of Germany, some of which are very justly celebrated, the work of Blum, *Natürliche und künstliche Mineralwasser* (Brunswick, 1858), may be consulted. The mineral springs of France have been carefully studied both by chemists and physicians, and the results given by a number of recent writers, among whom may be mentioned Durand-Fardel, *Traité thérapeutique des eaux minérales de France et de l'étranger, et de leur emploi dans les maladies chroniques* (8vo., Paris, 1857), in which are described and classified nearly 250 springs in France; the same author, assisted by others, *Dictionnaire des eaux minérales et d'hydrologie médicale* (Paris, 1859-'60); Ossian Henry on the analysis of mineral waters (8vo., Paris, 1858); and Lefort's *Traité de chimie hydrologique* (8vo., Paris, 1859).—Many of the most celebrated mineral waters having been analyzed, different chemists, both in the United States and Europe, have attempted to prepare artificial substitutes which shall exactly imitate the natural. Others have endeavored to compound and invent artificial waters which shall possess specific properties and be applicable in particular diseases. A small volume by Dr. H. Hager (in German) on the manufacture of artificial mineral waters describes the apparatus used for the purpose in Germany, where considerable success has been attained.

MINERALOGY, the science which treats of natural inorganic bodies belonging to or found upon the earth, distinguishes the several varieties from each other by their peculiar physical or chemical properties, and groups them into

systems. In its domain are included all natural products which belong neither to animal nor vegetable bodies, but not artificial compounds, such as are in vast numbers produced only by the hands of man. Often, however, it happens that compounds known only as artificial come to be discovered as natural products also, and are thereafter classed as minerals. From the various forms which the same element or compound assumes under different conditions, being sometimes a solid, a fluid, or a gas, it is obvious that no distinction can be made on these grounds among inorganic bodies; and hence water, the air, and other natural gases, are as necessarily included among minerals as the solid bodies of which they may form a part.—As a science mineralogy is of modern date. For the sake of their useful qualities and beautiful appearance stones of various kinds have always been an object of interest to man. But the ancients, knowing nothing of their chemical composition and but little of their properties, were incompetent to establish any science of mineralogy. Their authors frequently alluded to minerals, and sometimes attempted descriptions of them; but these were so vague, that even in the treatise of Theophrastus upon stones, and in those of Pliny in the last 5 books of his great work on natural history, which were specially devoted to this subject, a great number of the minerals named cannot now be identified, and the properties ascribed to many of them are purely imaginary. This is especially the case with those to which medicinal properties were ascribed, as seen in the works of Dioscorides and Galen. Pliny, beside the numerous minerals of which he gives an account, refers to many more as being known; but he makes no attempt to bring them into any systematic arrangement beyond the grouping of metals by themselves, and devoting a chapter to earths, another to stones, and another to gems. The Arabian philosopher Avicenna, in the 11th century, divided minerals into 4 classes, viz., stones, salts, sulphurous or inflammable bodies, and metals. Agricola, in the early part of the 16th century, made a more elaborate division founded on the external characters, and chiefly upon the differences in the texture and tenacity of minerals. During the 17th century little progress was made toward establishing any more exact system. Minerals were now in the hands of the alchemists, and the properties next recognized in them were developed by means of their experiments. Magnus von Bromel, a Swede, and pupil of Boerhaave, introduced in his work, published at Stockholm in 1730, distinctions founded upon the effects of heat in calcining some minerals, and in causing the metals to fuse at different temperatures. Linnæus devoted much attention to the study of minerals. He observed the diversity in their crystalline forms, and in his classification, founded upon chemical and external characters, we meet with many familiar distinctions and names. Among the orders of his class of *petra*, or stones, are the calcareous,

argillaceous, and arenaceous. With the progress of chemistry improvements in the correct grouping of minerals were introduced by Henckel, Pott, and Woltersdorf of Saxony, and more especially by Wallerius, who formed his orders and genera on chemical characters alone, determining the species chiefly by their external characters. Cronstedt of Stockholm was the first to recognize the distinction between rocks and minerals, and to exclude the former from a mineralogical system. His arrangement was based on the chemical properties of minerals, and upon principles still recognized. His treatise, first published at Stockholm in 1758, was soon after translated into many European languages, and was received with great favor. Still from the imperfections of the descriptions it was found difficult to determine the mineral species; and in this respect the work of Abraham Werner on the external characters of minerals, *Von den äussern Kennzeichen der Fossilien*, published at Leipsic in 1774, exhibited a great advance beyond all that had been written before. By his clear perception of the true distinctive external characters of minerals (such only, however, as are perceptible to the eye, the tongue, or the hand), and great facility in describing them, Werner gave a new precision to the system; and at a time when nothing was known of crystallography he recognized the importance of observing the crystalline forms of the minerals, at the same time founding his principal divisions upon their "natural affinity" or chemical composition. Though his only subsequent publication was a translation of Cronstedt's mineralogy, he presented his own views so fully in the notes, that his system, taken up and expanded by his pupils, became the only one recognized for more than 40 years in all the universities of Germany. According to this, all minerals were included in 4 classes: earths, salts, inflammables, and metals, these being formed on their "fundamental constituent parts." The first was divided into the orders silicious, argillaceous, calcareous, and talcose. External characters in some instances were admitted to control the place of genera, whatever the chemical composition of the minerals; thus the diamond, sapphire, and others which contained no siliceous matter, were ranked among silicious earths. This system was adopted by Kirwan of Dublin, who in 1784 was the first in Great Britain to publish a work on mineralogy; and it was fully expounded by Prof. Jameson of Edinburgh. Mineralogy had now fairly engaged the attention of scientific men, and many were advancing it, each in his special department. Romé de Lisle appears to have been the first to fully appreciate the importance of the crystalline forms of minerals, and this branch he clearly presented in 1788 in the 2d edition of his *Cristallographia, ou description des formes propres à tous les corps du règne minéral* (4 vols. 4to.). But with the chemists the chemical composition of the minerals was esteemed their most important feature, and the crystalline forms they comparatively neglected. Klaproth of

Berlin devised new methods of analysis, and applied them with great ability to the determination of the true composition of many minerals, as also to the detection and elimination of new elements in mineral compounds. The abbé Haüy, on the other hand, devoted himself almost exclusively to the consideration of the crystalline forms. He made these the chief means of determining the mineral species, and showed how the varieties of secondary forms were traceable to an ultimate molecule of invariable shape, peculiar to each species, which being ascertained by mechanical division may serve better than chemical analysis to designate the mineral; for though the composition also may be constant, the mixture of heterogeneous substances often prevents this from being accurately found out. Crystals, which before ranked rather as the flowers of the mineral kingdom, now became its most expressive features; and though the result was the establishment of a new and important department of mineralogy, a large proportion of the mineral species were comparatively disregarded, owing to their amorphous, earthy, or compact structure. The abbé Haüy, however, did not entirely overlook the accessory aids afforded by marked peculiar physical or chemical characters, as may be seen by reference to his work, *Tableau comparatif des résultats de la cristallographie et de l'analyse chimique*, published in Paris in 1809. His arrangement of minerals, founded on their chemical composition, is in 4 classes, viz.: 1, acidiferous substances; 2, earthy substances; 3, combustible non-metallic substances; 4, metallic substances. All crystalline forms were referred to one of 6 types, to which every secondary figure could be traced by mechanical division or mathematical calculation. These types were: 1, the regular octahedron; 2, the rhombohedron; 3, the octahedron with a square base; 4, the octahedron with a rectangular base; 5, the prism with a symmetrical oblique base; 6, the prism with an unsymmetrical oblique base. This system was variously modified by different crystallographers, as Prof. O. S. Weiss of Berlin, Mohs of Vienna, Naumann of Freiberg, and others. In 1822 Haüy published his *Traité de minéralogie*, in which the classes were arranged as follows: class 1, free acids; 2, metallic substances, not having metallic appearance, containing the 8 genera, lime, barytes, strontites, magnesia, alumina, potash, soda, and ammonia, and also the silicates, which, though presented as an appendix to the class, contained more species than all the rest of the class together; 3, true metallic substances, containing 18 genera characterized by the different metals; 4, unmetallic combustible substances.—The next important treatise was the *Grundriss der Mineralogie* of Mohs, published at Dresden in 1822. This work held for a long time the first rank among mineralogical treatises, and even yet is the principal authority in Vienna and other parts of Germany in this science. Minerals were arranged in it in 8 classes. The first comprised 4 orders, viz., gas, water,

acid, and salt, and included in these such bodies as affect the taste, give no bituminous odor, and are of specific gravity below 8.8; the 2d class includes minerals which have no taste and a specific gravity above 1.8; the 3d, all fluid bodies which have a bituminous odor, and all tasteless bodies of specific gravity below 1.8. In the general scheme of the classification a succinct statement is appended to each order, defining the external characters peculiar to the genera and species it includes. Thus by noticing the lustre, specific gravity, color of the streak, hardness, and crystalline structure of any mineral, the order to which it belongs is soon ascertained. By the scale of hardness introduced by Mohs (see **HARDNESS**), great precision and value were given to this character as one of the means of identifying minerals. No test is admitted which can be applied only by changing the natural condition of the mineral, as fusion by the blowpipe, the action of acids, &c. Most of the orders belong to the 2d class, and generally have some comprehensive term to designate them, as spar, gem, pyrites, ore, &c. A single one of these orders often contains minerals differing greatly from each other in their chemical characters and composition. The genera under these have the names of common minerals, as quartz, feldspar, augite, &c., while the species are distinguished by some epithet usually descriptive of their crystalline structure or some other marked peculiarity. The mineralogical treatises of Jameson of Edinburgh, which appeared during the early part of the present century up to the year 1816, closely followed the system and nomenclature of Mohs.—Berzelius, the Swedish chemist, regarded mineralogy more exclusively as a branch of his favorite science, and ascribed the failure to recognize its dependence as a science solely upon a chemical basis to the want of familiarity with chemistry among its votaries. He considered all compound bodies as formed of electro-negative and electro-positive ingredients, the more strongly united as their respective electro-chemical forces are more opposed to each other; and in systematizing these compounds the law of definite proportions may be applied, giving to the arrangement a mathematical exactness like that already attained in chemistry. He established two great groups, the one consisting of metals which occur in a native state, and of binary compounds in which oxygen is not an element; and the 2d consisting of compounds containing oxygen. In this 2d group are numerous subdivisions, formed according to the degree of oxidation. The electro-positive oxides are succeeded by those of electro-negative character, then the hydrates, silicates, those with one, and those with many bases, the silico-aluminates, titanates, tungstates, borates, tantalates, carbonates, &c., each acid or the electro-negative element having its own division. His work was translated into French, under his direction, and published in Paris in 1819, with the title *Nouveau système de minéralogie*.—

Hauy's system was generally received in France until the appearance of Boudant's *Traité de minéralogie* in 1824. It then gave place to the chemical system of this author, which prevailed for many years afterward. Recognizing the insufficiency of physical characters either for determining species or grouping these into genera, Boudant has selected the electro-negative principle in minerals as the basis for forming his genera, and distributed these into 3 great classes, which also are distinguished wholly by their peculiar chemical properties. The first, called *gasolytes*, contain as an electro-negative element bodies, gaseous, liquid, or solid, susceptible of forming stable gaseous combinations with oxygen, hydrogen, or fluoric acid. Under this are ranged the family of silicious minerals, that of the carbonides, including carbon, the carburets, carbonites, carbonates, and sulpho-carbonates; of the chlorides, consisting of the hydrochlorates, chlorurets, and chloro-silicates; and other families similarly formed. The second class, called *leucolytes*, contains as an electro-negative principle solid bodies which give white solutions with acids, and are not susceptible of forming permanent gases. This includes the families of aluminides, magnesides, antimonides, stannides, hydrygarides, argyrides, and others. The 3d class, called *chroicolytes*, contains as an electro-negative element bodies which give with acids colored solutions, and cannot be resolved into permanent gases. This includes all the metals and oxides not embraced in the 2d class. In this arrangement the claims of mineralogy to a natural method of classification are entirely disregarded; and the metallic compounds especially are separated from each other in a manner which renders their determination difficult without an acquaintance first made with their chemical properties.—The system of Brongniart, which succeeded that of Boudant, also recognizes the chemical composition as the most important basis of classification. As this changes, the physical properties change with it, and these moreover may be seen under various modifications, while the composition remains the same. But instead of grouping the species into genera according to their electro-negative element alone, he adopts a mixed method, applying this principle only to the ancient class of earthy salts and stones, or silicates, and arranging the metallic minerals according to the electro-positive element—according to the metallic base rather than the acid. By this double method, in the one class, he avoids bringing such diverse compounds as alum, sapphire, and feldspar into juxtaposition, merely because their base, alumina, is the same, and in the other all the advantages of a natural classification are secured, and the combinations of each metal forming its ores are conveniently grouped together under one genus, which is the metal itself. The first class of his great division of inorganic bodies (which does not include the mineral coals and other substances derived from organic bodies) is called

gasolytes, and comprises 20 elements, one or other of which is found in every mineral compound, and which may be termed mineralizers. Arranged according to their electro-negative order, they are as follows: oxygen, hydrogen, sulphur, selenium, chlorine, iodine, bromine, fluorine, carbon, boron, silicon, titanium, tantalum, tellurium, arsenic, phosphorus, antimony, tungsten, osmium, mercury. The second class, *métaux natifs*, is made up of the true metals and their compounds only. The third class, called *minéraux hétéropeux* (earthy and alkaline bases), comprises two orders. In the first are found the hydrates, oxides, quartz, corundum, and other minerals not containing an acid; the 2d order is made up of salts arranged according to their electro-negative rank, as chlorides, fluorides, phosphates, arseniates, nitrates, sulphates, carbonates, borates, boro-silicates, fluo-silicates, silicates, aluminates.—In 1840 a work on crystallography was published by M. Gustav Rose in which minerals were arranged in 6 systems according to their crystalline forms, and in each of these their distribution into genera and species was according to the chemical system of Berzelius as proposed in the 2d edition of his treatise on the blowpipe. A similar mixed method characterizes the *Krystallo-chemisches Mineral-System* of Gustav Rose, published in 1853; but the crystallographic feature is made much less prominent. In it minerals are divided into the following 4 classes: 1, simple bodies; 2, compounds of sulphur, selenium, tellurium, arsenic, and antimony; 3, compounds of chlorine, fluorine, iodine, and bromine; 4, oxygen compounds. The species, determined by their chemical composition, are grouped into genera according to their crystalline forms. The 4th class, from the great number of its members is necessarily subdivided. The two principal divisions are: 1, of binary compounds; and 2, of double or many times binary compounds; and in each of these are formed groups based on the relative proportion between the atoms of oxygen of the base and of those in the acid, as expressed by the formulas respectively, R^2O , R_2O , R^2O^2 , RO^2 , RO^3 , for the first division; and in the 2d by the formulas resulting from the combinations of these, as R^2O^2 , R^2O^3 , RO^2 , R^2O^4 , RO^4 . Each of these subdivisions is again divided into groups distinguished by their crystalline forms, and the system of subdivision is continued on chemical principles until the species is at last left by itself.—The most complete descriptive mineralogy of the present day is the *Traité de minéralogie* of A. Dufrénoy, the 2d edition of which was published in Paris in 1856 (5 vols. 8vo.). The author recognizes natural groups in the mineral kingdom in some of which, as the metals, the peculiar characters are derived from the bases, and in others, as the silicates, from the acids; and he therefore adopts the mixed system of Brongniart as more in harmony with the natural properties of minerals, and also more convenient for study. Even when considered in relation to their crystalline forms, he regards it quite as philosophical

to classify minerals according to their bases as according to their acids; for though forms belonging to the same crystallographic system often accompany the same acid in many of its combinations, there are so many exceptions to this that it cannot be regarded as a law; and on the other hand there are many instances of isomorphous acids, which replace each other in all proportions. Moreover, if all crystals, artificial as well as natural, be considered, there will be found quite as much reason from the great number of these instances for grouping them with relation to the bases as the acids. The metals and the silicates thus form two distinct classes, and a third presents itself of the acidiferous substances; but these may conveniently be divided into two, the one containing alkaline bases and soluble in water, and the other the earths and the alkaline earths. Two more classes complete these divisions, making 6 in all; and the whole are thus arranged: I. Simple bodies, 25 in number, electro-negative, never acting as bases with substances of the other classes, and one or other of them present in every binary compound; forming permanent gases, either singly or in combination with other bodies of the same class. Each constitutes a genus. They are as follows: 1, oxygen; 2, hydrogen; 3, nitrogen; 4, chlorine; 5, bromine; 6, iodine; 7, fluorine; 8, carbon; 9, boron; 10, silicon; 11, titanium; 12, tantalum; 13, sulphur; 14, selenium; 15, arsenic; 16, phosphorus; 17, vanadium; 18, antimony; 19, tellurium; 20, mercury; 21, molybdenum; 22, tungsten; 23, chrome; 24, osmium; 25, rhodium. Although thus classified, the description of the genera titanium, antimony, tellurium, mercury, molybdenum, osmium, and rhodium is to be found in the work itself among the metals, with which the various species derived from these substances have the greatest analogy in their external characters. II. Alkaline salts, soluble in water, and having a decided taste, which is usually characteristic. The class contains the 3 genera: 26, ammonia; 27, potash; 28, soda. III. Earths and alkaline earths, substances of stony appearance, colorless or milk white, none hard enough to scratch glass except corundum; specific gravity of all between 2.7 and 4.6, except tungstate of lime, which is 6; nearly all are infusible before the blowpipe, and all fail to be reduced by its action. There are 6 genera: 29, barytes; 30, strontia; 31, lime; 32, magnesia; 33, yttria; 34, alumina. IV. Metals, comprised in two divisions, the 1st containing the native metals and natural alloys, and the 2d combinations of the metals with oxygen or acids. The genera are as follows: 35, cerium; 36, manganese; 37, iron; 38, cobalt; 39, nickel; 40, zinc; 41, cadmium; * 42, lead; 43, tin; 44, bismuth; 45, uranium; 46, copper; 47, silver; 48, gold; 49, platinum; 50, iridium; 51, palladium. V. Silicates, minerals commonly known by the an-

cient as stones, on account of their stony appearance. They are arranged in two groups, the anhydrous and hydrated silicates. The species belonging to the former are hard, insoluble, and attacked with difficulty by the acids. Those of the latter are tender and dissolve readily in acids. The specific gravity of the class is between 2.3 and 3.6; and few reach this extreme. The genera are as follows: 52, aluminous silicates, Al Si ; 53, hydrated aluminous silicates, $\text{Al Si} + \text{Aq}$; 54, silicates of alumina, and lime or its isomorphs, $\text{Al Si} + (\text{Ca, Mg, Fe, Mn}) \text{Si}$; 55, silicates of alumina and alkalis and their isomorphs, $\text{Al Si} + (\text{K, Na, Ca}) \text{Si}$; 56, hydrated silicates of alumina with alkalis, lime, and isomorphs, same formula + Aq ; 57, silicates not aluminous, R Si ; 58, silico-aluminates,* $\text{Al Si} + \text{R Al}$; 59, silico-fluates, $\text{Al Si} + \text{Al Fl}$; 60, silico-borates, $\text{Ri Si} + \text{R Bo}$; 61, silico-titanates, $\text{R Si} + \text{Ti Si}$; 62, sulpho-silicates, R Al, Si, Su ; 63, aluminates, R Al . VI. Combustibles. Genera: 64, resins; 65, *suijs de montagne*, "mountain tallow," a variety of combustible wax-like substances found with lignite; 66, bitumens; 67, coals and peat.—All these systems of classification, except that of Mohs, while they afford to mineralogists a convenient method of arranging their collections, and are instructive by suggesting the relations existing between those of the same groups, are deficient in one important object, which is the presenting to pupils the means of identifying species with which they are not familiar. They even presuppose an acquaintance with the chemical composition of the mineral before it can be referred to its proper place. To meet this objection Dufrénoy arranged several sets of tables. One contains the various crystallized minerals grouped according to their crystalline forms, by which, when that of an unknown mineral is observed, further search for its name is limited among the few others that possess the same form. Another set of tables presents the minerals arranged according to their mode of texture, each group being distinguished by certain peculiarities of fracture or structure, with subdivisions depending on the kind of lustre. Another useful aid for attaining the same object is the application to mineralogy of the method introduced by De Lamarck for determining botanical species, and named by him *dichotomique*, which consists in presenting, in the table prepared for the purpose, two opposite qualities, one of which being selected as belonging to the species, the number of another pair is indicated, to which the mineral is next referred, and so on, until at last the investigation is terminated by reaching the name of the species. This method is based as much as possible on external characters, the chemical properties being brought in when the former are inadequate for the determination.—Numerous other treatises of importance have been published in Europe upon this science within a few years past; and among these none is more

* In a table of the classification at the end of vol. iv., cadmium appears in the first class, thus arranged: 18, tellurium; 19, cadmium; 20, antimony.

* Genus omitted in the final table.

worthy of mention than the *Lehrbuch der chemischen und physikalischen Geologie* of Gustav Bischof, which has already been referred to in the article GEOLOGY. It is not a descriptive work on minerals, but a profound treatise upon their properties and chemical characters, and stands in the same relation to mineralogy as a work on vegetable physiology does to botany. The treatise by H. J. Brooke and W. H. Miller, published in 1852 under the title of "Elementary Introduction to Mineralogy," and based upon the excellent "Elementary Treatise on Mineralogy" of William Phillips of 1816, 1823, and 1837, is also a work of great importance.—In the United States mineralogy had been but little cultivated before the beginning of the present century. A few collections of minerals had been brought from Europe, but the treatises of Kirwan and Jameson were almost the only works that could be consulted with reference to them, and very few persons were acquainted with these. In 1816 Prof. Parker Cleaveland, of Bowdoin college, published "An Elementary Treatise on Mineralogy and Geology," which was well received both in America and in Europe as a work of scientific importance, and particularly useful for the information it afforded respecting American minerals. The author, following the general plan of Brongniart at that time, sought to unite with the precise descriptive language of the system of Werner the chemical classification of the French mineralogists. Notwithstanding the very faulty arrangement of Haüy which he adopted, his work continued to be for many years highly popular, and indeed almost the only one in use by American mineralogists. A second edition of it appeared in 1822. Ten years afterward Prof. Charles U. Shepard of New Haven published the first part of his "Treatise on Mineralogy," and in 1835 the second part. He adopted the arrangement of Mohs with little variation, making the natural history or external characters as far as possible the means of determining the species. He however appended a table in which the minerals were also arranged according to their chemical affinities. Francis Alger of Boston republished the then recent "Treatise on Mineralogy" prepared by Robert Allan from Phillips's "Mineralogy," enlarging it by numerous notices of American minerals and of recent discoveries. Like the last named work, it was particularly interesting for presenting many new facts in the development of the mineralogy of the United States.—Prof. James D. Dana of New Haven commenced in 1837 the publication of his treatises upon mineralogy by the issue of the first edition of "A System of Mineralogy, including an extended Treatise upon Crystallography." In the works of this author the department just named is most fully treated, and some of his views are presented in the article CRYSTALLOGRAPHY in this cyclopædia. Prof. Dana adopted the classes and in general the orders of Mohs as the basis of his classification in this work. He introduced two very useful tabular classifications for aiding

the learner in determining the names of minerals. One includes crystallized minerals, in which the classes, arranged according to the systems of classification adopted, are divided into two sections distinguished by their unmetallic or metallic lustre; and in these the species are distributed in the order of their hardness, under the heads of hardness, gravity, cleavage, lustre, color, diaphaneity, &c. The second arrangement is independent of crystallization; and the species—presented in the three great classes of *epigæa*, which include the gases, unmetallic liquids, and soluble minerals; *catagæa*, the insoluble minerals of the rocky strata; and *hypogæa*, or species of vegetable or animal origin—are subdivided into sections and subsections depending on their metallic or unmetallic lustre, and the color or want of color of their streak. This work has passed through several editions, each of which has been modified as the science has been more and more developed. The system of classification adopted in the 4th edition (1854) seeks to combine with the chemical system of Berzelius the arrangement according to crystalline forms. The progress of the science, the author remarks, has afforded the means of giving greater precision and simplicity to this arrangement, until now it seems entitled to become the authorized method. The following are the leading divisions: I. Native elements, including three groups, viz.: 1, hydrogen group, or those elements whose oxides are represented by the formulas RO , R_2O_3 , or RH_4 ; 2, arsenic group, oxides represented by RO_3 or R_2O_5 ; and 3, carbon group, including diamond, coals, and graphite. II. Combinations with elements of the sulphur and arsenic sections which compose the arsenic group; these are arranged under the heads of binary and double binary compounds. III. Fluorides, chlorides, bromides, iodides; this also is subdivided like the preceding class. IV. Oxygen compounds, with the same subdivisions, and including the silicates, titanates, columbates, tungstates, sulphates, phosphates, carbonates, and other related groups of salts. V. Organic compounds, as resins, &c. In this work the subject of isomorphism or homeomorphism, the principle according to which analogous elements, bases, or acids replace one another in compounds without an essential change in the crystalline form, is treated with particular care and fulness. The "Manual of Mineralogy" of the same author was first published in 1848, and a 6th edition in 1884. It contains useful tables for the determination of minerals; and the arrangement of the species is based on the following classes: I., gases containing hydrogen or nitrogen; II., water; III., carbon and compounds of carbon; IV., sulphur; V., haloid minerals, compounds of the alkalis and earths with the soluble acids or water; VI., of their metals with chlorine or fluorine; VII., earthy minerals, silica and silicious or aluminous compounds of the alkalis and earths; VIII., metals and metallic ores, exclusive of the metals of the alkalis and earths.

MINERSVILLE, a village of Schuylkill co., Penn., on the W. branch of the Schuylkill river and on the Mine Hill and Schuylkill Haven railroad, 4 m. W. from Pottsville, and 66 m. N. E. from Harrisburg; pop. in 1850, 2,951. It is surrounded by hills containing rich mines of anthracite. There were in 1850 a flour mill, saw mill, iron foundry, car factory, and 4 churches (Baptist, Episcopal, Methodist, and Roman Catholic).

MINERVA. See **ATHENA**.

MINGRELIA, a province of Asiatic Russia, in the lieutenancy of the Caucasus, bounded N. by the Circassian districts, E. by Imeritia, S. by Gooriel, S. W. by the Black sea, and N. W. by Great Abkasia; area about 2,365 sq. m.; pop. 70,000. The surface is generally mountainous, but slopes gradually to the S., particularly toward the Rion, its principal river. The climate is warm and damp, and fevers are prevalent. The soil is exceedingly fertile, and vegetation rapid. The mountains are covered with magnificent forests, and much good land lies waste. Tobacco, rice, and millet are raised, and a good deal of silk, honey, and wine produced. The province is without any internal improvement, and has a savage and deserted appearance. The inhabitants are generally inferior in appearance to the mountaineers of the Caucasus. The dominant religion is that of the Greek church, and the province is divided into 3 dioceses. Mingrelia nearly corresponds with the ancient Colchis; it became subject to Russia in 1803, but is governed by its own prince, who is called Dadian. On the W. coast of the province the Russians have the forts of Redout-Kaleh and Anaklia.

MINHO (Sp. *Minho*; anc. *Minius*), a river of Spain and Portugal, which rises in the Sierra de Mondonedo, in the province of Lugo, Galicia, 9 m. S. of Mondonedo, flows first S. and then S. W., crosses the province of Orense, forms the boundary between the Spanish province of Pontevedra and the Portuguese province of Minho, and falls into the Atlantic at La Guardia, near Caminha, and about 40 m. S. of Vigo. It is about 180 m. long, and is navigable for only a short distance from its mouth, being obstructed by sand banks. Its principal tributaries are the Sil, which joins it on the left about 70 m. from its mouth, and the Tea and Avia on the right. The largest towns on its banks are Lugo and Orense in Spain.

MINHO, or **ENTRE DOURO E MINHO**, the northernmost province of Portugal, bounded N. by the Spanish province of Pontevedra, from which it is separated by the Minho, N. E. by that of Orense, E. by Tras os Montes, S. by Beira and Douro, and W. by the Atlantic; area, about 1,700 sq. m.; pop. in 1857, 488,837. It is a high table-land intersected by several mountain ridges, running in a N. E. and S. W. direction, one of which rises to the height of nearly 8,000 feet. The principal rivers are the Lima and Cavado, both of which flow into the sea, and the Tamega, an affluent of the Douro; there

are also numerous smaller rivers and streams, and the valleys are exceedingly fertile and well cultivated. The principal productions are wine, oil, flax, oranges, lemons, maize, wheat, barley, and oats. The well known wine, called port from Oporto, whence it is shipped, is almost wholly made in this province. The sea and rivers abound with fish, the capture of which affords employment to many of the inhabitants. Good macadamized roads are in progress in Minho. Capital, Braga. This province was the theatre of the principal struggles in the war of independence in the 17th century. Its population is the most intelligent and prosperous portion of the Portuguese people.

MINIATURE PAINTING, a species of painting on a small scale, executed with water colors on vellum, prepared paper, or ivory, or in enamel. The word derives its origin from the ancient practice of writing the initial letters of manuscripts in *minium* or red lead, for the purpose of distinguishing the commencement of chapters or paragraphs. These rubrics, as they were called, gradually received many fanciful adornments at the hands of the illustrators, who added rich arabesque borders, and finally delicately executed little pictures illustrating the text, to which the general name of miniature was applied. The taste for this species of ornamentation existed at a period considerably anterior to the Christian era. The ancient Egyptians illuminated their papyri with colored hieroglyphics; and from passages in Pliny, Seneca, and other classical authors, the art seems to have been familiar to the Greeks and Romans. The middle ages, however, and especially the period extending from the 8th to the 14th century inclusive, witnessed its most perfect development; and the mediæval monks in the solitude of their convents found at once an amusement and a pious occupation in embellishing their missals, breviaries, and other sacred volumes. The illumination of missals was consequently for many ages the chief form in which miniature painting was practised, although, as in the case of fresco and oil painting, subjects other than scriptural or sacred were from the outset occasionally selected. The art seems from an early period to have been divided into two branches, the professors of the first being called *miniatori* or miniature painters, or illuminators of books; and those of the second *miniatori calligraphi*, or calligraphers. "To the first class," says Mrs. Merrifield, "belonged the task of painting Scripture stories, the borders, and the arabesques, and of laying on the gold and ornaments of the MSS. The second wrote the whole of the work, and those initial letters, generally drawn with blue or red, full of flourishes and fanciful ornaments, in which the patience of the writer is frequently more to be admired than his genius." (Mrs. Merrifield's "Ancient Practice," &c., p. xxix.) Sometimes, however, the two branches were practised by the same person, and about the middle of the 14th century the exe-

cution of large illuminated initials adorned with various fanciful objects and figures such as men, animals, birds, flowers, &c., became a distinct occupation, the ornamentation usually extending in scrolls along the upper and lower margins of the page. The pigments employed were of the purest quality, and were applied with an admixture of white in the shape of body colors, the vehicle being some glutinous substance sufficiently diluted in water to leave the surface of the vellum dull and lustreless. The Vatican collection of MSS. contains the most ancient specimen of classical calligraphy extant, a Virgil of the 4th or 5th century with 50 miniatures, beside many others of a somewhat later date; and fragments of an illuminated Homer, which may also be ascribed to the 4th or 5th century, are preserved in the Ambrosian library at Milan. The Byzantine artists particularly excelled as illuminators, and their MSS. exhibit intricate arabesques of mixed foliage and animals, and the richest architectural fancies in the margins, although many of these are said to be repetitions of Romano-Christian works of the 5th and 6th centuries. The most elaborate exemplar of the school is the Menologium, or calendar executed A.D. about 1000 for the emperor Basil II., and which, notwithstanding one half of it is wanting, contains 480 miniatures on a gold ground, illustrating scenes from the lives of Christ and the saints, the history of the church, &c. The period extending from the middle of the 11th to the commencement of the 13th century was the richest in the history of the Byzantine school. Afterward the art rapidly deteriorated among them. Under the early Carolingian kings, the transcription and embellishment of manuscripts were greatly encouraged; and the Bibles of Charles the Bald, preserved in the imperial library at Paris, and in the Benedictine monastery of St. Calixtus in Rome, are admirably illustrated. The English MSS. are not inferior to the continental, and the Benedictional of St. Ethelwolf, executed in 968-7 by Godeman, a monk of Hyde abbey, is considered one of the purest specimens of early English art. The celebrated Bedford missal, executed in France for John, duke of Bedford, regent of France under Henry VI., and now in the British museum, is one of the latest and richest specimens of the art of MS. illumination. Among the most celebrated of the *miniatori*, who were also equally if not more celebrated in other branches of art, may be mentioned Simone Memmi, Giotto, Fra Angelico da Fiesole, Jan van Eyck, Squarcione, Girolamo dai Libri, Hans Hemling or Memling, and Giulio Clovio. Hemling was perhaps the best of all the illuminators; and of the industry of Giulio Clovio a memorable example is extant in his "Office of the Virgin," now in the royal library of Naples, the 28 miniatures of which are said to have occupied him 9 years. With the invention of printing the occupation of the illuminator and calligrapher departed, although of late years the practice of embel-

lishing books with illuminated borders and fanciful initials has again come into vogue. But modern invention has substituted for the toilsome efforts of the *miniatori* of the middle ages, various rapid processes for printing designs in colors, of which Owen Jones's publications afford some happy illustrations.—The term miniature painting is now applied almost exclusively to small portraits executed on thin sheets of ivory, which, on account of the semi-transparency of its texture, is preferred to any other material. This property of the ivory renders it necessary for the back to be protected by something perfectly white, as the effect of the painting might otherwise be injured by any dark substance behind showing through. Miniatures on ivory seldom exceed a few square inches in size. When larger sheets are required, the elephant's tusk is sawn round its circumference, and the ivory is steamed and flattened by hydraulic pressure, and finally mounted for use with India rubber on a panel of mahogany or other hard wood. From the tender and romantic associations frequently connected with miniatures, as well as their historical interest, they have commanded the highest talent in the best ages of art. In England the art has been cultivated by an eminent line of artists from Holbein downward, embracing such names as Nicholas Hilliard, Isaac and Peter Oliver, Samuel Cooper, Hoskins, Flatman, Gibson, Cosway, Ross, Newton, Thorburn, &c. whose works are invaluable for the likeness they afford of distinguished public characters. According to Dr. Waagen, "in no department have the English artists attained so high a state of perfection as in this." Under the first empire the French had many excellent miniaturists, including Isabey, who not only painted on ivory portrait pieces containing many figures, but attempted with success historical subjects, Augustin, Guérin, Saint, Mme. de Mirbel, &c. The most eminent American miniature painter was Malbone, whose works are executed with great delicacy, and after the lapse of many years retain much of their original freshness. Among others who have succeeded in this department of the art are Charles Fraser of South Carolina, Henry Inman, and Staigg, the last of whom is among the most eminent of living artists in the department. Of late years the introduction of colored or retouched photographic likenesses has somewhat interfered with the profession of the miniature painter, although portraits painted wholly by hand, and which catch their expression from the genius of the artist, can never be superseded by a mere photograph. Photography, kept distinct, and regarded only as an auxiliary to the miniature painter, rather than the latter by the data it affords for greater accuracy of drawing and proportions. (See ENAMEL.)

MINIÉ, CLAUDE ÉTIENNE, a French officer, inventor of the rifle bullet which bears his name, born in Paris about 1810. At an early age he entered the army as a private soldier.

and, after serving several campaigns in Algeria, reached the rank of captain of foot chasseurs. His inventive faculty now began to be exercised with improvements in the construction of firearms and projectiles; and so completely was he occupied with the subject, that, on the supposition that he was losing his efficiency as a military officer, his dismissal was determined upon. Through the influence of the duke de Montpensier he was retained in the service, and encouraged to continue his mechanical labors; and gradually several of his improvements in rifle balls, cartridges, and gun barrels were adopted by the artillery board. In 1849 he was decorated with the cross of the legion of honor; in 1852 he was promoted to the rank of major on the retired list, and soon after was appointed *chef du tir*, or instructor in the use of firearms at Vincennes, where he now resides. The rifle bullet invented by him consists of an elongated cylinder, conical in front and hollow behind, and fitted with a cap of thin iron, which, by filling the grooves of the barrel as the ball is forced through, gives to the latter a precision and range of flight hitherto unknown to the science of gunnery. This was the first effectual introduction of the principle of expansion into the manufacture of firearms. Minié has never taken out a patent for his invention, and has refused very advantageous overtures from the Russian government to establish himself at St. Petersburg in its service. Napoleon III. has presented him with 20,000 francs. Nearly the whole French army and many other bodies of European troops are provided with Minié rifles and bullets.

MINISTER, a high officer of state intrusted with the administration of national affairs. Collectively, the persons who constitute the administration are called in Europe the ministry, and also the cabinet. In Great Britain, of late years, the ministry has been formed by some eminent party leader who has the confidence of the house of commons, and is authorized by the sovereign to organize a cabinet. The person thus charged with the task selects from his party or from those favorable to his policy the members of the ministry, taking himself generally the post of premier or prime minister, and commonly the office of first lord of the treasury. The other principal ministers are the lord chancellor, the three secretaries of state for home, colonial, and foreign affairs, the secretary at war, and the chancellor of the exchequer. Beside these officials, the British cabinet in 1860 comprised the lord privy seal, the chief secretary for Ireland, the postmaster-general, the president of the board of trade, the president of the council, the chancellor of the duchy of Lancaster, the first lord of the admiralty, the president of the poor law board, and the Indian secretary. The composition of the cabinet varies in different administrations, and some cabinets comprise officers who are not in others. Thus, in addition to those already mentioned, the paymaster-general, the

master of the mint, and the commander-in-chief of the army have at one time or another been members of the cabinet since 1830. The cabinet is not a body recognized by English law, and orders and proclamations are therefore issued, not in its name, but in that of the privy council, a much larger body which was formerly the adviser of the crown in all affairs of state. It was in the reign of William III. that the distinction of the cabinet from the privy council, and the practical exclusion of the latter from all business of state, became fully established. The ministry should contain members of both houses of parliament. "The ministry is, in fact," says Macaulay, "a committee of the leading members of the two houses. It is nominated by the crown; but it consists exclusively of statesmen whose opinions on the pressing questions of the time agree in the main with the opinions of the majority of the house of commons." When the house of commons by a decisive vote on a test question shows that it no longer approves the policy of the cabinet, the ministers are expected to resign and make way for a new cabinet.—The executive government of France is divided into 10 departments or "ministries," viz., of state, justice, foreign affairs, interior, finances, war, marine, public instruction and worship, agriculture, commerce, and public works, and Algeria and the colonies. The heads of these departments are members of the cabinet. The cabinet of the president of the United States consists of the secretaries of state, treasury, war, navy, the interior, and of the attorney-general and postmaster-general. These hold office at the pleasure of the president, by whom they are appointed subject to the consent of the senate. While in office they cannot hold seats in congress. The term minister is seldom applied in the United States to members of the cabinet, but is used, as in Europe, to designate diplomatic officers, for which see DIPLOMACY, and LAW OF NATIONS.

MINIUM. See LEAD, vol x. p. 389.

MINK, a small, fur-bearing, carnivorous mammal, found in the northern parts of America, Europe, and Asia, belonging to the genus *putorius* (Cuv.), in which are included the ermine and common weasels, and to the sub-genus *lutreola* (Wagner). The minks have one molar less on each side above and below, than the martens (*mustela*), and are therefore more carnivorous; the size is smaller, and the form more slender; the color is nearly uniform; the feet much webbed, and their pads large and naked, with the intervals not occupied by hairs. The common American mink (*P. vison*, Rich.) varies in length (from nose to base of tail) from 18 to 18 inches, the tail being 8 to 10 inches additional; the general color is dark brownish, the tail nearly black, the chin white, but not the edge of the upper jaw; some specimens are lighter, even to yellowish brown; the head is broad and depressed, with truncated snout, short round ears, small eyes and far forward, long and rigid whiskers in 4 horizontal series; body long and

vermiform, with long neck; short and stout limbs, with 5-toed feet, armed with sharp claws; tail long and cylindrical, having on each side of the under surface a glandular cavity secreting a strong musky fluid, whence the generic name; mammae 6, ventral. The under fur is soft and downy, with larger and coarser hairs intermingled; the more southern the locality, the coarser and stiffer is the fur. The mink is an active, destructive depredator in the farm yard, sometimes killing several chickens in a single night, though less sanguinary than the weasels; it now and then catches a fish on its own account, and frequently steals those left inadvertently by the angler; it feeds also on small rodents, marsh birds, frogs, and crawfish. It takes up its residence on the borders of ponds and small streams, especially near rapids and waterfalls; it is an excellent swimmer and diver, and a good runner; it rarely climbs trees like the martens, unless when hotly pursued; when killed in the water, it almost always sinks. It is readily caught in box or steel traps, or in dead-falls, baited with the head of a bird; it is very tenacious of life, and most active at night. In northern New York, the breeding season begins toward the 1st of March, while the snow is on the ground; the young, 5 or 6 in number, are born about the end of April; when taken young, it is easily domesticated. The fur of the mink was formerly considered hardly worth collecting, a skin selling for about 50 cents; but since the caprice of fashion has brought this fur into vogue, they are worth from \$1.50 to \$2.50 apiece, according to color and quality; the fur is fine, but shorter and less lustrous than that of the pine marten or American sable. It is very generally distributed in North America, from lat. 70° N. to Florida, and from ocean to ocean. Some specimens from the West are larger than the average. In the northern states there is a smaller and blacker mink (*P. nigrescens*, Aud. and Bach.), by some considered a mere variety; the fur is dark and remarkably soft, and considerably more valuable than that of the common mink.—The European mink (*P. lutreola*, Cuv.) is of smaller size, darker colored, with less bushy tail, and the edges of the upper lip white; it is a rare animal, with the same habits as the American species, and its fur is more highly esteemed; indeed it is often sold to the inexperienced for sable, and that of the American mink is generally called by furriers American sable, though the latter belongs to the genus *mustela* and is properly a marten.

MINNESINGERS (Germ. *Minna*, love, and *Sänger*, singer), a school of German poets which sprang into existence in the latter half of the 12th century, and flourished until near the close of the 18th. Their themes were amatory and heroic, and were treated in much the same manner as those of the troubadours of Provence, though in a more earnest spirit and after a purer ideal conception of love. For an account of the characteristics of the school and its chief exemplars, see GERMANY, LITERATURE OF, vol. viii. p. 218.

MINNESOTA, one of the north-western states of the American Union, and the 19th admitted under the federal constitution, situated between lat. 43° 30' and 49° N., and long. 89° 29' and 97° 5' W., having an extreme length N. and S. of 880 m., and a breadth varying from 183 m. in the middle to 262 m. on the N. line and 387 m. near the N. line; area, 81,259 sq. m., or 52,005,760 acres, being 2.73 per cent. of the total area of the United States. It is bounded N. by British America, the dividing line being formed W. of the Lake of the Woods by the 49th parallel, and E. of that lake by Rainy Lake river, Rainy and other lakes, and Pigeon river; E. by Lake Superior and Wisconsin, from which it is separated by a line drawn due S. from the first rapids in the St. Louis river to the St. Croix river, and by the St. Croix and Mississippi rivers; S. by the state of Iowa; and W. by Dacotah, from which it is divided by the Red river of the North, the Bois des Sioux river, Lake Traverse and Big Stone lake, and a line drawn directly S. from the outlet of the last named lake to the Iowa boundary. The state is divided into 68 counties, viz.: Aitkin, Anoka, Becker, Benton, Blue Earth, Breckinridge, Brown, Buchanan, Carlton, Carver, Cass, Chisago, Cottonwood, Crow Wing, Dacotah, Davis, Dodge, Douglas, Faribault, Fillmore, Freeborn, Goodhue, Hennepin, Houston, Isanti, Itasca, Jackson, Kanabec, Kandiyohic, Lake Le Sueur, McLeod, Manomin, Martin, Meeker, Mille Lacs, Monongalia, Morrison, Mower, Murray, Nicollet, Nobles, Olmsted, Otter Tail, Pembina, Pierce, Pine, Pipestone, Polk, Ramsey, Renville, Rice, Ripley, Rock, St. Louis, Scott, Sherburne, Sibley, Stearns, Steele, Todd, Toombs, Wabashaw, Waseca, Washington, Watonwan, Winona, Wright. The principal cities and towns are St. Paul, the capital, St. Anthony, Minneapolis, Stillwater, Winona, Red Wing, Hastings, Wabashaw, Lake City, Anoka, Cloud, Shakopee, St. Peter, Mankato, Faribault, Rochester, and Chatfield.—According to the census of 1850, Minnesota contained 60,772 inhabitants, of which number 6,038 were white and 39 colored persons. In 1855 the population was estimated to be 68,812. By an act of congress passed Feb. 27, 1857, the secretary of the interior was directed to institute a census of the territory previous to its admission into the Union, and the enumeration thus initiated gave the following results: white persons 149,820 (males 87,395, females 62,425) colored persons 272 (males 144, females 128) total 150,092, or about 2 to the square mile, constituting 32,536 families. The number of legal voters was 49,130, of whom 26,392 were native and 22,838 naturalized. By the census of 1860 the population in 57 counties was 176,535.—Lying nearly at the centre of the continent, Minnesota occupies the summit of the interior plain of North America, formed by the conterminous basins of the Mississippi, St. Lawrence, and the rivers flowing into Lake Winnipeg, and at once encloses the head waters

and the navigable limits of the three great converging river systems of the continent. A group of low sand hills in N. E. Minnesota, formed by huge deposits of drifts overlying a local outcrop of the primary and metamorphic rocks, which terminates the Superior basin on the west, forms the "Heights of Land" between the waters which flow respectively into the gulf of Mexico on the south, the Atlantic ocean on the east, and Hudson's bay on the north. The Heights of Land rise by scarcely perceptible slopes from the general level, in no instance higher than 1,680 feet above the sea, which is not more than 600 feet above the average elevation of the country. These hills are commonly flat at the top, varying in height from 85 to 100 feet above the surrounding waters. The principal group of these drift hills is subdivided into several ramifications. A prominent spur extends in a southerly direction from the Itasca crest of the Mississippi for perhaps 150 miles, known as the Leaf mountains and the Coteau du Grand Bois of Nicollet, and forms a low dividing ridge between the waters of the Mississippi and Red rivers. The crest of the dividing ridge between Lake Superior and the Mississippi is not more than 1,400 feet high; and the highest of the trap summits north of the lake is but 1,475 feet. Lake Superior is 641 feet above the sea. With this exception the surface of the country is generally an undulating plain, with an average elevation of nearly 1,000 feet above the sea, and presents a succession of small rolling prairies or table lands, studded with lakes and groves, and alternating with belts of timber. Two thirds of the surface slopes S. E. with the waters of the Mississippi, the northern part of the state being nearly equally divided between the alluvial levels of the Red river valley on the north-west and the broken highlands of the north-east, which are mainly drained by the precipitous streams which flow into Lake Superior and the Rainy lake chain.—The principal rivers are the Mississippi, which originates in Lake Itasca lying in the extreme western elbow of the Heights of Land, and flows S. E., 797 m. of its course belonging to Minnesota, of which 134 forms the E. boundary; the Minnesota, which traverses the lower part of the state in a S. E. and N. E. direction, and falls into the Mississippi after a course through the state of 334 m.; the Red river of the North, which rises in Elbow lake, and, flowing through several lakes, runs in a S. W. direction, then turning to the N. forms the W. boundary for 379 m.; and the St. Croix river, which rises in Wisconsin, forms 129 m. of the E. boundary, and falls into the Mississippi. In the N. E. part is the St. Louis river, which falls into Lake Superior, and is important as the first link in the chain of lakes and rivers of the St. Lawrence system; and in the S. W. are the head waters of the Des Moines. All the rivers have numerous branches. The navigable waters within the state have a total shore line of 2,746 m., and a water line of 1,582 m. Along the banks of the

Mississippi and of some other rivers are high bluffs, forming one of the most interesting and characteristic features of the scenery. Minnesota is distinguished for the number and beauty of its lakes, which present every variety in size, outline, and situation. Their waters are generally sweet and clear, lying on rocky or pebbly bottoms, and abounding in fish. The largest of these lakes are the Lake of the Woods, Rainy, Namekan, Bois Blanc, Vermilion, Swan, Sandy, Winibigoshish, Leech, and Mille lakes in the N. E., Red lake in the N. W., Big Stone, Benton, Sauk, and Swan in the W. and S. W. Many of the lakes have an area of from 100 to 400 sq. m.—Notwithstanding the great area covered by this state, the rock formations it contains, so far as they have been explored, appear to be limited almost exclusively to the azoic and lower protozoic groups; and over the greater part of the state these are concealed beneath the diluvial deposits which make the superficial covering of the boundless rolling prairies. The N. W. coast of Lake Superior is made up of metamorphic slates and sandstones, intermingled with grits of volcanic origin and other bedded traps and porphyries. These are intersected by frequent dikes of greenstone and basalt; and among them are occasional deposits of red clay, marl, and drift. Behind this group are traced westward, along the northern boundary of the state, formations of hornblende and argillaceous slates, succeeded by granitic and other metamorphic rocks. These groups extend S. W. into the central portions of the state. Along the southern boundary the devonian formation is found in the extreme west; the Niagara limestone succeeds this toward the east, and next occurs the Galena limestone, and then the Trenton limestone and the upper or St. Peter's sandstone, which overlies the Potsdam sandstone. These sandstones crop out up the valley of the Mississippi, nearly as far as Fort Snelling, when the lower silurian limestones, which on both sides the river lie behind and over the sandstones, meet in the valley and form the bluffs of the rivers. They are traced up the Minnesota river, curving round and almost reaching the southern boundary of the state again, and cutting off the continuation of the higher groups further northward. Thus throughout the state there appears to be no room for the carboniferous group, so that no coal may be looked for. The lead-bearing rocks traced from the Iowa line are of little extent, and probably of little importance.—The soil is fertile, $\frac{2}{3}$ of the surface being well adapted to the cultivation of all the cereals and roots of the temperate zone. It is composed generally of a dark, calcareous loam, abounding in organic and saline ingredients, and is retentive of moisture. In climate Minnesota is favored beyond most lands in the same latitude on the continent. The winters are cold, but clear and dry, and the fall of snow is light; the summers are warm, with breezy nights, during which occur most of the rains; and the general

purity of the air and the salubrity of its climate recommend it for the residence of invalids. The country, especially above lat. 46°, is well timbered; pine forests extend far to the N., and birch, maple, aspen, ash, and elm abound. A large forest of hard wood varieties known as the Big Woods, and called Bois Franc by the early French settlers, extends over the central portion of the state W. of the Mississippi, and covers an area of about 4,000 sq. m. On the river bottoms are found basswood, elm, aspen, butternut, ash, birch, maple, linden, balsam fir, and some oaks; and in the swamps tamarack, cedar, and cypress. Among the wild animals are the elk, deer, antelope, bear, wolverene, otter, muskrat, mink, marten, raccoon, and wolf. The buffalo is no longer found E. of the Red river. Of birds, there are the golden and bald eagles, grouse, pheasant, partridge, hawk, buzzard, owl, quail, plover, lark, and many smaller kinds. There are also the pelican, tern, sheldrake, teal, loon, wild geese, wild ducks, and other water fowl. The waters contain pike, pickerel, bass, whitefish, muskelonge, catfish, trout, and other varieties of fish.—Many natural objects of interest are found throughout the state. The Mississippi, studded with islands and bordered by high bluffs, presents a succession of most picturesque scenes. Mountain island, with an elevation of 428 feet; Maiden's rock, celebrated in Indian tradition, on an expansion of the river called Lake Pepin, about 400 feet high; and La Grange mountain on the same lake, are all notable for their picturesque character. St. Anthony's falls, celebrated as much for their surrounding scenery as for the descent of the waters, which have a perpendicular fall of only 16½ feet, are further up the river, and promise from the abundant water power they afford to become a most important manufacturing site. A few miles beyond, between Minneapolis and Fort Snelling, are the Minnehaha falls, a romantic and beautiful cascade with a perpendicular pitch of 45 feet, flowing over a projecting rock which permits a passage underneath. Brown's falls, which have a perpendicular descent of 50 feet, and including the rapids of 100 feet, are situated W. of the Mississippi, on a narrow stream which is the outlet of several small lakes. There are also falls or rapids on the St. Croix, about ½ m. below which is a noted pass through which the river has forced its way, called the Dalles of St. Croix, and others of less note on various streams. About 2 m. from St. Paul is Fountain cave, an excavation in the white sandstone, with an entrance about 15 feet in diameter opening into a chamber 150 feet long and 20 wide. The cave has been explored for 1,000 feet without reaching the termination.—Until the year 1845 Minnesota was the home of the Indian, the Chippewas and Sioux; and the only representatives of civilization within the country were the trappers and traders, the lumbermen on the St. Croix, and a few missionaries of religion. The succeeding years have seen a tide of immigration

represented by thousands and tens of thousands annually, so that at the present time there cannot be fewer than 200,000 white inhabitants. On June 1, 1850, cultivation extended over 5,085 acres, and 28,846 acres were occupied but not cultivated—together valued at \$161,984; and the value of farming implements and machinery was \$15,981. The crops of 1849-'50 consisted of 1,401 bushels of wheat, 125 of rye, 30,582 of oats, 16,725 of Indian corn, 1,216 of barley, 515 of buckwheat, 21,345 of potatoes, 10,002 of beans and peas, 2,019 tons of hay, &c. The commissioner of statistics for Minnesota estimated the crop of 1859-'60 as follows: 2,500,000 bushels of wheat, 2,000,000 of Indian corn, and 2,500,000 of oats. The number of farms, according to the census of 1860, embracing returns from 57 counties, is 19,075. The live stock in 1850 consisted of 860 horses, 14 asses and mules, 607 milch cows, 655 working oxen, 740 other cattle, 80 sheep, and 784 swine; aggregate value \$92,859. According to the same census there were then in Minnesota 5 manufacturing establishments in which a capital of \$94,000 was invested, and which employed 68 hands. The raw material consumed was valued at \$24,000, and the value of the products of the year was \$57,500. The census of 1860 gives 568 manufacturing establishments. The quantity of land sold by the United states since the establishment of the land system in Minnesota has been as follows: in the year ending June 30, 1850, 1,605.41 acres; 1851, 2,831.74; 1852, 15,058.29; 1853, 5,059.15; 1854, 129,606.86; 1855, 885,595.55; 1856, 1,042,180.67; 1857, 202,010.92; 1858, 482,856.44; 1859, 190,842.57; total, 6,186,111.80 acres. These amounts are exclusive of lands entered by bounty warrants, and also of school, university, railroad, swamp, and donation lands which have accrued to the state under various acts of congress.—A considerable trade is carried on by steamers on the Mississippi, and a regular communication maintained with the East via Milwaukee and Chicago, and with the gulf states by way of St. Louis, &c. The arrivals of steamboats at St. Paul in 1844 were 41; 1845, 4; 1846, 24; 1847, 47; and 1848, 63. To this period the sole occupation of these was in the fur and Indian trade. In 1849 and subsequent years the arrivals were as follows:

Years.	No. of arrivals at St. Paul.	Month.	Days.
1849.....	85	Dec.	3
1850.....	194	"	4
1851.....	119	Nov.	9
1852.....	171	"	15
1853.....	200	"	20
1854.....	256	"	27
1855.....	560	"	30
1856.....	657	"	10
1857.....	1026	"	14
1858.....	1069	"	15
1859.....	808	"	27

In this table are included arrivals from ports within as well as without the state. The principal points of connection in the river trade without the state are La Crosse, Prairie du Chien,

Dunleith, and St. Louis, from which came $\frac{1}{2}$ of the arrivals in 1859; the remainder came chiefly from the Minnesota river, on which a smaller class of boats are employed. A small steamboat runs to Taylor's falls on the St. Croix, and above St. Anthony falls on the Mississippi to St. Cloud. Recently an important trade has sprung up between St. Paul and the Selkirk settlement on the Red river of the North, a community of 10,000 souls, consisting of farmers, hunters, and traders, connected with the Hudson's bay company. Until 1859 this trade, which is constantly increasing, was carried on by means of carts overland, of which 400 or 500 arrived annually at St. Paul. In that year, however, a small steamboat was placed on the Red river, and with the improved means of conveyance the Hudson's bay company have chosen this route for the transportation of their annual supplies, in preference to the old canoe route to Hudson's bay. In 1859 there were engaged in the commerce of Lake Superior 9 steamers and 20 sailing vessels, with a total burden of 16,200 tons. The chief commercial products of the country are wheat and oats, in the yield and quality of which it excels most other states; corn, of which it is less productive; potatoes, turnips, and other field roots; dairy products, wool, cattle, hides, furs from the north-west, pine lumber and cranberries from the north-east, and ginseng from the central forests. The exports from Aug. 20, 1859, to July 15, 1860, are stated as follows: wheat, 1,050,685 bushels; oats, 585,500; other grains, 57,100; lumber, 58,490,933 feet; logs, 71,000,000 feet; laths, 21,886,000; shingles, 6,763,000; ginseng, 208,000 lbs.; furs, value, \$160,000; cranberries, 10,800 bushels, &c.—The means of internal transit are as yet mostly limited to the rivers, affording 1,532 m. of navigation; but several roads have been built by the general and local governments, and a spirit of railroad enterprise has lately sprung up among the people. Minnesota has obtained grants of land amounting to 4,399,141 acres from congress to aid in the construction of 1,270 miles of projected railroad, on the following lines: Minnesota and Pacific railroad (main line), from Stillwater *via* St. Paul and St. Anthony to Breckinridge, 220 m., with a branch from St. Anthony *via* Anoka, St. Cloud, and Crow Wing, to St. Vincent on Red river, 400 m.; Minnesota valley railroad, from St. Paul and St. Anthony (uniting at Shakopee City), *via* South Bend, to the southern boundary in the direction of the mouth of the Big Sioux river, 190 m.; Minneapolis and Cedar valley railroad, from Minneapolis *via* Faribault to the S. boundary near Cedar river, 112 m.; Minnesota transit railroad, from Winona *via* Rochester and St. Peter to the Big Sioux river, S. of the 45th parallel, 268 m.; Root river railroad, from La Crescent to a junction with the transit railroad at Rochester, 79 m. As a further aid to the construction of these roads, a conditional loan of state credit was authorized by law, in pursuance of which bonds

to the amount of \$2,275,000 were issued and applied to grading on the various lines.—On Jan. 1, 1860, Minnesota contained 6 banks, the condition of which was as follows: Loans and discounts, \$107,193.30; due from brokers, \$45,088.20; stocks, \$225,000; specie, \$14,712.10; loss and expense account, \$4,510.78; cash items and real estate, \$7,736.91; bills of other banks, \$27,856; due from other banks, \$18,146.86; total resources, \$450,242.10. Capital, \$309,000; circulation, \$34,481; due depositors, \$58,886.88; due other persons, \$47,924.27; total liabilities, \$450,242.10.—Ample provisions have been made for education, viz.: a grant by congress of two sections of every township, or 2,888,000 acres in all, and a tax of $\frac{1}{4}$ of 1 per cent. on all taxable property, amounting in 1859 to \$89,000, for the support of common schools; a grant of 72 sections for a state university; and a state appropriation of \$15,000 in aid of 8 state normal schools. In 1859 the number of persons of school age was 42,258, and of school districts 1,016. There are union or high schools in all the principal towns, and common schools wherever the population is sufficiently compact. In 1859 a law was passed for the establishment of a deaf and dumb asylum at Faribault, and in 1858 of a state agricultural college at Glencove.—The present constitution of Minnesota was adopted Oct. 18, 1857, and the state government was organized May 22, 1858. The qualifications for voters are, that they be free white males, 21 years of age, who are or have declared their intention of becoming citizens of the United States, and who have resided in the United States 1 year, and in the state 4 months next preceding. Indians and persons of mixed white and Indian blood, who have adopted the language, customs, and habits of civilization, are also allowed to vote in any district in which they have resided for the 10 days next preceding. The legislature consists of 37 senators elected for 2 years, and 80 representatives elected for 1 year. They must be qualified voters and residents in the state 1 year, and in their respective districts 6 months next before the election. The executive consists of a governor (salary \$2,500), lieutenant-governor (\$6 a day as president of the senate), secretary of state (\$1,500), treasurer (\$1,000), and an attorney-general (\$1,000), all elected for 2 years, and an auditor (salary \$1,000) elected for 3 years. The judiciary comprises a chief justice and 2 associates forming the supreme court, 6 judges of district courts, and a judge of probate and justices of the peace in each county. All judges are elected, those of the supreme and district courts for 7 years, and the others for 2 years. The revenue of the state is derived chiefly from taxation, and in 1859 amounted to \$177,822. The valuation of property subject to tax in 1850 was \$806,437; and in 1859, \$85,564,492. The state has an absolute debt of \$250,000, and contingent liabilities to the amount of \$2,275,000, contracted on account of a loan of credit to railroad companies.—Though of so recent settlement, Minnesota has long been the

seat of a considerable traffic with the Indians, and of missionary enterprise. As early as 1680 Hennepin and La Salle penetrated these wilds, followed by La Hontan and Le Sueur, and in the last century by Carver; and within the present century this region has been thoroughly explored by Pike, Long, Keating, Nicollet, Schoolcraft, Owen, and others. But it was not before 1812 that the United States had any authority within the limits of Minnesota. In 1816 a law was passed excluding foreigners from the Indian trade; and the military post of Fort Snelling was established in 1819. In 1887 a small tract of country between the St. Croix and Mississippi was ceded by the Indians to the United States, and lumbering operations commenced upon the St. Croix. The territory of Minnesota was established by an act of congress passed March 3, 1849, and the government was organized in June. It embraced nearly twice the area of the present state, its western limits extending to the Missouri and White Earth rivers. Up to this period the country was occupied almost entirely by Indians; but a small civilized population of whites and half-breeds had grown up around the trading posts and mission stations, amounting in 1849 to 4,857 souls. In 1851 the Sioux ceded to the United States all their lands in the territory W. of the Mississippi to the Big Sioux river. The population increased so rapidly after this, that in 1857 application was made for admission into the Union. The act authorizing the formation of a state government passed congress Feb. 26, 1857, and the state was admitted into the Union on May 11, 1858, with the boundaries above described. That portion of the state lying on the E. side of the Mississippi originally belonged to the country termed the "Territory north-west of the Ohio," and had the ordinance of 1787 been fully complied with would have been included in the 5th state (Wisconsin) formed from that region. This section comprises an area of 22,886 square miles. The part of the country lying W. of the Mississippi, and embracing more than two thirds of its area, was originally a portion of Louisiana, and came into the possession of the United States in 1803; and before it was included in Minnesota it had been a part of the territory of Missouri, and subsequently of Iowa.

MINNESOTA, or St. Peter's, a river of Minnesota, having its source in a series of lakes between lat. 45° and 46° N., and pursuing a S. E. course for about 800 m. to its confluence with the Blue Earth; then turning N. E. it flows in that direction for about 120 m., falling into the Mississippi at Fort Snelling. Its course is principally in the valley lying between the Coteau du Grand Bois and the Coteau des Prairies. For its whole distance from Big Stone lake it has a fall of only 220 feet. It is navigable for steamers about 40 m. to a point where at low water a ledge of rocks obstructs further progress; but ordinarily small boats can ascend to Patterson's rapids, 295 m. from its mouth.

MINNOW, the common name of many small cyprinodont fishes, of the genera *fundulus* (Lacép.) and *hydrargyra* (Lacép.). In *fundulus* the upper surface of the head is flattened; fine card-like teeth upon the jaws, and short ones on the posterior part of the hyoid arch, with opposite velvet-like patches on the roof of the mouth; no teeth on palate or vomer; branchial rays 5; dorsal opposite the anal, and caudal rounded; upper surface and sides of head covered with scales. The common minnow, or "cobbler" of the young smelt fishers (*F. piscolentus*, Cuv. and Val.), is from 1 to 5 inches long; the females are of a uniform brown color; the males with lighter intervals on the sides arranged like transverse bands, the dorsal and anal with black dots, and anal slightly emarginated posteriorly, mouth protractile, and upward when closed. This abounds about the salt marshes of the northern and middle states, and is caught in large numbers in hand nets as bait for other fish, particularly smelts. The banded minnow (*F. nigrofasciatus*, Cuv. and Val.) is less common; it is 2 or 3 inches long, yellowish green above with numerous black dots, silvery white below; 10 to 14 black bars across the sides, widest in the males; found in New England. The barred minnow (*F. maculofasciatus*, Cuv. and Val.) is about 3 inches long, olive-green above, bluish gray below, with the lighter sides marked transversely with numerous bluish bands with darker minute dots; found in New England and New York.—The yellow-bellied minnow (*hydrargyra flammula*, Storer) is from 1 to 5 inches long; the female is yellowish green above, lighter on the sides and white beneath, with from 1 to 5 longitudinal interrupted black bands extending along the sides from the gill covers to near the tail, where there are 8 or more indistinct transverse bands. In this genus the head is more flattened, and the branchial rays are 6. It is found in southern New England and New York.—The cyprinoid black-nosed dace (*argyros atronotus*, Heck.) is sometimes called black minnow. The British minnow or minim (*leuciscus phoxinus*, Cuv.) rarely exceeds 3 inches in length; it is generally found in the same streams with trout, swimming in shoals.

MINORCA, or MENORCA (anc. *Balearis Minor*), the second in size of the Balearic islands, lying 24 m. E. N. E. from Majorca, and at 130 m. S. E. from Barcelona, between lat. 39° 47' and 40° 21' N., and long. 3° 50' and 4° 20' E.; greatest length 88 m., greatest breadth 15 m., area, about 800 sq. m.; pop. about 44,000. The coast is indented on every side with small bays, several of which form excellent harbours. The surface is rugged, and rises gradually toward the centre, where it attains, in Monte Toro, an elevation of nearly 5,000 feet. The climate is very hot in summer and cold in winter, and the soil is rather sterile. Iron, lead, copper, and marble are found. The inhabitants are almost entirely engaged in agriculture, fishing, and commerce. Minorca is of great commercial

importance in the Mediterranean trade, and the capital, Port Mahon, possesses an excellent harbor. (See BALEARIC ISLANDS.)

MINORITES. See FRANCOISANA.

MINOS, in Greek mythology and legends, a Cretan hero and lawgiver. According to Homer he was the son of Jupiter by Europa, brother of Rhadamanthus, and father of Deucalion and Ariadne. The logographers make him also the brother of Sarpedon and husband of Pasiphaë. Some later writers distinguish two kings of the name, but only one Minos was known to Homer, Hesiod, or the poets and historians to the time of Aristotle. To obtain possession of the throne of Crete, he affirmed that the gods granted to him every thing for which he prayed. He accordingly prayed that a bull might come forth from the sea, and promised to sacrifice it to Neptune. The bull appeared, and he obtained the kingdom; but, admiring the beauty of the animal, he sacrificed another in its place. Thereupon Neptune afflicted his wife Pasiphaë with a monstrous passion for the bull, for the gratification of which the inventor Dædalus contrived means, and she became the mother of the Minotaur, a creature with the body of a man and the head of a bull, which was imprisoned by Minos in the Cnossian labyrinth. Minos acquired great maritime power, conquered the Ægean islands, made war upon Athens, and compelled the Athenians to send to Crete periodically a tribute of 7 youths and 7 maidens to be devoured by the Minotaur. Theseus with the aid of Ariadne at length slew the monster and abolished the tribute. In a subsequent attempt to conquer Sicily Minos failed and perished. After his death he was constituted judge in Hades to settle their disputes, but without authority to determine the reward or punishment for the previous lives of the dead. The Cretans ascribed to him their political and legal institutions.

MINOT, GEORGE RICHARDS, an American historian and jurist, born in Boston, Dec. 28, 1758, died Jan. 2, 1802. He was graduated at Harvard college in 1778, and subsequently practised law in Boston. He was successively clerk of the Massachusetts house of representatives, secretary of the convention which ratified the federal constitution, judge of probate for the county of Suffolk, and judge of the municipal court of Boston, which last office he filled at the time of his death. His publications consist of an oration on the Boston massacre, delivered in 1782; a "History of Shays's Rebellion" (8vo., 1788); "Eulogy on Washington" (1800); and a "History of Massachusetts Bay" from 1748 to 1765, with an introductory sketch of the period from the settlement of the country. Of the last named work, which is a continuation of that of Gov. Hutchinson, the 2d volume was published after his death.

MINOTAUR. See MINOS.

MINOT'S LEDGE. See LIGHTHOUSE.

MINSK, a S. W. government of European Russia, bounded N. by Vitebsk, from which it is separated by the Dûna, E. by Mohilev and

Tochernigov, S. by Kiev and Volhynia, and W. by Grodno and Wilna; area, 84,380 sq. m.; pop. in 1856, 988,188. The territory of Minsk is a vast plain, over which are scattered a few hills of moderate elevation. In the N. and E. there are large forests, and toward the S. and S. W. extensive marshes. The principal rivers are the Dnieper (which partly bounds it on the E.), Niemen, Pripetz, and Beresina. The climate is very severe in winter, but pleasant in summer. The soil is dry in the N. and to some extent fertile; in the S. mostly wet and marshy. Agriculture is the principal occupation. Minsk is divided into 10 circles, and was formerly a part of the Lithuanian provinces of Poland.—MINSK, the capital, is situated on the Swisloetz, about 150 m. S. E. from Wilna; pop. 25,000, a large part of whom are Jews. It is the seat of a Greek prelate and a Roman Catholic bishop. The nuns of Minsk were subjected to persecution by the emperor Nicholas in 1840.

MINSTREL, one of a class of men in the middle ages, who gained a livelihood by the arts of poetry and music, singing to the harp their own verses, or the popular ballads and metrical histories of the time. They sometimes accompanied their music with mimicry and action, so that they were often called *mimi* and *histriones*. The term minstrel is of Norman origin, and was introduced into England with the Norman conquest. Edward II., Henry V., and Henry VI. showed great regard for minstrels; but the reign of Richard Cœur de Lion was their golden age. When Henry V. set out on his great expedition to France, 18 minstrels, with an allowance of 12*d.* a day each, accompanied him. But from the reign of Edward IV. their art seems to have declined. Toward the close of Elizabeth's reign a statute was enacted, by which wandering minstrels were punished along with rogues, tinkers, peddlers, vagabonds, and beggars.

MINT (*mentha*, from Mintha, a nymph changed into this plant), commonly understood to signify, in botany, what we call spear mint or common mint (*M. viridis*, Linn.). It is a native of Europe, though found about moist ground and waste places in the United States, having strayed from gardens and fields where it has been cultivated. In appearance it is handsome, cleanly, of a deep green color, with an erect stem 1 to 2 feet high, furnished with oblong-lanceolate, subsessile, acutely cut, serrate leaves, and ending in slender, tapering spikes of pale, purple-corolled flowers. The fresh leaves when bruised are employed as a sauce, and in the preparation of a beverage known as mint julep. There are several species of *mentha* to which is affixed some descriptive title, and which are in this sense mints, such as the peppermint (*M. piperita*, Linn.), likewise naturalized in many places in America, though indigenous to Europe; also others not commonly seen among us, but known abroad, such as the *M. rotundifolia*, *aquatica*, and *pulegium*, having similar properties as stimulating medicines; but peppermint is by far the most pleas-

ant, and is chiefly used to relieve nausea or to cover the unpleasant taste of other medicines. This mint is largely cultivated, especially in the state of New York, for the manufacture of the oil of peppermint, of which great quantities are consumed by confectioners in flavoring candies, lozenges, &c., and by druggists and liquor dealers in preparing essences, cordials, and the like. Essence of peppermint is a solution of the oil in alcohol, of different degrees of strength. Another species possessing the singular odor of decaying cheese is known as the corn mint (*M. arvensis*), having, unlike the others, hairy stems, petioled ovate or oblong leaves, and globose, remote whorls of flowers. This is likewise considered an adventitious plant from Europe, and is rarely met with, occurring in fields in Pennsylvania and Ohio. The wild mint (*M. Canadensis*, Linn.) is not uncommon in wet grounds by the sides of brooks to the northward, and extending from New England to Kentucky. It has whitish, hairy, square stems, rising upward from 1 to 2 feet high; its leaves are oblong, tapering at both ends, supported on footstalks; its flowers in regular axillary whorls, and having pale purple corola. In taste and properties the species is similar to pennyroyal. It is considered identical with the *M. borealis* of Michaux.—The mints are readily raised by planting out the running rootstocks in rich but moist ground. They belong to the natural family of *labiata*. Several species of *pycnanthemum* common to the United States are called horse mints; they are handsome herbs, with perennial roots, soft downy foliage, and rather small, whitish blossoms, all having pungent, aromatic, and mint-like flavors, and growing generally in dry soils or on rocky places.

MINT (Sax. *mynet*, money), a place where money is coined. To make the money of a country, and declare the same a legal tender in the payment of debts, is necessarily a prerogative of its government. Nothing short of the public faith can afford a sufficient guaranty of the integrity of the standard by which all values are to be measured. Each country has to provide therefore for a national currency; and this is usually done through the agency of a national mint. In early Saxon and Norman times, almost every important town in England could boast a mint; but as the commerce of the country became systematized and the modes of communication improved, these local mints became unnecessary. From the time of William the Conqueror until 1811 the great bulk of the coinage was done in the tower of London; and since that time the royal mint on Tower hill has been found adequate for the coinage of the entire kingdom. In France, previous to 1772, there were 81 mints; at that date the number was reduced to 18. At present, although mints still exist at Paris, Bordeaux, Lille, Lyons, Rouen, and Strasbourg, the coinage is almost wholly done at Paris; the tendency being as in England to concentrate the coinage operations of the country in its commercial metro-

polis.—The early methods of coining money were exceedingly imperfect. The metal, having been brought to the required standard of fineness, was melted and cast into small bars, which were reduced to thin plates under the hammer. Square pieces cut from these plates were rounded at the forge, and then by means of rude dies—one fixed like an anvil to a block and the other held in the hand and struck with a mallet like a punch—the round lump of metal was flattened and coined at the same time. The difficulty of thus placing the two dies exactly opposite suggested occasional improvements; but it was not till about the middle of the 16th century that the forge and hammer gave place in France and England to the mill and screw, a French invention by which the bars were reduced to their proper thickness by rolling, and the pieces were coined by the pressure of a screw. In the British mint screw presses, impelled by steam, continue to be used at the present day; while in France, the United States, and some other countries, the lever presses of Thonnelier have been substituted.—The mint establishment of the United States consists of the principal mint at Philadelphia and 5 branches, located respectively at New Orleans, La.; Charlotte, N. C.; Dahlonega, Ga.; San Francisco, Cal.; and New York city, the last named being styled an assay office. The mint was established by act of congress of April 2, 1792, at Philadelphia, which was then both the seat of government and the commercial metropolis of the country. It was not fairly in operation until Jan. 1795. The branch mints at New Orleans, Charlotte, and Dahlonega were established by the act of March 3, 1835, and commenced operations in 1838, the one at New Orleans being for the coinage of gold and silver, and the other two for gold only. The branch mint at San Francisco, for the coinage of gold and silver, was established by act of March 3, 1852, and went into operation in 1854. The U. S. assay office at New York, established by act of congress of March 4, 1853, also commenced operations in 1854. The functions of the assay office are the same as those of the branch mints with the single exception of coining. Gold and silver bullion is received as deposit, weighed, melted, assayed, and refined on precisely the same terms as at the Philadelphia mint, and returns are made either in coined or stamped bars at the option of the depositor. That portion of the bullion, however, which is paid for in coins, or an equivalent amount, must necessarily be sent to the mint at Philadelphia, to be coined and returned. These branch establishments are managed by superintendents appointed by the president of the United States, and the general direction of the business of the branches is under the control and regulation of the director of the mint at Philadelphia, subject to the approbation of the secretary of the treasury. The whole establishment, thus constituted, is itself a bureau of the treasury department, and its operations

are annually reported to congress through the secretary of the treasury, and made public.—The course of business at the mint and branches is briefly as follows. Deposits of bullion, not less than \$100 in value, are receivable by the treasurer, who weighs the same in the presence of the depositor, and gives him a receipt therefor expressing the weight in troy ounces. Each deposit is kept separate during the process of melting and assaying, and until its precise value is determined. This is ordinarily accomplished in 2 or 3 days, when, on presentation of the original receipt, the net proceeds are paid to the depositor or his order. At the time of payment, the treasurer furnishes the depositor a "memorandum" exhibiting the weight of his bullion before melting and after melting, its fineness and value, the amount of silver contained if a gold deposit, and *vice versa*, the "deductions" for parting, coinage, or bars, and the net amount payable. The charges made to depositors are for parting when gold and silver are combined, for refining and toughening when required, for coinage or fine bars according as a deposit is paid in one or the other. The law provides that these charges shall be fixed from time to time by the director with the concurrence of the secretary of the treasury, so as not to exceed the expense to the mint of the labor and materials employed. The existing charges for parting on gold bullion of the ordinary range of fineness, at Philadelphia, New York, and New Orleans, is 5 cents per oz. gross; at Charlotte and Dahlonega, 12 cts.; and at San Francisco, 14 cts. The coinage charge at all the mints is 50 cts. per \$100, and for fine gold bars 6 cts. per \$100. The charges for refining and toughening depend upon the condition of the metal deposited.—The organization of the several mint establishments is essentially the same. The officers are a director (or superintendent), a treasurer, an assayer, a melter and refiner, a coiner, and at the principal mint only an engraver. To these officers, as well as the clerks and workmen, are paid salaries or wages regulated by law, for which annual appropriations are made by congress. A portion of the incidental expenses are covered by the charges on deposits; but no commissions or perquisites of any kind are enjoyed by any one belonging to the establishment. The expenditures of the mint establishment for the fiscal year ending June 30, 1859, were \$766,152.11.—The various processes employed in the mint, particularly in the coinage department, cannot be minutely described without the use of diagrams. An attempt will be made, however, to give the reader a general understanding of the subject. Each deposit of gold or silver, when received by the treasurer as already described, is properly numbered and sent to the deposit-melting room to be melted and cast into one or more bars. The object of this melting is to bring the metal into a homogeneous state, so that an assay piece taken from it shall fairly represent the mass. This being done,

the deposit remains in the custody of the treasurer. The assayer, operating upon a small but definite quantity by weight of the assay piece which he has taken, determines, by an exceedingly delicate chemical analysis, the proportion of gold or silver or both which it contains, and reports the result to the treasurer. The fineness thus reported, and the weight of the deposit after melting, are the data for calculating its value and adjusting the claim of the depositor. Deliveries of bullion, composed of these various deposits, are made from time to time by the treasurer to the melter and refiner, and are charged to him in account. It is his province to subject them to the necessary processes for refining them, and to convert them into ingots of standard metal, 900 thousandths fine, suitable for the fabrication of coins. The method of refining or parting in use in the mints of the United States is the nitric acid process, and consists in the dissolving of the silver contained in gold by nitric acid, and its subsequent precipitation by a solution of common salt. The chloride of silver thus obtained is reduced to fine silver by the action of sulphuric acid and granulated zinc. Both the gold and silver, when recovered from the parting process, are in the form of a fine powder, and in appearance wholly unlike those metals as ordinarily seen. They only require to be melted, however, to show what they are. From the fine gold and silver thus obtained, by the addition of the requisite amount of copper for alloy, the melter and refiner makes up pots of standard metal, and casts the same into ingot moulds of the sizes required for the coins which are to be made. When these ingots have been assayed by the assayer and certified by him to be of standard fineness, they are delivered by the melter and refiner to the treasurer, by whom they are credited in account. The account of the melter and refiner is settled annually by his returning to the treasurer all the metal in his possession, and he is entitled by law to an allowance for necessary wastage, provided it shall not exceed $\frac{1}{100}$ of the whole amount operated upon during the year. This limit is very seldom reached. We have not the means of giving the wastage of the mint or branches. At the assay office at New York, from the commencement of operations in Oct. 1854, to Dec. 31, 1859, the melter and refiner's wastage on gold was less than $\frac{1}{100}$ part of the legal allowance, and on silver $\frac{1}{100}$ part. The amount in value by which his actual wastage fell short of the legal limit during this period of 5 years was \$191,151.55. A statement of the experience of the mint would doubtless show results equally favorable. The ingots of standard metal delivered by the melter and refiner to the treasurer, as above described, are next delivered to the coiner. An ingot is a flat bar of metal about 12 inches long, $\frac{1}{2}$ of an inch thick, and from $\frac{1}{2}$ to $1\frac{1}{2}$ inch wide. By means of powerful but accurately constructed rollers, driven by steam, the ingots are rolled out into thin strips or ribbons of the proper thickness for the coin designed to be made. In

the process of rolling, the strips require to be occasionally annealed in furnaces constructed for that purpose. After the final rolling, the strips are taken to a drawing bench, in which they are drawn, like wire, through a steel gauge to make them straight and of uniform thickness. Next comes the cutting press—a vertical steel punch working accurately into a matrix or round hole in a steel plate of the size of the planchet required, and operated rapidly by an eccentric—under which the strips are fed by hand, and the disks or planchets falling through the hole in the plate are caught in a box below. The gold planchets are subjected before coining to a careful adjustment by weight. This is done by females, whose delicacy of touch fits them admirably for this service. Seated at a long table, each one has a balance before her and a flat file in her hand; and the gold planchets are successively tried against a counter weight. Those that are too light are thrown aside to be remelted, and those that are too heavy are brought to the proper weight by moving the file lightly round the edge. The planchets thus adjusted are now ready for the milling machine, an exceedingly simple but beautiful piece of mechanism of American invention, by which the planchets, as rapidly as they can be fed by hand into a vertical tube, are caught one by one edgewise, and caused to rotate in a horizontal plane in a channel formed on one side by a revolving wheel, and on the other by a fixed segment of corresponding curve, but slightly nearer the wheel at one end than at the other. The effect is that each piece in passing through this narrowing channel has its edge evenly crowded up into a border or rim. After being annealed and cleaned or “whitened,” the planchets are ready for the coining press. The coining press in use in all the mints of the United States, as already mentioned, is constructed after the plan of the French lever press invented by Thonnelier. Without drawings a minute description of this beautiful machine would be impossible. Suffice it to say that the pressure upon the die, formerly accomplished by the screw, is in this machine effected by a lever moved by a crank and operating a strong toggle joint. The planchets being fed by hand into a tube or hopper in front of the machine, the lower piece in the tube is seized by steel feeders and carried forward and lodged in the collar between the upper and lower dies. At the same moment the lever is descending, and by the time the planchet is in position the toggle joint, brought into a vertical position, imparts to the piece a pressure which within the narrow limits of its motion is almost incalculable. The immediate relaxation of the joint causes the upper die to be lifted, when the feeders, coming up with a second planchet, push away the one already coined, and cause it to slide over a sloping channel into a box below. The planchet before being struck is slightly less in diameter than the steel ring or collar into which it drops; but the pressure upon the dies is such as to cause the piece to expand into

the collar and take from it the reeding or fluting of its edge. The coins, after being carefully inspected by the coiner to eliminate defective pieces, are counted and put up in bags, and delivered to the treasurer, by whom the coiner is held to the same accountability as the melter and refiner. The counting is performed with great accuracy and despatch by a counting board of very ingenious construction, invented by the late Rufus Tyler, coiner of the New Orleans branch mint, and purchased by government for the use of the mints. The dies used in all the mints of the United States are made under the supervision of the engraver of the principal mint. The production of original dies cut by the engraver's hand in steel is a work of great labor, and it would be impossible in this manner to supply the dies necessary for the coinage of the country. A very ingenious process is employed for multiplying them. The original dies, being carefully finished and hardened, are used simply to strike copies in softened steel, which is done by repeated blows under a powerful screw press. As the devices upon the original dies were sunk, these copies will be in relief. To prepare dies for coinage, therefore, this hardening and copying process must be repeated. The durability of the dies used in coining depends mainly on the skill with which the softening and hardening have been accomplished. A rigid system of registration and accountability is necessary to keep the old dies from falling into improper hands.—In the various operations of the mint, particularly in those of the melter and refiner's department, a large amount of precious metals will be temporarily lost by becoming absorbed in the melting pots and fluxes and mixed with the ashes and *débris* of the furnaces. These materials are carefully gathered up, and the gold and silver extracted from them by various methods. This part of mint operations has been recently much simplified and cheapened by a sweep-washing machine invented by E. N. Kent, the melter and refiner of the assay office at New York, and purchased by congress for the use of the mints. Formerly the sweepings of the mints, even after a most laborious process of hand-washing, contained gold and silver of the value of from 50 cts. to \$1 per pound. At present, as issued from the assay office, their average value does not exceed 7 cts. These sweepings are sold in the market to smelters.—From a humble origin in 1792, the mint of the United States has in 68 years attained to gigantic proportions. The various and complicated enactments of congress respecting the mint and coinage were mainly superseded by the admirable mint law of Jan. 18, 1837, drawn up by the late director Dr. Robert M. Patterson, under whose direction also most of the existing improvements in machinery were introduced, and the capacity of the mints developed from a coinage of \$5,000,000 to \$68,000,000 per annum. The directors of the mint since its organization have been as follows: 1, David

Rittenhouse of Pennsylvania, July, 1792, to July, 1795, previously treasurer of Pennsylvania; 2, Henry Wm. De Saussure of Charleston, S. C., July 11 to Oct. 28, 1795, afterward chancellor of South Carolina; 3, Elias Boudinot of New Jersey, Oct. 1795, to July, 1805, previously president of congress under the confederation; 4, Robert Patterson of Philadelphia, July, 1805, to July, 1824, vice provost of the university of Pennsylvania, and president of the American philosophical society; 5, Dr. Samuel Moore of Pennsylvania, July, 1824, to July, 1835, member of congress from Bucks co., Penn.; 6, Dr. Robert M. Patterson of Philadelphia, July, 1835, to July, 1851, professor of mathematics in the university of Pennsylvania, of natural philosophy in the university of Virginia, and president of the American philosophical society; 7, Dr. George N. Eckert of Pennsylvania, July, 1851, to April, 1858, member of congress from Lebanon co., Penn.; 8, Thomas M. Pettit of Philadelphia, April to June, 1858, judge of the district court of Philadelphia; 9, James Ross Snowden of Pennsylvania, June 1858 (present incumbent), previously speaker of the house of representatives of Pennsylvania, treasurer of Pennsylvania, and treasurer of the mint. (For some notice of colonial mints, see COINS.)

MINUCIUS FELIX, MARCUS, a Latin Christian writer, belonging, according to St. Jerome, to the first half of the 3d century. He was a native of Africa, but removing to Rome, became distinguished as an advocate before his conversion to Christianity. He is now only remembered as the author of an apology for Christianity, entitled *Octavius*, in which Octavius, a Christian convert, and Cæcilius, a pagan, discuss the relative merits of their respective religions. In this dialogue, Minucius defends the Christians from the calumnies then in circulation against them, while he exposes the licentious practices of the pagans, giving much information concerning the manners and customs of the times. It is, says Neander, "a felicitous and dramatic representation seized from the life, replete with good sense, and pervaded by a lively Christian feeling." It was at one time supposed that *Octavius* formed part of Arnobius's treatise *Adversus Gentes*; but Baldwin, in 1560, corrected the mistake. Editions of the dialogue were published at Leyden in 1709, and at Cambridge, Eng., in 1712; and it has been translated into French and German, and into English in Reeves's "Apologies of Justin Martyr," &c., vol. ii. A work called *De Fato*, now lost, was also ascribed to Minucius, probably without cause.

MINUET (Fr. *menuet*), a dance of a graceful and stately character, which had a celebrity in the last century equal to that at present enjoyed by the quadrille, the waltz, the polka, and other popular modern forms of dancing, but which is now rarely practised except on the stage. It is supposed to have originated in the French province of Poitou, and to have made its ap-

pearance in the latter half of the 17th century. The name has been derived from *menu*, "little," the steps of the dance being short. The time regulating the movements of the minuet consists of 2 strains or parts, of 8 bars each, in 3-crotchet time, both of which from being repeated are called *reprises*.—The minuet or *minuetto* has also been effectively employed by composers as an exclusively musical movement in symphonies, quartets, &c. In this use the 2 strains consist of 16 bars each, and after being repeated are succeeded by a trio, after which the minuet is again played through somewhat more quickly. The time of this movement, which is of German origin, is an *allegro*, and in the second performance of the minuet it is accelerated to *presto*.

MINUTE (Lat. *minutum*), the space of time equal to the 60th part of an hour; also used to denote a portion of the arc of a circle, and as a measure of angles. When the circumference of the circle is divided into 24 hours, the minute is $\frac{1}{24}$ part of the circle. When the circle is divided into 360°, the minute is the 60th part of a degree, consequently equal to $\frac{1}{60}$ of the circumference. To distinguish these two measures, the former is called a minute of time, the latter a minute of arc; 15 minutes of arc being equal to one minute of time, and 4 minutes of time to a degree.

MINUTOLI, HEINRICH MENU VON, baron, a German traveller and archæologist of Italian descent, born in Geneva, May 12, 1772, died near Lausanne, Sept. 16, 1846. He entered the Prussian army at an early age, was wounded during the campaign on the Rhine in 1798, and made tutor of Prince Charles and major-general. In 1820 he led a scientific expedition to Egypt under the patronage of the Prussian government. He intended to visit the ruins of Cyrene, but the faithlessness of his Arab guides compelled him to relinquish this project and to confine his journey to Cairo, Thebes, and Asswan, whence he returned to Alexandria, reaching Berlin in Aug. 1822. The architect Liman, the naturalist Hemprich, and 7 of his other companions had died on the journey, and a great portion of his collection was lost by shipwreck. The remaining part of it was purchased by the king of Prussia. Minutoli published a narrative of his travels under the title of *Reise zum Tempel des Jupiter Ammon und nach Ober-Aegypten*, and wrote various historical and archæological works and essays on a great variety of subjects.—His wife, WOLFERDINE, who still lives in Berlin, accompanied him to Africa, and wrote in French *Souvenirs d'Égypte* (Paris, 1826; German translation, Leipsic, 1829).—JULIUS VON, son of the preceding, born in Berlin in 1805, has officiated since 1851 as Prussian consul-general for Spain and Portugal in Madrid, and has published, beside other works, *Spanien und seine fortschreitende Entwicklung* (Berlin, 1852).

MIOCENE, one of the groups into which the tertiary formation is divided by Lyell, intermediate between the eocene below and the pliocene

above—an arrangement founded on the proportional number of fossil shells these divisions severally contain. The name is derived from the Gr. *μειον*, less, and *καινος*, recent, and is intended to express a minor proportion of recent species. The strata of which it consists are chiefly beds of clay and marls more or less made up of organic remains, and sands sometimes consolidated into sandstones. For the nature of the fossil remains and the distribution of the formation, see *GEOLOGY*, vol. viii. p. 160.

MIRABEAU, GABRIEL HONORÉ DE RIQUETTI, comte de, a French political orator and publicist, born on his father's estate of Bignon, near Sens, March 9, 1749, died in Paris, April 2, 1791. A huge-headed infant who had come into the world with a pair of grinders, one foot twisted, and tongue-tied, disfigured when 8 years old by confluent small pox, he grew up "as ugly as the nephew of Satan," giving such signs of bodily strength, passionate temper, power of mind, and impetuosity, as to be styled by his father "a monster physically and intellectually." He was, however, quite accessible to reason and kindness; but his father, who called himself the "friend of men," and was in fact a domestic tyrant, made up his mind to break down the ungovernable "monster" by severity, contempt, and punishment. Encouraged to this by a Swiss woman, Mme. de Pailly, who had usurped in his household the place of the absent lawful wife, he was for many years the persecutor of his own son, who must have been gifted with much natural goodness and magnanimity to go through such trials without becoming a confirmed reprobate. After having him educated at home by private tutors, who, in his eyes, were entirely too indulgent for such a "dishevelled bully," the marquis placed him at a military school in Paris, depriving him of his rightful name, and contemptuously calling him "M. Pierre Buffière." On July 19, 1767, he entered him as a volunteer in the Berry regiment of cavalry, under a colonel notorious for his severity; but "Pierre Buffière" behaved so well as to give full satisfaction to his superiors. Being left penniless through his father's meanness, he contracted a few debts, lost 40 louis at the gaming table, and surpassed his colonel in the affections of a young girl at Saintes. These offences brought upon him the wrath of his father; and he was lodged for several months in the fortress on the isle of Ré. Here he made a friend of his gaoler, who reported favorably concerning him. In consequence of this, his father, instead of sending him to die by fever in Surinam, as he at first intended, procured for him a commission as 2d lieutenant in the regiment of Lorraine, which was sent to Corsica in 1769. During a year of hard service, he evinced such alacrity, courage, and fidelity, as to command the esteem of his officers and the affections of his comrades. On his return he was sent to his uncle, the bailli of Mirabeau, in Provence, and soon, by his frankness, cordiality, and cheerfulness, concil-

iated the old man, who undertook to bring the father to a better feeling toward the discarded son. The latter on his part spared no effort to placate his sire, working "like a galley slave" to improve the ancestral estate of Mirabeau and better the condition of the neighboring peasants. He was at last allowed to assume his right title, and moreover to visit Paris in the spring of 1771. He was now presented at the court, and for a while brilliantly kept his rank among the young nobles. The time arrived for him to marry; by his father's advice, he paid his addresses to an heiress in Provence, Marie Émilie de Covert, the only daughter of the marquis of Marignane, and, in spite of rivals and obstacles, conquered the young lady, who, on June 22, 1772, became his wife. This was the starting point of new and greater misfortune. On account of the inadequate income that had been assigned to him, Mirabeau, who had a taste for magnificent living, soon became involved in pecuniary difficulties. His father not only declined to help him, but prevented the marquis of Marignane from lending him the means of relief. He moreover got a *lettre de cachet* against the "spendthrift," who was ordered to retire to Manosque, and who here, while his wife bore him a son, wrote an essay upon despotism. But Mirabeau, having dared to absent himself for a few hours from the village, in order to rescue a friend from a matrimonial difficulty and avenge an insult that had been offered to his younger sister, was, by his father's order, Aug. 28, 1774, caged in the gloomy castle of If at Marseilles; and while his wife and family prayed for his release, the iron-willed marquis had the prisoner removed, May 25, 1775, to the fort of Joux, in the Jura mountains. Being allowed occasionally to visit the neighboring town of Pontarlier, he fell in love with Sophie, marchioness de Monnier, the young and gifted wife of an old magistrate whom 4 years before she had reluctantly wedded. His love was reciprocated; but, conscious of the dangers of this attachment, Mirabeau tried to avoid them by calling his wife to him, as a safeguard against his own passion; the marchioness sneeringly declined the summons, and the two lovers were left to themselves. Both were subjected to persecution, he from the commander of the fort of Joux, she from a jealous husband. He finally fled alone, and wandered for many weeks in Switzerland and the S. E. part of France, yielding occasionally to the attraction that brought him back to the vicinity of the town where his mistress was suffering every kind of severity. "Gabriel or death," she cried; and on the night of Aug. 23, 1776, dressed in man's attire, she escaped from her husband's home, scaling the garden wall by a ladder, and flew to Verrière, Switzerland, where her lover had just arrived. A few weeks later they were in Amsterdam, where Mirabeau, under the fictitious name of St. Mathieu, tried to make a living by writing for Dutch publishers. He succeeded, made some transient

from the English, and wrote his *Avis aux Hessois*, an eloquent pamphlet against the Hessian sale of soldiers to England for putting down the American revolution. Amid this busy life, May 14, 1777, both himself and his companion were arrested by a French police officer, sent by his father and her husband. Four days before he had been sentenced by the tribunal of Pontarlier to be beheaded for "forcible abduction and seduction," while she was condemned to imprisonment for life. For the present they were carried off to Paris, Sophie to a private penitentiary, which she was soon to exchange for a convent at Gien, and Mirabeau to the dungeon of Vincennes, where 42 months of close confinement awaited him. His father had resolved upon keeping him a prisoner for life, but eventually changed his mind. This was a period of frightful bodily and mental trials for Mirabeau; once he was about giving himself up to despair, and by the middle of 1778 he had made every preparation to take his own life. But hope and courage returned; and he went on, incessantly engaged in writing love letters to the unhappy Sophie (a favor which had been kindly granted to him by the chief of police, Lenoir, as the only means of preventing his suicide), deprecatory letters to his father, uncle, sister, and friends, and above all literary works through which he was able to earn some money to relieve his own and Sophie's wants. In fact he was little more than a pauper, his father not even allowing him enough to procure decent clothing. His incarceration, interrupted by a single hour a day for walk and exercise, brought on gravel, stone, bloodspitting, and, what was still more cruel to a man whose only consolation was found in his books and correspondence, failing eyesight. He withstood all, and battled manfully against misery. Among the works which he wrote during his stay at Vincennes, the most important was his *Lettres de cachet et prisons d'état*, remarkable alike for eloquence and learning. His entreaties to his father, which passed almost unnoticed, would have been useless, if the latter, moved by the death of his grandson, Victor, had not thought of the necessity of "perpetuating the family," which made him "swerve from the word he had given to keep the father in prison." It was however 26 months only after the death of the child, Dec. 13, 1780, that Mirabeau saw the door of his dungeon open. His first work on regaining his liberty was an attempt to settle the warfare that had been going on between his parents for many years; but here he failed. His mother was for ever alienated from him; but the success which she obtained in her lawsuit against her husband, was followed at once by the reconciliation between father and son, May 20, 1781. For several months the latter had devoted himself to winning his father's affections, and in this he was partly successful. During this period he had an interview with Sophie. Jealousy and suspicion had previously existed between them; now came reproaches and recrimina-

tions. "The anger on both sides passed all reasonable bounds;" and so the lovers parted for ever. He however did not separate his cause from hers when, in 1782, he went to Pontarlier in order to have the sentence of May 10, 1777, reversed. He had already effected much toward this desired end, when a compromise, effected by his brother-in-law, Count du Saillant, put an end to a difficult litigation. While Mirabeau had, as he said himself, "his head replaced upon his shoulders," Sophie was separated from her husband, receiving back her dowry and an annuity of 1,200 livres beside. Mirabeau has been charged with having, by his dereliction, caused her death; this is entirely erroneous. Sophie, who seems to have forgotten Mirabeau previous even to his liberation, had, after the death of her husband, recovered her entire freedom, and engaged to marry a gentleman of the name of Poterat. He having died of consumption, she put an end to her own life, Sept. 9, 1789. Another and still more difficult task was now before him—a reconciliation with his wife. For nearly 8 years she had been separated from him; and although she had no hatred against him, she was wholly under her father's control, who entertained the most decided hostility to his son-in-law. Mirabeau went to Provence, and on his arrival wrote the most humble and touching letters; but they were at first answered coldly, then with insults, and finally sent back unopened. He then resorted to law proceedings, which he conducted himself with marked ability and a moderation which was scarcely in accordance with his known temper. Here it was that he, for the first time, evinced the powerful eloquence that was to shine so brilliantly in the constituent assembly. His pleadings before the parliament of Aix created deep emotion among the people of that city, the majority of whom sided with him; but one half of the judges were relatives of Marignane, and the court decreed, July 5, 1783, that the wife should remain separated from her husband. Mirabeau was defeated, but he had made himself so popular that he was "the idol of the whole country." He was determined to appeal, but was baffled by the difficulties he met in his own family and at the hands of the keeper of the seals. Having published in Belgium a new case in which the latter was unsparingly handled, he thought it prudent to absent himself from France, and went to England, where he saw the best society and published his *Considérations sur l'ordre de Cincinnatus*, and his *Doutes sur la navigation de l'Escaut*, a defence of the Dutch monopoly against the designs of the emperor Joseph II. He returned to Paris in April, 1785, and wrote several able pamphlets on financial matters. At the close of this year he visited Berlin, where Frederic the Great twice gave him a private audience. Here he published a pamphlet upon Cagliostro and Lavater, and an "Essay on Moses Mendelssohn

and the Jews." After paying a short visit to Paris, he returned with a secret mission from the French ministry. For 6 months he held a semi-official correspondence, and accumulated materials for a great work upon the Prussian monarchy. In 1787 he returned to France, and tried in vain to be appointed clerk of the assembly of notables; wrote a pamphlet, *Dénonciation de l'agiotage*, in which he commenced his assaults upon Necker's financial policy; and, being threatened with another *lettre de cachet*, went to Brunswick, where he completed his work, *De la monarchie Prussienne*, which was published the next year (8 vols. 8vo. and 4 vols. 4to.). With the exception of the few months of his mission to Prussia, he had recently been greatly embarrassed by pecuniary difficulties; but now he found himself in the most wretched situation; and it was probably under the pressure of sheer penury that he published, under the title of *Histoire secrète du cabinet de Berlin*, his confidential letters to the French ministry. This publication was ordered to be burned by the hands of the executioner. The convocation of the states-general being now announced, a new field opened to the feverish activity of Mirabeau. He went to Provence in the beginning of 1789, and presented himself for election to the nobility of this province; but he soon drew upon himself their implacable hostility by his boldness in the discussions as to the mode of election. He was finally expelled from their assembly, as having no fief of his own, and threw himself into the arms of the third estate. Here he was enthusiastically welcomed; his reception at Marseilles and at Aix was triumphant, and his influence was so powerful over the popular classes, that he was called by the authorities to quell serious disturbances which had broken out in those cities. His exhortations were respectfully heeded by all; and for a while he was literally the sovereign of Provence. He was elected in both the cities he had protected against disorder and pillage, and finally decided to sit for Aix. He now returned to Paris. On his appearance at Versailles, on May 4, 1789, in the procession among the deputies of the third estate, he was eagerly observed by all, being hissed by some and applauded by the majority of the crowd. In the assembly, where strong prejudices against him had been created by the recklessness and follies of his past life, he had to struggle hard to gain an influential position, and indeed he never succeeded in it entirely; he never had any party there; nevertheless, through his genius, his commanding superiority in reasoning, that blending of logic and impetuosity which was so characteristic of his eloquence, he swayed it at will on almost every important occasion. He was the mouthpiece of the revolution, and hence his power. He encouraged the third estate to maintain their rights against the pretensions of the other orders. At the end of the royal sitting of June 28, he sent the grand

master of ceremonies back to the king with this bold answer: "Go and tell your master we sit here by the will of the people, and that we are only to be driven out by the bayonet." But he was not hostile to the royal power; from the beginning he was ready to uphold any plan that, while strengthening royalty, would have secured liberty to the people. He did not favor mobs and riots, being anxious to achieve reforms through the instrumentality of the lawfully constituted assembly; and when he saw that the revolutionary tide was carrying the monarchy toward the abyss, he was willing to ally himself with the king in order to prevent that consummation. He had already advocated with unflinching energy the royal prerogative in the veto question. He now consented to act more directly in behalf of a policy which was the only safe one; and, while "utterly opposed to a counter-revolution," he declared himself ready to make an effort for "the restoration of the king's legitimate authority as the only means of saving France." In consequence of this determination, part of his debts about 80,000 francs, were paid by order of the king, and he received a monthly pension of 6,000 francs to help him in the furtherance of his designs. He also received 4 notes of 250,000 francs each; but these were given back to the king on the great orator's death. This has been seized upon by his enemies as evidence of his venality. It must, however, be observed that, although paid by the king, he was but following up his own system; he certainly would not have sold his own convictions; he never did this even during the worst hardships of his precarious life. While these arrangements were going on, Mirabeau engaged in one of his most celebrated oratorical contests. On May 20, in an elaborate oration, he supported the king's right to declare peace or war. On this he struggled alone against several celebrated orators, and especially against Barnave, whose popularity was now more than equal to his own. While Barnave was borne in triumph, the very tree was marked upon which Mirabeau was to be hanged; hawkers went about selling a pamphlet in which he was charged with treason and corruption. Unterrified he faced the storm; on May 28 he proceeded to the hall amid the threatening clamors of an angry crowd, ascended the tribune, and, alluding to what was going on, said: "A few days ago, I also was to be carried in triumph, and now they are bawling through the streets: 'The great treason of the count of Mirabeau.' This lesson was not necessary to remind me that the distance is short between the capitol and the Tarpeian rock; but the man who fights for common sense and his country is not so easily conquered." He went on in a strain of fervid and convincing eloquence, and came out triumphant. He took part in nearly all the succeeding debates, making no exertions to insure the success of the cause he advocated. Repeated efforts that would have exhausted the energies of any other man

seemed but to give new impetus to his activity. "A day to him," says an eyewitness, "was more than a week or a month to others. The mass of business he carried on simultaneously was prodigious; from the conception to the execution not a moment was lost." To his absorbing duties as a deputy were added those of a journalist; from the opening of the states-general he had been publishing a journal, which, first under the title of *Journal des états généraux*, then *Lettres à mes constituants*, and finally *Courrier de Provence*, gave a report of the sittings, and freely discussed all the questions of the day. To meet the exigencies of his twofold task, beside occasional assistance he received from friends or outsiders, he had called around him coadjutors, such as Dumont, Duroveray, Reibaz, and others, who not only wrote for his periodical, but assisted him in the preparation of such documents as were needed, and even in his speeches. These men were of great service to him, and the two former especially may claim a large share in the composition of some of his best orations, though in fact they only furnished materials in compliance with his directions; his genius infused life into their productions; between a speech as written by Dumont or Duroveray, and as delivered by the commanding orator, there was as much difference as between a dead body and a living being, full of fire and enthusiasm. Mirabeau's speeches, whatever the pen that sketched or worded them, are incontrovertibly his own, as he not only suggested them, but vested them with a life and splendor which came from himself alone. It was during his later months that he uttered some of his most powerful appeals to the assembly, and, in spite of all assaults and slanders, exercised in it a controlling power. But his strength became exhausted amid his Herculean labors, rendered still more dangerous by high living and licentiousness. Nothing could persuade him to repose. On March 27, 1791, though frightfully ill, he occupied his seat in the assembly and spoke no fewer than 5 times; but this was the finishing blow to his undermined constitution. He went home nearly dead; and his friend and physician Cabanis saw at once that the end was approaching. The news of his dangerous illness spread over Paris like a public calamity; the Chaussée d'Antin, the street in which he lived, was thronged by the multitude who anxiously inquired after his condition; bulletins were printed and distributed every hour; twice a day the king sent a messenger to his house for tidings. On the eve of his death, he heard the sound of distant guns. "Have we already," he said, "the funeral of Achilles?" After a night of terrific suffering, at the dawn of day he addressed his physician Cabanis: "My friend, I shall die to-day. When one has come to such a juncture, there remains only one thing to be done; that is, to be perfumed, crowned with flowers, and surrounded with music, in order to enter sweetly into that slumber from which there is no awak-

ing." He ordered his bed to be brought near the window, and looked with rapture at the brightness of the sun and the freshness of his garden. For three quarters of an hour he freely conversed with La Marck and Cabanis. "I carry away with me," he said, "the mourning for the monarchy; its shreds will now be the spoil of the factions." Toward night he suffered dreadfully, and insisted that his physician should give him opium to relieve him from his tortures. Cabanis refused; but in order to pacify his anger, he pretended to consent, giving him a few drops of a harmless mixture. A few minutes later he breathed his last. He had not yet completed his 42d year. His loss was mourned by the whole nation; every one felt that the ruling spirit of the revolution had passed away. His body was carried in pomp by the assembly and the people to the church of Ste. Geneviève, which was henceforth to be called the Pantheon of France, with this inscription on its front: *Aux grands hommes la patrie reconnaissante*. Three years later, by order of the convention, Mirabeau's remains were taken to the churchyard of St. Catharine, the resting place of criminals, while those of Marat took possession of the Pantheon.—The *Œuvres de Mirabeau* have been published by Barthe (8 vols. 8vo., Paris, 1819), and by Mérimée (9 vols. 8vo., 1825-'7); but neither of these collections is complete, while the biographical notices by which they are accompanied are far from correct. Many of his productions have had but one edition, and are now difficult to find. The large biography by Peuchet (4 vols. 8vo., Paris) is nearly worthless. The *Mémoires biographiques, littéraires et politiques de Mirabeau*, by Lucas-Montigny, his adopted son (9 vols. 8vo., Paris, 1834-'5), are as yet, in spite of serious defects, the most valuable source of information on the subject. To this must be added *Correspondance entre le comte de Mirabeau et le comte de La Marck pendant les années 1789-'90-'91* (8 vols. 8vo., Paris, 1841), and Dumont's posthumous *Souvenirs* (1881).

MIRACLE (Lat. *miraculum*, from *miror*, to wonder), in the stricter usage of the word, a work of divine power, interrupting (or violating) the ordinary course of nature, and directly designed to attest the divine commission of him who works the miracle. It is not in violation of the law of cause and effect, for it has an omnipotent cause; it is not logically disproved by the uniformity of nature, for that uniformity is restricted, *ex hypothesi*, to a different sphere; it is not a mere isolated event, but has a providential or religious design; and that design is not directly to prove the truth of the message, but rather to enforce the credibility of the messenger. The very idea of a miracle, in the sense of the Christian evidences, supposes a contrast between the natural and the supernatural; for a miracle has a supernatural origin; yet, appearing in the forms of space and time, it is subject to the scrutiny of the senses, and an object of human testimony. In the infancy of

physical investigation, and under the influence of instinctive religious belief, portents and prodigies have been quite uniformly ascribed to a supernatural source. Miraculous power has been attributed to the priests of superstitious rites, as well as to the founders of new forms of faith. In the Scriptures of the Old and New Testament, both the *teras*, or *prodigium*, and the *σημειον*, or sign of divine power, are included in the general idea of miracle, but not dissociated. Christ says: "The works that I do bear witness of me, that the Father hath sent me." The apostles enforced their claims by signs and wonders and mighty works. The earlier opponents of Christianity, unlike the later, did not contest the fact of miracles, but, on the contrary, equally appealed to the prodigies of heathenism. The conflicting testimony as to the continuance of miracles in the early church is to be explained in part by the different senses in which the word is used. The two most careful recent English writers on these ecclesiastical miracles come to entirely different results; Dr. Blunt maintaining that miracles never ceased; and Bishop Kaye, that the power cannot be traced beyond the disciples upon whom the apostles laid their hands. Augustine, *De Doctrina Christiana*, c. 25, says: "Since the establishment of the church, God does not wish to perpetuate miracles even to our day, lest the mind should put its trust in visible signs, or grow cold at the sight of common marvels;" but in his *Retractationes* he remarks: "This I said, not because none are wrought now." Eusebius relates that Natalius, a Theodotian, was beaten through the night by angels, and renounced his heresy. Stricter notions and definitions were introduced in the progress of theological scrutiny. Chrysostom says that "a miracle is a demonstration of the divine dignity," and that "no vestige of the power remains." Augustine, *De Civitate Dei*, 21, 8, argues that a miracle is not against nature in its highest aspect: "How is that against nature which comes from the will of God, since the will of such a great Creator is what makes the nature of every thing? In miracles God does nothing against nature; what is unaccustomed may appear to us to be against nature, but not so to God, who constituted nature." Abelard maintained that, in relation to the divine omnipotence, naught is miraculous. Aquinas sharpens the contrast between the miraculous and the natural: "Miracles are all things done by divine power, beside the order commonly preserved in the course of affairs." The schoolmen set up two criteria of miracles, that they are: 1, contrary to nature; 2, by the power of God. After the reformation, in connection with the progress of modern philosophy, both physical and metaphysical, the necessity of yet further distinctions and limitations became manifest. Lord Bacon in his "Advancement of Learning" asserts: "There never was a miracle wrought by God to convert an atheist, because the light of nature might have led him to confess a God;

but miracles are designed to convert idolaters and the superstitious, who have acknowledged a deity but erred in his adoration; because no light of nature extends to declare the will and worship of God." Hobbes arbitrarily restricted the benefit of miracles to the elect: "A miracle is a work of God (beside his operation in the way of nature), ordained in the creation, for the making manifest to his elect the mission of an extraordinary minister for their salvation." Spinoza in his *Tractatus Theologico-politicus* led the way in the historical criticism of the biblical narratives, on the basis of the definition: "A miracle signifies any work, the natural cause of which we cannot explain after the example of any thing else to which we are accustomed; or, at least, he who writes about or relates the miracle cannot explain it." The German rationalism, in its earlier form, attempted the explanation of the gospel miracles by material and spiritual causes. Some alleged that Jesus had unusual knowledge of the powers of nature, or effected his cures by his spiritual influence over men's souls. Others, as Paulus, explained them by the supposition, that the disciples confounded natural events with supernatural; e.g., the two angels in the tomb, clad in white, were an illusion caused by linen garments hanging there; or by such violent interpretations as that the walking upon the sea meant walking on the border of the sea. Some, again, found in them only a symbolical or allegorical sense, and interpreted them as images of spiritual truths. In the mythical theory of Strauss, they are denied as facts, and explained, not as wilful deceptions, but as a spontaneous expression of popular religious feeling, ascribing to Christ what is false in fact, but true in some very general philosophical idea. His criticism of the Gospels proceeds on the assumption, that nothing can have historical reality which is either miraculous or prophetic. With such a canon of criticism, it was not difficult to eliminate from the evangelical records all events of a supernatural character. In meeting such objections, and others to be noticed below, various definitions have been given to miracles, and different positions assigned them in the sphere of the Christian evidences. They have been defined from their cause, as a work of direct divine energy; from their characteristics, as compared with natural events, as superseding or violating the ordinary laws of nature; from their immediate effects, as producing wonder and an impression of the divine presence; and from their final cause, as designed, according to some, to evoke faith, and according to others, to accredit the miracle-worker. Many defenders of Christianity yielded to the objections so far as to define all miracles as relative to human knowledge, or to the effect to be produced upon man's soul. As to the position of miracles in the evidences, some divines, in the reaction against rationalism, have laid the chief stress upon these external signs of divine power, making the miracle to be the chief source of an indubitable

belief, while others have put the truth of the doctrine in the front rank, and made the doctrine the test of the miracle, rather than the miracle the proof of the doctrine. Thus in the more recent English discussions, Dr. Wardlaw would test the doctrine by the miracle, while Dean Trench advocates the converse order. But it seems difficult, and even illogical, to construct on this point an absolute dilemma; for, on the one hand, the mind can and does receive spiritual and divine truth on its own evidence, and for its own sake; while, on the other hand, all who are enlisted in this debate allow that miracles have an important position in the external evidences for the Christian faith. Their value must then be found in their relation to the commission of the worker of the miracles, as a chosen agent for communicating divine truth. To the question, how the miracle proves the credibility of the worker, Dr. Wardlaw replies, that it is an example of the supernatural, and thus the same in kind with what it is intended to confirm; it involves prophecy as to an event, and "prophecy is a miracle of knowledge, while the miracle is a prophecy of power."—Objections to miracles, urged by individual thinkers in all ages, have assumed a more formidable aspect in modern times, in connection with historical criticism on the one hand, and the progress of the physical sciences, disclosing the uniformity of nature, on the other. As far as exegetical and historical criticism is concerned, these objections can be met only by detailed investigation. The more general objections have respect either to the abstract possibility of miracles; or to the violation of the laws of nature supposed to be involved; or, again, to the possibility of their proof, allowing them to be possible in the abstract. As far as the abstract possibility of miraculous intervention is concerned, the whole question belongs, not to the specific sphere of the Christian evidences, but to the more general province of natural theology. An atheist, a pantheist, a fatalist, may concede the inexplicable, but he cannot grant the miraculous; for, considered as a work of divine power, it is to him an effect without a cause. It is on the basis of the pantheistic theory that Strauss, for example, asserts the *a priori* impossibility of miracles, when he says: "The absolute cause never disturbs the chain of second causes by single, arbitrary acts of interposition, but rather manifests itself in the production of the aggregate of final causalities and of their reciprocal action." But, if the absolute cause be a wise intelligence, the miracle is, of course, not "a single, arbitrary act," but a part of God's whole providence. The uniformity of nature has been frequently adduced, as if it were an axiomatic truth, in opposition to the evidence for miracles. This is strongly urged in recent times by Prof. Baden Powell, in his last work on "The Order of Nature." But the uniformity of nature, as far as any given external facts are concerned, is not an absolute truth, is not an intuitive perception; it is simply a matter of

induction. The formula presupposed in the induction is an absolute truth; that formula is simply this: that the same causes, in the same circumstances, produce the same effects. But that formula is not violated in the case of any alleged miracle, for the effect is ascribed to a different, that is, to a divine cause. Thus Brown, in the notes to his essay on "Cause and Effect," truly says that a miracle is a new effect, supposed to be produced by a new cause; and John Stuart Mill, in his "System of Logic," concedes that in the "alleged miracles the law of causation is not contradicted." To meet the same objection, it has often been maintained, that, at any rate, only the order of the lower, physical nature is interrupted; that a higher law sets aside or uses the lower laws; that the material and phenomenal is turned into the service of the ethical and spiritual. Using incidentally such *a priori* objections, the most acute sceptic of modern times made his argument against miracles turn rather upon the possibility of their proof, than upon their mere abstract possibility. David Hume in his "Essays," while admitting the abstract possibility of miraculous intervention, takes the ground that testimony, through which alone we can know a miracle, is often fallacious, while constant experience is in favor of that uniformity of nature which the miracle subverts. His objection was not fully met by the counter position, that we instinctively credit human testimony. But when he claims that all experience is against miracles, he either begs the question, or, if he allows the possibility of exception in the cases in dispute, he logically breaks the spell of his assumed uniformity of nature. It has also been urged that, in the mode in which Hume makes use of his positions, it would be impossible to prove many facts which are generally admitted; for example, the introduction of any new series or orders of beings in the created universe; since there has been no experience reaching to such facts. At any rate, if the *a priori* objections to the possibility of a miracle are abandoned, and the whole question is made to turn upon the credibility of Christ and the apostles, the argument is transferred to a sphere in which the advocates of miracles have always been willing to meet their opponents. For, while the uniformity of nature may raise an antecedent presumption against a miracle, that presumption, it is claimed, is dissipated when we consider the need and the object of this supernatural interposition—that is, to redeem a fallen world; and thus miracles, as Paley argues, have the same degree of probability with a revelation. And especially is it held to be consonant with the character and claims of Christ, that he should manifest such unrivalled power over the natural world—a power he always used for beneficent ends.—For a full discussion of miracles, the reader may consult Campbell, "Dissertation on Miracles;" Douglas, "Criterion, or Miracles Examined;" Leland, "View of Deistical Writers;" Farmer, "Dissertation on

the Miracles;" Leslie, "Truth of Christianity;" Wardlaw, "On Miracles;" Alexander, "Christ and Christianity;" N. W. Natura et Necessitate*; Tholuck, *Glaubenswürdigkeit der evangelischen Geschichte*, and on the miracles of Mohammed and those in the Catholic church, in his *Vermischte Schriften*; J. P. Lange, *Christliche Dogmatik*. On the continuance of miracles in the church, beside the works of Blunt and Bishop Kaye, see Middleton, "Miraculous Powers;" J. H. Newman (in reply to Taylor's "Ancient Christianity"), "Essay on Miracles," prefixed to his translation of Fleury's *Histoire ecclésiastique*; H. Bushnell, "Nature and the Supernatural."

MIRACLES AND MORALITIES, religious and allegorical plays, which constituted the drama of the middle ages. They were at their origin often called miracle plays and moral plays, and in later times have more frequently been indiscriminately styled mysteries. The subjects of the miracles were either the narratives of the Old and New Testaments or the legends chiefly of the lives of the saints; and the moralities, which appear later, intermingled allegory with sacred history, or were represented exclusively by allegorical personages. In the first ages of Christianity, baptism was refused to any one concerned with the theatre. Both the Greek and Latin fathers anathematized the dramatic art, and Chrysostom declared it a shame that people should listen to a comedian with the same ears that hear a preacher. The church succeeded in the 4th century in extinguishing the theatre everywhere except in Constantinople, where the genius and the arts of antiquity lingered in decay. This triumph had hardly been accomplished when from the bosom of the church sprang a new drama and spectacle. The sacred ceremonies and commemorations of the Christian faith, in the name of which profane games had been proscribed, were themselves transformed into dramatic representations. Gregory of Nazianzus, patriarch of Constantinople, composed a play on Christ's passion, and others of the same kind, to supersede those of Sophocles and Euripides, which had till then maintained themselves on the stage. The progress of this fantastic Christian drama cannot be traced till about the 11th century, when Theophylact of Constantinople introduced the feast of fools, the feast of asses, and other religious pastimes, which were celebrated in churches. To these sports the clergy added the acting of miracle plays, which originally were not only composed by ecclesiastics, but were performed by them in churches and the chapels of monasteries. They were afterward exhibited by trading companies, each guild sharing the expense, and undertaking a portion of the performance; and they served the purpose of amusing the peo-

ple on public occasions and festivals, while the clergy were at length forbidden by popes and councils to take any part in them. Jugglers and minstrels attended the ambulating companies, and exerted all their skill on these occasions. The stages, either temporary or portable on wheels, usually consisted of 3 platforms, raised one above another. On the uppermost sat the *Pater Cælestis*, surrounded by his angels; on the second appeared the saints and glorified men; while living men occupied the lowest. On one side of the stage appeared a dark, pitchy, flaming cavern, from which issued hideous howlings, as of souls tormented by demons; its occupants were the greatest jesters and buffoons of the company, and constantly ascended upon the stage to act the comic parts. It is probable that miracles were introduced, perhaps by returning pilgrims, from Constantinople into Italy, and thence into France and England. The oldest that are known are in Latin, but in the 12th and 13th centuries they became common in the modern languages; and with some exceptions there is a general resemblance in subjects, characters, and theatrical machinery between those of different countries. It is probable that they had a common origin, and were introduced about the same date, being communicated from one religious body to another. The sacred Latin comedies of Roswitha, a German abbess of the 10th century, were perhaps performed in her own convent. There are extant 3 Latin miracles written early in the 12th century by Hilarius, a disciple of Abelard, the subjects of which are the raising of Lazarus, the life of St. Nicholas, and the history of Daniel. It is certain that the miracle of St. Catharine, by Geoffrey, abbot of St. Albans, was performed both in Dunstable, England, and in Paris about the same time, and that it was then no novelty. Other Latin plays are preserved which seem to have been very popular, both as scholastic exercises among the younger monks, and as popular exhibitions, the greater part of the story being told by pantomime. The mystery of the wise and foolish virgins, which are used alternately Latin and Provençal, indicates the period of transition to the vernacular languages, and may stand at the head of European dramatic literature.—The miracle of the passion was one of the earliest and most wide-spread, and from it the first theatrical company of Paris, established in 1422, was called the brethren of the passion. It embraced the principal events in the life of Christ, and was so long that its representation occupied several days; 87 personages appeared in it, among whom were the 8 members of the Trinity, 6 angels or archangels, 12 apostles, 6 devils, Herod with all his court, and diverse fictitious characters. It appears to modern readers rather grotesque than grand, yet it was exhibited with splendid pomp, and served to impress upon the minds of spectators the events and doctrines that were deemed of greatest importance. The Virgin Mary is a favorite character

in French mysteries, and several of them bear the title of *miracles de Notre Dame*. Others are entitled mysteries of the conception, of the nativity, of the resurrection, and of divers events in the legends of the saints and in the narratives of the Old and New Testaments. The splendor of the theatrical decorations and appliances for inspiring terror increased during the 15th century. In one of the Parisian mysteries St. Barbara was hung up by the heels on the stage, and after uttering her remonstrances was torn with pincers and scorched with lamps before the audience. In a mystery exhibited at Mentz in 1487, an immense dragon sprang out of hell, and threw the spectators into consternation by spreading his wings close by them. The mystery of the "Act of the Apostles" was acted for many successive days in 1541 before the nobility, clergy, and a large popular assemblage in Paris. The *dramatis personæ* are God the Father, Son, and Holy Ghost, the Virgin and Joseph, archangels, angels, the apostles and disciples, Jewish priests, emperors, philosophers, magicians, Lucifer, Satan, Beelzebub, Belial the attorney-general of hell, Cerberus the porter, and a multitude of other celestial, terrestrial, and infernal personages, amounting altogether to 485 characters. A large number of French miracles exist in manuscript, and many have been printed or reprinted during the present century.—The Germans have numerous miracle plays, two of which are peculiar to their own literature, not being traced in the contemporary productions of other European nations. The subject of the first of these is Dr. Faustus, which represents the life, death, and damnation of a daring libertine. The subject of the second is the canonization of Pope Joan, which was written in 1480 and attained general popularity. It has 25 characters, among which are the devil and his mother Lilis, 8 good angels, the Virgin Mary, her Son, Pope Basil, 4 cardinals, a Roman senator, and Death. The scene shifts between earth, hell, purgatory, and heaven. It begins with a council of devils, who agree to tempt Jutta, the heroine, to profane the papacy. She assumes boy's clothes, accompanies a young clerk to the university of Paris, acquires a doctor's degree, proceeds to Rome, and is made successively cardinal and pope. The Virgin Mary sends an angel to ask Jutta whether she prefers perdition or penance and final pardon. She resolves to repent, but Death suddenly seizes upon her soul while she is lying-in, and carries it to the devils in hell. The Virgin again intercedes, and sends an angel from the throne of grace to release her from torment. The play terminates with the magnificent spectacle of her ascension into heaven. This bold drama had so much effect in Germany, that when the Protestants employed the fiction of a female pope to bring the papacy into contempt, each literary industry was required to eradicate the delusion. Germany was celebrated for its *Fastnachts Spiele*, or carnival plays, in which religious subjects were treated with un-

bounded license. In one of them, which is extant, Virgil accompanies the shepherds to adore the new-born Christ.—The records of English miracle plays are at least as ancient as those of France or Germany. Their early popularity is attested by Langlande and Chaucer, and subsequently immense crowds assembled with the greatest enthusiasm to witness their performance. They may be traced from the beginning of the 12th century, but whether they were originally in Latin or in Norman French is not certain. Higden was obliged to visit Rome 8 times before he could obtain leave to have them in the English tongue. The Chester, Coventry, and Towneley mysteries form 3 great series. As early as 1268 religious dramas were exhibited by the incorporated trades in Chester, where they continued with some interruptions until 1577. They consist of 24 dramas, which were annually represented from Whit Monday until the following Wednesday. Among the subjects are the fall of Lucifer, performed by the tanners; the creation, by the drapers; the deluge, by the dyers; Abraham, Melchisedek, and Lot, by the barbers and wax chandlers; Moses, Balak, and Balaam, by the hatters and linen drapers; the killing of the innocents, by the goldsmiths; the descent into hell, by the cooks; the ascension, by the tailors; Antichrist, by the dyers; and the day of judgment, by the websters. The series thus covered the whole period from before creation until the consummation of all things. The sacred dramas of Coventry drew immense multitudes to that city, as well from its central position as from the patronage of royalty. They were performed by the trading companies of Coventry on Corpus Christi day, from 1416 to 1591. The subjects are nearly identical with those of the two other series, but are more numerous, the plays being 42 in number. It is remarkable that the friars encouraged them as a means of stigmatizing the labors of Wycliffe, branding his Testament as a false one, anathematizing scriptural inquiry as heresy, and enlivening the attachment of the people to the "good old customs" of the church. The Towneley mysteries, so named from the family having possession of the manuscript, belonged according to tradition to the abbey of Widkirk, and are supposed to be the plays written and performed by the Augustinian friars of Woodkirk. Fairs were annually held there on the feast of the Assumption and on the feast of the Nativity of the Blessed Mary, and internal evidence indicates that these were the occasions of their exhibition. The series consists of 82 plays, bearing a near resemblance to those of the Chester and Coventry collections. The artificers and tradesmen of York also annually celebrated a Corpus Christi play, and the same day was similarly observed by the incorporated trades at Newcastle-upon-Tyne and several other large towns, and by the parish clerks and gray friars of London. Christmas also was in this way observed in connection with the festivities

of the abbot of misrule. At York every trade was obliged to furnish out a pageant to adorn the occasion, and these pageants were 54 in number in 1415. The first part of the miracle of that year, in which God the Father appears creating the heavens, the angels, archangels, Lucifer, and the angels that fell with him, was performed by the tanners. The second part, in which God the Father created the earth and all which is therein in the space of 5 days, was represented by the plasterers. The third part, in which God the Father creates Adam and Eve and breathes into them the spirit of life, was played by the card-makers. The 54th part, which includes Jesus, Mary, 12 apostles, 4 angels with trumpets, 4 angels with lances and scourges, 4 good and 4 bad spirits, and 6 devils, was performed by the mercers. There are 8 miracle plays in the Digby MSS. in the Bodleian library relating to the conversion of St. Paul. Only a single example of the Newcastle mysteries remains, entitled "Noah's Ark, or the Shipwrights' Ancient Play," in which God, an angel, Noah and his wife, and the devil are the characters. According to Malone, the last mystery performed in England was that of Christ's passion in the reign of James I., but they had generally ceased to be written from the time of John Bale (1538). The principal English miracle plays have been published, and no other portion of mediæval literature is so strikingly marked by mingled drollery and solemnity. From the reign of Henry VI. they had been encroached upon and superseded by moral plays or moralities, in which abstract allegorical personages took the place of Scripture characters. The change was gradual. In one of the Coventry miracles the representatives of *Veritas*, *Justitia*, *Pax*, and *Misericordia* appear in the parliament of heaven. Death and the mother of Death were successively added; and as these characters increased, biblical history fell into the background and was at length eliminated. Moralities reached their highest perfection in the reigns of Henry VII. and Henry VIII., though they subsequently exhibited greater complication and ingenuity. They contained two standing characters, the Devil and the Vice. The former, the leader of the Seven Deadly Sins, was made as hideous as possible, shaggy, bottle-nosed, and with a tail. He entered upon the stage crying "Ho, ho, ho!" and his part consisted largely in roaring when castigated by the Vice. The latter, though represented as "most wicked by design and never good by accident," was chiefly employed in belaboring the Devil. He was generally dressed in a fool's habit, and the character was gradually blended with that of the domestic fool. Moralities were abundant in France and England in the 15th and 16th centuries. The interludes of John Heywood mark the transition in England from them to legitimate tragedy and comedy. In Paris the devout buffoonery of the brethren of the passion gave offence and caused their suppression in 1547, and the company which pur-

chased the Hôtel de Bourgogne was enjoined to abstain from "all mysteries of the passion, or other sacred mysteries." In French the *Moralité tressingulière et tresbonne des blasphémateurs du nom de Dieu* is one of the most celebrated; and in English Skelton's "Magnificence," designed to show the vanity of worldly grandeur, and in which the characters are Fei-city, Liberty, Measure, Adversity, Poverty, Despair, Mischief, Good-hope, Redress, Circumspection, Perseverance, Fancy, Folly, and Crafty-conveyance.—Mysteries are still occasionally performed at several places in Europe, the most celebrated being that of Ober-Ammergau, in the Tyrol, which is represented every tenth year. It is the production of successive priests of the parish, and embraces the entire history of Christ from his entry into Jerusalem to his appearance to Mary Magdalene after the resurrection. Every scene is preceded and prefigured by a typical tableau. This *Passions-Spiel* originated in a vow made by the inhabitants in 1633, when mysteries were not uncommon, to commemorate their deliverance from a plague by thus representing the last scenes in the life of the Saviour once every 10 years for ever.—See Onésime Le Roy, *Études sur les mystères* (Paris, 1837); Achille Jubinal, *Mystères inédits du quinzième siècle*: 2 vols., Paris, 1837; Leroux de Lincy, *Recueil de farces, moralités et sermons joyeux* (4 vols., Paris, 1837); Heinrich Hoffmann, *Fundgruben für Geschichte Deutscher Sprache und Literatur* (2d vol., Breslau, 1837), containing 4 German miracles; William Hone, "Ancient Mysteries Described" (London, 1823); Thomas Sharpe, "A Dissertation on the Pageants or Dramatic Mysteries anciently Performed at Coventry" (Coventry, 1825); Collier, "History of English Dramatic Poetry" (3 vols., London, 1818); "The Towneley Mysteries," published for the Surtees society (London, 1836); Wm. Macmillan, "A Collection of English Miracle Plays" (London, 1838); Thomas Wright, "The Chester Mysteries" (London, 1843), and "Early Mysteries and other Latin Poems of the 12th and 13th centuries" (London, 1844); and Edwin Norris, "The Ancient Cornish Drama" (Oxford, 1859). A large number of the French miracles and moralities have been published separately, among which are *Les blasphémateurs* (1831) and *Le sacrifice de Joseph* (1835), both exact reproductions in form and type of the MSS. in the imperial library. Only 90 copies were issued, one of each is in the Astor library, New York.

MIRAGE (Fr., from Lat. *miror*, to wonder), an optical illusion due to unequal densities and refracting powers of adjacent strata of the air, usually of those close to the surface of the land or sea, and in consequence of which 2 and sometimes 3 images of a distant object are seen. In the latter case, the middle one being inverted, as is the image of a distant shore in water, it would be if seen in a horizontal mirror standing between it and the eye. Rays of light passing from a denser to a rarer medium are

bent, at the surface of division of the two, from a perpendicular to such surface, and the reverse. But as the angle in the denser medium is thus always less than that in the rarer, a ray proceeding from the denser to the rarer may strike the surface between them at an inclination so great that the corresponding angle in the rarer shall exceed the whole space, 90° , within which transmission could occur; such a ray cannot be transmitted, but will undergo total reflection, even at the surface of a perfectly transparent medium; so that to all rays coming from without a certain angle called the limiting angle, such a surface acts as a mirror; or rather it reflects absolutely the whole of such light, which no ordinary mirror does. These two principles of the refraction and total reflection of light explain all the cases of the phenomenon under consideration, which is often termed that of unusual refraction, and the chief examples of which are commonly known as looming or mirage, and the *fata Morgana*. (See *FATA MORGANA*.) The looming of ships or of distant shores on the sea or lakes, is seen when, owing to the presence of dense vapors or to a considerable difference of temperature of the water and air, the strata of the latter near the surface are of very unequal densities. Hence, it is here more frequent in the morning, or when the air is misty, as after rains, in the summer and autumn. At these seasons, the water, retaining its heat more perfectly over night than the air, may be in the morning several degrees the warmer, the stratum of air just over it will be rarer than that higher up, and looming is then very sure to be seen, but best by an eye quite close to the level of the water, imperfectly at heights greater than 6 or 8 feet, and rarely as high as 24 feet. In one form, a ship or other object near the water seems greatly elongated upward, or a second inverted image meets it from above. Sometimes the proper image of the object is elevated, while the second image appears inverted beneath it, and surrounded by a sheet of sky which is mirrored and repeated with it. This second image may be truncated below by the horizon, or entire; in the latter case, a third appearance, erect, and usually only partly emerging above the apparent horizon, is sometimes seen. The unusual images commonly have serrated or indistinct borders, and are marked by a tremulous motion—qualities more apparent, as indeed is the whole phenomenon, when viewed through a telescope. A horizontal line of separation runs between the first two sets of images, which is above the horizon; the apparent horizon is on the other hand depressed. Above and between these, a low shore with its inverted image may appear like a body of land actually suspended in the air. The nearer the objects, the less the angular interval between the line of separation and the apparent horizon. M. Bravais, who has most thoroughly investigated the subject, found that for a distance of 25 miles the angle was $7'$, for 5 miles $6'$, and that it disappeared at 800 yards; within which

distance, therefore, no appearance of mirage can occur. These appearances are explained by supposing 2 or 3 sets of rays setting out from the objects, only one set of which, in ordinary states of the air, would meet the eye, but all of which in certain cases, owing to unequal densities of near strata, and to consequent refraction and perhaps total reflection, may be brought by different paths to the eye. As all objects are seen in the direction from which the light appears to meet the organ of vision, 2 or 3 images in different places are the result. The inverted image is usually or always due to reflection. Thus, Dr. Wollaston obtained 3 images of an object seen through a square glass vessel holding successive layers of sirup, water, and spirit; the appearance occurring at either line of junction of two unlike fluids, and where by slow intermixture a gradual variation of density occurs. The same effect may be seen by holding a word in large type on the further side of the heated layer of air moving over a hot poker, or by regarding objects through the hot air or steam escaping from the boiler of a locomotive; and the familiar tremulous appearance of distant fences heated by the summer's sun, and of objects seen through air over any hot bodies, are imperfect instances of the same phenomenon. In 1822, in the arctic regions, Capt. Scoresby recognized by its inverted image in the air the ship *Fame*, which afterward proved to be at the moment 17 miles beyond the visible horizon of the observer. Dr. Vince, on Aug. 6, 1806, at 7 P. M., saw from Ramsgate, at which place usually only the tops of its towers are visible, the whole of Dover castle, appearing as if lifted up and placed bodily on the near side of the intervening hill. So perfect was the illusion, that the hill itself could not be seen through the figure. This form of mirage may be lateral, as well as vertical, arising from unequal density of two contiguous vertical bodies of air. Thus, on Lake Geneva, a boat has been seen doubled, the two images some distance apart; persons have been duplicated in the same way; and any one in a hot day, by placing his eye near to a heated vertical wall, may see lateral mirage of objects at a distance and nearly in a line with the wall. Upon land, the mirage is best seen over desert plains in hot climates; the intense heat of the sands greatly rarifies the air in contact with them, and rays of light coming from distant objects, as villages, or the trees upon oases, are gradually bent by approaching this rare stratum, until they strike it at an angle greater than the limiting angle; total reflection then occurs, the air near the sand acting as a mirror or a body of water, in which inverted images of the objects are seen. Thus is presented to the inexperienced traveller the appearance of tranquil lakes, sometimes almost surrounding him; this, however, necessarily changes to the real aspect as he approaches, as if the waters were continually receding before him.

MIRAMIOHI, a port, bay, and river of New Brunswick. The bay is about 21 m. long and

20 m. wide at its mouth, Point Portage being on the N. and Escuminax point on the S. It contains Fox and Portage and a number of smaller islands. The river is formed by the junction of 2 branches about 50 m. from the sea. At its mouth, which is obstructed by a sand bar, are landing places for cargoes, but the chief business places are Newcastle and Chatham, 20 m. up the stream. It is navigable for a distance of 40 m. from its mouth. Great forests of pine cover the banks of the river and surrounding country. In 1825 a conflagration destroyed the forests on the N. bank and all the towns and villages within an extent of 85 m. long, and in some parts as much as 25 m. broad. The smoke and cinders were observed at Quebec, more than 250 m. distant, and even as far S. as the Bermudas. The pines in the burned district have been succeeded principally by poplar, white birch, and maple.

MIRAMON, MIGUEL, a Mexican soldier, born in the city of Mexico about 1830. He is the son of Gen. Miramon, and was educated at the military academy of his native city. He early entered the army and served under Alvarez, whose private secretary had been among his classmates. His conduct, however, gave umbrage to his superior, and subsequently he was made a prisoner by Gen. Comonfort, but succeeded in effecting his escape. Noted for his courage, but deficient in character and statesmanlike qualities, he became the nominal leader of the anti-liberal and clerical party, and rose to the supreme command of the revolutionary forces during the civil war of 1858-'60. After a protracted struggle his defeat was reported to have taken place, Aug. 18, 1860, after which he shut himself up in Mexico with about 7,000 men, the army of the liberal party advancing with rapid strides toward the capital, with a probability of his final discomfiture.

MIRANDA, FRANCISCO, a Spanish American patriot and French general, born in Caracas, South America, about 1750, died in prison in Cadix, Spain, in 1816. He was expelled from South America on account of his participation in the efforts made to deliver the Spanish colonies from the yoke of the mother country, and finally entered the French service as general of division. He took a part in the campaign of 1792, and in 1793 accompanied Dumouriez to Belgium, where he commanded a division of the army at Neerwinden. He was held responsible for the loss of that battle, and was accused of being implicated in the treachery of Dumouriez, and brought before the revolutionary tribunal, but acquitted. Soon, however, he again gave umbrage to the revolutionists, and was eventually compelled to seek refuge in England. Afterward he endeavored to obtain the joint assistance of Great Britain and the United States for the liberation of the Spanish American colonies; his hopes, however, were disappointed; he returned to France in 1804, but was again expelled from the country by the first consul. In 1806 he fitted out his memorable

expedition in the United States, and returned to South America, with the view of establishing a republic at Caracas. He succeeded in 1812 in maintaining himself against Spain at the head of an army of insurgents, and was supported in his patriotic attempts by the British and American governments; but he was delivered by Bolivar into the hands of the Spaniards, and carried to Cadix, where he died after 4 years' imprisonment. —See "History of Miranda's attempt to effect a revolution in South America" (New York, 1846).

MIRANDOLA, GIOVANNI PICO DELLA, count and prince of Concordia, an Italian scholar, born at Mirandola, Modena, Feb. 24, 1463, died at Florence, Nov. 17, 1494. Almost from childhood he displayed an extraordinary memory. At the age of 14 he was sent to Bologna to study canon law; but soon abandoning that pursuit he repaired to Ferrara and applied himself to philosophy, theology, and languages. Voltaire cites the example of this precocious youth as evidence of the superior state of learning in Italy at that period. After becoming master of all the learning of the time, he proceeded to Rome in 1486, and propounded 900 theses as subjects of controversy to the learned men of the eternal city. His challenge was not accepted, but more rigid theologians denounced 18 of his propositions to the pope, Innocent VIII., as heretical, and though he ultimately succeeded in proving their orthodoxy, he suffered much persecution. These trials made a deep impression on his mind and induced him to give up the study of profane literature and to devote his attention in future to religion and philosophy. Resigning his principality in favor of his nephew, he lived in the utmost retirement at Florence until his death, a year before which Pope Alexander VI. had absolved him of all heresy. A collected edition of his works was published at Basel in 1601. His biography has been written by the Rev. W. Parr Greswell (Manchester, 1845).

MIRBEL, CHARLES FRANÇOIS BRUNEAU DE, a French naturalist, born in Paris, March 27, 1777, died Sept. 12, 1854. He was originally by profession a painter and designer, and about 1800 became superintendent of the gardens and conservatories of Malmaison. About the same time he lectured on botany in Paris. In 1802 he became a member of the institute, and afterward was appointed assistant professor of animal and vegetable physiology to the faculty of sciences in Paris. Between 1817 and 1827 he held a variety of public offices, but in the latter year resumed his scientific pursuits, and in 1828 was appointed professor of culture at the museum of natural history. He was one of the first to apply the microscope to the examination of the internal structure of plants. Several years before his death he resigned his professorships, and in the latter part of his life carried on an acrimonious controversy with Gandichaud on the growth of vegetables. His works comprise: *Traité de physiologie végétale* (2 vols. 8vo., Paris, 1802); *Exposition de la théorie de l'organisation végétale* (8vo., 1827).

sterdam, 1808); and *Éléments de physiologie végétale et de botanique* (2 vols. 8vo., Paris, 1815). He also took an important part in the preparation of Sonnini's *Cours d'histoire naturelle*, designed as a continuation of the "Natural History" of Buffon, 5 of the 18 volumes devoted to the history of plants being written by himself; and he contributed many papers to the *Annales* of the museum and the *Mémoires* of the academy of sciences, including a celebrated one on the "Anatomy and Physiology of *Marchantia Polymorpha*," in which he described the general structure of the plant and the history of the development of its embryo.

MIRIAM, the sister of Moses the Hebrew lawgiver, and of his brother Aaron. She was present on the bank of the Nile when the laughter of Pharaoh found the child Moses, who had been exposed in a basket on the river, and called her mother Jochebed, the wife of Amram, to nurse him for the princess. After the passage of the Red sea, she sang a triumphal song, of which the commencement only is recorded. Having together with Aaron spoken against Moses in the desert, on account of his having married an Ethiopian (Cushite) woman, she was struck with leprosy, and was excluded from the camp 7 days. She died in Kadesh, and was buried there.

MIRROR (Fr. *miroir*), a looking glass or speculum—any bright surface that reflects the rays of light falling from objects upon it. The surface of smooth water is a natural mirror, which the ancient poets sometimes refer to as having been used for this purpose by goddesses and shepherdesses. Metallic mirrors are mentioned in Exod. xxxviii. 8, and Job xxxvii. 18. With the ancient Egyptians one of the principal articles of the toilet was the mirror. Wilkinson states that it was of mixed metal, chiefly copper, carefully wrought and highly polished. It was of circular form and attached to an elaborately ornamented handle, the designs of which were sometimes beautiful female figures, and sometimes hideous monsters, whose ugliness contrasted most strongly with the features reflected by its polished surface. The practice of using polished basins for mirrors is alluded to by Artemidorus; and the ancients also had drinking vessels, as mentioned by Pliny, the inside of which was so cut and polished that the image of one drinking from them was reflected many times multiplied. The composition of some of the ancient mirrors has been found by William Francis to have been: copper 67.12, in 24.98, and lead 8.13 parts in 100; and by Klaproth: copper 62, tin 32, and lead 6 per cent. Their manufacture appears to have been most extensively carried on at Brundisium. Pliny gives to Praxiteles the credit of introducing mirrors of silver. They are spoken of by Plautus, and in the 4th century B. C. they became very common among the Romans, so that they were in use, according to Pliny and Seneca, even by maid servants, and the manufacture of them was one of the important

trades of Rome. Mirrors of gold are sometimes alluded to, but these are probably so named rather from the material of their frame or ornaments than of the reflecting substance. In order to keep the mirrors bright they required frequent polishing, and for this purpose they were generally furnished with a sponge containing pulverized pumice stone, with which they were often rubbed. They were for the most part of small size, and were held by female slaves before their mistresses when dressing; an office, as appears from Ovid, sometimes also performed by the lover. Mirrors were also made of sufficient size to reflect the whole person, *specula totis paria corporibus*, and were affixed to the walls. Such must have been the mirror of Demosthenes mentioned by Plutarch, Lucian, and Quintilian. Reference is also made to apartments lined with mirrors. From several statements of Pliny it appears that various stones were employed as mirrors, set into the walls as panels, and otherwise used to reflect images of objects. The obsidian appears to have been the variety of stone most employed for this purpose. A similar stone called the *itelli*, and by the Spaniards *gallinazo*, was used for the same purpose by the Aztecs of Mexico, of which hard vitreous stone they also fashioned sword blades and razors. There were other stones also of which when polished they made excellent mirrors; but the description of these is too indefinite to determine their names.—Beckmann thinks that the use of the dark obsidian stone for mirrors suggested the use of glass, that this was attempted at the celebrated glass works of Sidon of which Pliny makes mention, and that they were first made of black glass, and afterward of glass covered on the back with black foil. But from the time of Pliny no certain reference is again found to glass mirrors until the 18th century. In the treatise on optics of Alharen, the Arabian, of about the year 1100, mention is made of mirrors of iron (steel) and also of silver, but not of glass; and the same thing is remarked of the "Optics" of Vitello, of about the middle of the 18th century. But in the treatise on optics of Johannes Peckham, an English Franciscan monk, who taught at Oxford, Paris, and Rome, and died in 1292, mirrors of iron, steel, and of polished marble are spoken of and also of glass covered on the back with lead. After this time various writers allude to mirrors of this sort, and describe their being made by pouring melted lead over the hot glass plates. In the 14th century glass mirrors were extremely rare in France, while metallic ones were in common use. The mirror of Anne of Brittany, consort of Louis XII., was of the latter sort. Beckmann describes the following method of preparing small convex glass mirrors as common in Germany in the beginning of the 16th century. A hollow ball of glass being blown, while still hot a metallic mixture of lead or tin or antimony, with a little resin or salt of tartar, was introduced into it, and coated its inner surface, the resin or

salt aiding the fusion of the metal and preventing its oxidation. The glass, being entirely coated within, and having become cool, was cut into small round mirrors. It is not many years since they were sold in Germany by the name of *Ochsenaugen*, ox eyes. They were set in a round painted board, and had a very broad border, and reflected a diminished but very clear image. The coating of glass with an amalgam of tin foil and mercury was practised by the Venetians in the 16th century. The process, as described by Porta, who witnessed it at Murano, consisted in spreading the tin foil smoothly upon a plane surface, and pouring upon it mercury, which was rubbed in with the hand or a hare's foot. The amalgam thus formed was then covered with a sheet of paper, and the glass being laid upon this and pressed down, the paper was drawn out. Weights were then laid upon the glass, and it was left for some time for the excess of mercury to drain off. The introduction of this manufacture into France is noticed in the article GLASS, vol. viii. p. 282. The chief modern improvement in the art consists in the use of very large plates, the process of coating them not differing essentially from that of the Venetians 300 years ago. The present method is as follows: A large stone table, ground perfectly smooth, is so arranged as to be easily canted a little on one side by means of a screw set beneath it. Around the edges of the table is a groove, in which mercury may flow and drop from one corner into bowls placed to receive it. The table is first made perfectly horizontal, and then tin foil is carefully laid over it, covering a greater space than the glass to be coated. A strip of glass is placed along each of 3 sides of the foil to prevent the mercury from flowing off. The metal is then poured from ladles upon the foil till it is nearly a quarter of an inch deep, and its tendency to flow is checked by its affinity for the tin foil and the mechanical obstruction of the slips of glass. The plate of glass, previously cleaned with especial care, is dexterously slid on from the open side, and its advancing edge is kept in the mercury, so that no air or floating oxide of the metal nor other impurities can get between the glass and the clean surface of the mercury. When exactly in its place, it is held till one edge of the table has been elevated at an angle of 10° or 12° and the superfluous mercury has run off. Heavy weights are placed on the glass, and it is left for several hours. It is then turned over and placed upon a frame, the side covered with the amalgam, which adheres to it, being uppermost. In this position the amalgam becomes hard, and the plate can then be set on edge; but for several weeks it is necessary to guard against turning it over, as until the amalgam is thoroughly dry the coating is easily injured.—There are several serious difficulties attending this process. The health of the workmen is so affected by the fumes of the mercury that they can rarely follow the business more than a few years; for this no

remedy has been found so effectual as thorough ventilation and the frequent use of sulphur baths. The glass plates are liable to be broken by the weights placed upon them; and the coating of amalgam is frequently spoiled by the drops of mercury removing portions of it as they trickle down, or by its crystallizing, or by mechanical abrasion. Many methods of silvering have been contrived and patented with the view of obviating these defects; few of them, however, are of any importance. In 1855 a patent was granted in England to Tony Petitjean for a method of precipitating silver, gold, or platinum upon glass, so as to form a coating upon it, by the use of two solutions, the effect of which when mixed upon the glass is to mutually decompose each other. The solutions he employed were different compounds of ammonio-nitrate of silver, tartaric acid, and distilled water; and they were placed upon the plate while this was at the temperature of 150° F. The precipitated silver within 20 minutes covered the glass, to which it adhered; and the solution being then turned off, all that remained to complete the mirror was to wash the surface, and when dry cover it with a coat of varnish to protect it from injury. The silvering thus obtained is not so white, and is rarely so free from blemishes, as the amalgam coating. In 1849 Mr. Drayton made known a similar method, an improvement upon an older process of his which he patented in 1848. He employed ammonia 1 oz., nitrate of silver 2 oz., water 3 oz., and alcohol 8 oz.; these, being carefully mixed, were allowed to stand a few hours, when to each ounce of the liquid was added an ounce of saccharine matter, as of grape sugar, dissolved in equal portions of spirit and water. Baron von Liebig has recently invented a new method of coating glass with silver, and with some associates has established a manufactory of looking glasses near Nuremberg. In his process, after the silver coating is laid on, it is covered with a coating of copper precipitated upon it by the galvanic current. The brilliancy of aluminum has caused the suggestion of its application to the coating of mirrors; but no successful experiments have yet been made with it for the purpose. Mirrors of large size are made in the United States by coating the imported plates. The old amalgamation method with tin foil and mercury is preferred to any of the more recent inventions, by reason of the greater whiteness and brilliancy of the reflection and the greater permanency of the coating.—For telescopes, philosophical instruments, and light-houses, various sorts of mirrors are in use. For reference to them may be found under various heads in this work, as BURNING GLASS, FURNACE, LIGHTHOUSE, OPTICS, REFLECTION, SPECTRUM, TELESCOPE, &c. Concave mirrors serve to concentrate the rays of the sun in one point and produce intense heat.

MISDEMEANOR. Offences less than treason are, in law, divided into felonies (see FELONY) and misdemeanors. Any crime less than

felony is a misdemeanor. Statutes sometimes declare that the offences which they contemplate shall be punishable as misdemeanors, but the term applies equally to all those crimes, whether of commission or of omission, for which the law has not provided a name. Misdemeanors are either those which exist at common law, *mala in se*, or they are those which are created by statute, *mala prohibita*. Under the former class, whatever, in the language of Blackstone, mischievously affects the person or property of another, openly outrages decency, disturbs public order, is injurious to the public morals, or is a corrupt breach of official duty, is indictable as a misdemeanor at common law. This doctrine is particularly pertinent in the United States, because many of the offences which in England were exclusively cognizable by the ecclesiastical courts, or fall within the specific enactments of the penal code, are here construed and adjudicated according to the general principles and analogies of the unwritten law. In the United States it has been held to be an indictable misdemeanor at common law to drive a carriage along the crowded street so as to endanger the lives of foot passengers; to go armed with dangerous and unusual weapons; to disturb a town meeting or a congregation engaged in religious worship. It is an indictable nuisance and scandal to the community to disinter a dead body without lawful authority; to throw a corpse into a river without the rites of Christian burial; to sell knowingly unwholesome provisions; to be guilty of notorious lewdness or drunkenness; to indulge publicly in profane swearing and blasphemy; or to let a house knowing that it is to be used for the purpose of prostitution. This last doctrine, however, is not admitted in New York. So it has been held to be a misdemeanor, indictable at common law, to deposit more than one vote upon a single ballot; to kill a tree standing upon public ground; to treat an animal with wanton cruelty; to send threatening letters; or to give a challenge to fight.—Misdemeanors which are created by statute are of two kinds. The one kind embraces those which consist in the omission or commission of an act enjoined or forbidden by the statute, though the transgression be not specially made the subject of indictment. For when a statute prohibits a matter of public grievance or commands a matter of public convenience, all infractions of its provisions are indictable, unless this mode of proceeding be positively excluded; because the doing what competent authority forbids, or not doing what it requires, is itself an offence at common law. The second kind includes those statutory offences which are made specially indictable. If the punishment is expressly defined, the provision of the statute must be strictly followed. If the statute merely attaches a new penalty to what was already a common law offence, the remedy may be pursued either as at common law or under the statute. In the English law, when a statute makes that felony which was

only a misdemeanor before, the smaller offence is merged, and there can be no prosecution or conviction for the misdemeanor. But the peculiar reasons for this rule of the English practice have no application in the United States; and it is the rule in New York and in Massachusetts (though in the latter state the English practice prevailed until it was changed by statute), that upon an indictment of felony there may be conviction of misdemeanor if there be evidence enough to make out the less offence.—In respect to misdemeanors, the distinction between principals of the first and second degree is unknown; and those who in treasons and felonies would be accessories after the fact, are themselves liable for the commission of a distinct misdemeanor.—The ordinary punishment of misdemeanor at common law is fine and imprisonment, or either of them in the discretion of the court; and these are regularly inflicted when no other penalty is prescribed. In Connecticut it has been decided that the fine must be less than the whole value of a man's property, and that the imprisonment must be for a less term than the whole of his life. Finally, in all sentences for misdemeanor, the court may require the defendant to give bonds to keep the peace. It is inconsistent with the general policy of the law to allow a criminal charge to be referred to arbitration or to any other mode of private settlement. An agreement to compound a felony has always been held entirely illegal and void. Properly speaking, indeed, the injured party has nothing to compromise. A crime, whatever be the degree of its criminality, is committed against the public order, and it is therefore only upon a public prosecution that the matter can be disposed of. Yet in the slighter offences against the public peace, a compromise, it is said, may be valid. Quoting from Mr. Chitty's notes to the English statutes of arbitration, Mr. Justice Patteson said in a late English case, that such penal offences as assault, libel, nuisance, and the like, for which an action of damages would lie, may be submitted to arbitration at common law; and although an indictment has already been preferred, the matter of complaint may still be referred by leave of court. Plainly, nothing can prevent an injured individual from submitting to arbitration the private wrong which may be measured and compensated by damages. But the public wrong done, in the slighter misdemeanors even, cannot, in strictness, be removed from public cognizance except by consent of the proper authority. Hence it seems to be the common law doctrine that though, in such misdemeanors as those just referred to, where the public interest is but little concerned, the criminal process will be waived almost as matter of course upon acknowledgment of private satisfaction, yet express or implied consent of the court to the waiver is still essential to the valid compromise of the matter. This doctrine of the common law is carried out in those statutes by which in several states it is provided, that upon

a criminal charge of assault and battery or other misdemeanor for which a remedy by civil action is given, if the injured party appear before a magistrate and acknowledge that he has received satisfaction, the accused may, or in some cases shall, be discharged on payment of costs.

MISERERE (Lat., have mercy), the name applied in the Roman Catholic church to the 51st Psalm, which commences in the Vulgate with that word, and is specially employed as a penitential hymn. The words of this Psalm have frequently been set to music by eminent composers, the *Miserere* of Allegri, performed annually in the Sistine chapel in Rome in Passion week, being particularly famous; and the term is now commonly applied to any sacred composition of a penitential character.

MISHNA, or **MISHNAH** (late Heb., study), the earlier part of the Talmud, forming a compendium of decisions, based on oral traditions, respecting the laws and religious rites of the Jews, and first systematically arranged by the patriarch Rabbi Judah the Holy and his school, toward the close of the 2d, or according to others in the early part of the 3d century. It is written in Hebrew, and divided into 6 principal parts and 63 subdivisions. Of the former, the 1st treats chiefly prayers and the duties of husbandmen; the 2d, festivals; the 3d, marriage relations; the 4th, judicial subjects; the 5th, matters concerning the temple; and the 6th, the institutions respecting purification. (See **HEBREW**, and **TALMUD**.)

MISKOLCZ, a town of Hungary, capital of the county of Borsod, on the Szinva, near its embouchure in the Sajó; pop. about 30,000. It is situated at the foot of a vine-clad mountain called *Avaa*, and has numerous institutions of learning. The inhabitants, consisting of Magyars, who form the majority, Rascians, Slovaks, Germans, and Jews, are actively engaged in trade and manufactures; and the town is connected by railway with Kaschau on the one side, and Debreczin on the other. In the vicinity are the iron works of Diós Győr, in a picturesque valley, at the upper end of which is a mountain lake, and the mineral waters of Tapolca.

MISSAL (Lat. *missale*), in the Roman Catholic church, a book which contains the services of the mass for the various days of the year. In the ancient church, the several parts of divine service were arranged in distinct books. The *Sacramentarium* contained the collects and the invariable portion of the communion office; the *Antiphonarium*, the anthems to be chanted at the beginning, after the epistle, at the offertory, and at the communion; the *Lectionarium*, the lessons from the Old Testament, the Acts, the Epistles, and the Apocalypse; the *Evangelium*, sections from the four Gospels. Each of these parts was sometimes called *Liber Missalis* (mass book), especially the first. The Roman church had three celebrated sacramentaries: 1, the *Sacramentarium Leonianum*, published by Blanchini in 1785, and sup-

posed by its first editor to have been arranged by Leo I., an opinion which is now rejected by most Catholic writers (Muratori, Ballerini, Lütt, &c.), who ascribe its origin to an unknown author about the end of the 5th century: 2, the *Sacramentarium Gelasianum*, generally ascribed to Gelasius I. (died 496); 3, the *Sacramentarium Gregorianum*, by Gregory I. (died 604). A collection containing all the 4 books used at the mass was called *Missale Plenerium*, and later simply *Missale*. Such missals were in common use long before the council of Trent, which discussed the necessity of a revision, and referred its execution to the pope. The revision was commenced under Pius IV. and published under Pius V. The revised missal was published on July 14, 1570. New revisions were made under Clement VIII. (1604) and Urban VIII. (1684). The Roman missal consists of three principal parts: 1, the *Proprium Missarum de Tempore*, containing the formularies for the masses of the Sundays; 2, the *Proprium Missarum de Sanctis*, containing special formularies of mass for the festivals of a number of saints; 3, the *Commune Sanctorum*, containing general formularies for classes of saints (as apostles, martyrs, confessors, &c.), serving as an appendix to the second part for such saints as have no special service assigned them. The *Ordo Missæ*, containing that part of the mass which is invariable, is inserted in the first part of the missal between Saturday of the Passion week and Easter. (Concerning the Ambrosian, Mozarabic, and Gallican missals, see **LITURGY**. Some dioceses and religious orders have in an appendix special formularies for the masses of saints whose festivals are celebrated by them with greater solemnity than in the rest of the church. (For the illumination of missals, see **MINIATURE PAINTING**.)

MISSINNIPPI RIVER. See **CHURCHILL**.

MISSIONS, FOREIGN. In a theological sense, this term denotes the efforts made by the professors of a religious creed to propagate their doctrines in countries following other religious persuasions. The disciples of Christ received from their master the command: "Go ye into all the world, and preach the gospel to every creature." In compliance with this call, the apostolic church at once began missionary operations on a larger scale than the world had ever seen before. Unfortunately the records of this first brilliant period of the missionary history of the church have been mostly lost; but enough has been preserved to show that the doctrines of Christianity were taught by the apostles themselves and their disciples far beyond the confines of the Roman empire. Toward the close of the 1st century the heroic missionary efforts of the church had called into existence numerous and flourishing congregations in the towns of Asia Minor, Greece, Italy, the islands of the Mediterranean, northern Africa, India, and probably several other countries. In the 2d and 3d centuries we see the missionaries successful in southern Germany, Gaul, Arabia,

and Ethiopia. Under Constantine Christianity became the state church, and the custom was gradually introduced of using coercive measures for the advancement of the Christian doctrines. The missionary zeal seems not to have abated, but it is frequently difficult for the historian to determine what share the missions and what the secular arm had severally in completing the Christianization of the various countries constituting the Roman empire. Ireland (the "isle of the saints") and Scotland soon became the most celebrated nurseries of great missionaries, who in particular labored for the conversion of the Germanic tribes. Emmeranus, Corbinianus, Columbanus, Gallus, Boniface, and Anscarius are among the most celebrated apostles of northern Europe. In the East, Iberia, Armenia, and Persia were the most important missionary fields. After the separation of the eastern church from the western, the interest in the missionary cause almost wholly ceased in the former. The progress of Christianity eastward was arrested, while a considerable portion of its own territory was taken possession of by the Mohammedans. The Nestorians continued for a long time to carry on, especially in China and India, successful missionary operations, of which little is now known. The Latin church continued her spiritual conquests in northern Europe. The Scandinavian kingdoms were gained over one after another in the 10th and 11th centuries. Cyril and Methodius opened to Christianity the way to the great Slavic race, by preaching to the Khazars, Bulgarians, and Moravians. Adalbert, bishop of Prague, was martyred in a mission among the Prussians. From Iceland, whose Christianization was completed about 1000, missionaries accompanied the adventurous Norsemen on their expeditions of discovery; and Greenland is believed to have received at that time the first account of Christianity and the first foundation of a Christian church. The extension of Latin Christianity in northern Europe is however more due to the laws and wars of the princes than to the zeal of missionaries, though in almost every country devoted missionaries were not wanting, who cheerfully risked their lives in preaching to the native pagans. A new missionary zeal awoke in the Roman Catholic church after the foundation of the mendicant orders, which endeavored to excel each other in extending the territory of their church. Innocent IV. in 1245, and St. Louis in 1248, sent mendicant friars as missionaries among the Mongols; and in 1289 John de Monte Corvino translated the New Testament and Psalms into the Tartar language. Several bishops were appointed for China, where the mission assumed large dimensions, but half a century later it was nearly exterminated. Toward the close of the 14th century the Franciscans supported a flourishing mission in northern Persia, with about 10,000 adherents. The missionaries to the East did not confine their labors to the pagans, but also endeavored to bring about a union of the eastern episcopal denomi-

nations, and were partly successful in the case of the Greeks, Armenians, Copts, and others. In the 15th century Portuguese missionaries settled in the islands discovered by their countrymen, and with the aid of the secular arm soon and easily effected the nominal Christianization of Madeira (1418-'20), of the Azores (1482-'57), and of several districts along the African coast (1486-'97). Very extensive new fields for missions were opened by the discovery of America in 1492, and the circumnavigation of the cape of Good Hope in 1497. Great numbers of missionaries volunteered to be sent to the newly discovered countries, and in the East as well as West Indies missionary operations were commenced on a very large scale. In the East Indies the bishopric of Goa was established in 1520 under Franciscan missionaries, several other bishops for the East were appointed, and sent out by the Portuguese government, and a large part of the Christians of St. Thomas were prevailed upon to unite with the Roman Catholic church. In Mexico and Central and South America, the 16th century completed the victory of the Roman Catholic missions, as far as the country was under the dominion of the Spaniards and the Portuguese. In many instances, however, the aid of the inquisition was invoked to suppress the pagan worship.—An extraordinary impulse to missionary labors was given by the establishment of the order of the Jesuits, as all the members of the new order took a vow to go as missionaries into any country whither it might please the pope to send them. As, shortly before the foundation of their order, a large part of Europe had separated from the Roman Catholic church, they directed their efforts equally to the conversion of the pagans and to inducing the Protestants and eastern Christians to submit again to the authority of the pope. St. Francis Xavier, the apostle of the Indies and Japan, surpassed all Christian missionaries who had lived since the apostolic age in the extent of his missionary travels, and in the number of converts whom he baptized. At the time of his death about 100 Jesuits were laboring in the East Indies. Soon after, the east of Asia presented the brightest prospects. The Philippines in 1571 became a Catholic country, under Spanish dominion; and even in the mighty empire of Japan the conversion of a number of princes promised the speedy victory of Christianity, when internal wars and dread of foreign rule called forth (after 1587) a bloody persecution, which ended in the second half of the 17th century in the complete extirpation of Christianity. In China, several Jesuits, especially Ricci and Schall, obtained great influence at the court by means of their astronomical and mathematical knowledge, and among the educated classes of the people by the classic works which they composed in the Chinese language; and this extensive influence was used with great success in gaining converts for their creed. While Spanish missionaries from Mexico were pressing northward, the French in

1608 began to send missionaries to North America, and established prosperous settlements among the Abnakis, Hurons, Iroquois, and other Indian tribes. Biard and Brébeuf were the most celebrated among those who devoted their whole lives to thoroughly organizing the colonies of native Christians. The French missions gradually advanced up the St. Lawrence and along the lakes. In Abyssinia repeated efforts were made from 1550 to 1684, mostly by Jesuits, to bring the national church, which had been isolated from the rest of the Christian world for more than 1,000 years, into an organic connection with the Roman Catholic church. Several princes entered into their views, and a member of the Jesuit order was appointed patriarch; but at length a successful insurrection thwarted the project. Several other portions of Africa received Catholic missionaries in the course of the 17th century, as Morocco (1680) and Madagascar (1648), but without permanent success.—In the 18th century the Jesuit missions in the East greatly declined. In China and India they were involved in a controversy with the Dominicans respecting certain accommodations to native customs, which the Jesuits regarded as lawful, while the Dominicans stigmatized them as idolatrous. Rome decided against the Jesuits; and from that time the prosperity of their missions declined. In China, moreover, a fierce persecution broke out against the Christians, which between 1722 and 1754 diminished their number from 800,000 to 100,000. In Thibet, the Capuchins tried to establish missions, but with only slight success. A larger number of conversions were made in Indo-China, especially in Cochin China and Tonquin, and the Catholic population gradually rose to several hundred thousand, mostly attended by native priests. A firm foundation, amid the continuance of persecution, was also laid in Corea. In Africa a third attempt was made (1750–'54) to unite the Abyssinian church with Rome, but without success. The Portuguese missions on the W. coast of Africa almost entirely decayed. In the Spanish and Portuguese possessions of America the progress of the missions among the Indians was completely arrested by the expulsion of the Jesuits, and the attitude which the governments of Spain and Portugal assumed toward the Roman Catholic church. The French revolution toward the close of the 18th century greatly diminished the power and resources of the Roman Catholic church, in consequence of which nearly all the foreign missions declined, while some were given up entirely. Since 1814 the operations in the various missionary fields have again been taken up with renewed zeal; the number of missionary bishops and priests has been greatly increased, but no extraordinary successes have as yet been announced. In China proper, in Corea, and in India, the Catholic population has, however, considerably risen. Cochin China and Tonquin enjoyed likewise for some time a season of great prosperity, until, about 1858, the persecution to which more or

less the Christians were generally exposed assumed such dimensions that nearly all the priests were killed or obliged to flee, and nearly every congregation was scattered. This led in 1858 to an intervention of the French and Spaniards, who, however, up to 1860, had only possessed themselves of a small tract of coast land, without compelling the government to cease the persecution. Japan was reopened to Catholic missionaries in consequence of the treaties of 1859, and was at once occupied as a mission field. The missions in Turkey, and more particularly those among the eastern churches, were greatly enlarged, and considerable numbers of Armenians, Jacobites, and Nestorians entered into union with Rome. The same step was taken, in 1859, by the king of Tigre in Abyssinia, with 50,000 of his subjects. The conquest of Algeria by the French gave rise to some enterprises for the conversion of the Mohammedans, but without notable results. Special missionary associations were formed in Austria for Khartoom in Nubia, and in France for western Africa; but the majority of missionaries were swept away by the deadly climate soon after their arrival at the missionary stations. In North America, the labors among the Indians were taken up again, especially by the Jesuits, and the missionaries advanced up to the northernmost settlements in the British possessions; but nothing of importance has been done for the pagan Indians in the countries south of the United States. In Australasia numerous congregations of natives have been formed, especially in New Zealand; several smaller islands, as Wallis and Futuna, have been wholly gained for the Roman Catholic church; and, under the patronage of the French, a firm footing has also been obtained in some islands which had been pre-occupied by Protestant missionaries, as Tahiti and the Sandwich islands.—The Roman Catholic church has a number of institutions for the training of missionaries. The oldest and most celebrated among them is the propaganda in Rome. (See PROPAGANDA.) Other institutions of this kind are Greek, German, English, Irish, Scotch, Belgian, and South American colleges at Rome, and the Chinese college in Naples, founded in the first half of the 18th century by an Italian missionary in China. All the pupils are natives of China, who, after being ordained as priests, return to their country as missionaries. The Greek seminary at Palermo educates priests for the United Greeks. The American college at Rome for the training of missionary priests for the United States was opened by Pius IX. in 1859. The seminary of foreign missions at Paris is probably the most fruitful nursery of Roman Catholic missionaries; it supplies a number of the missionary dioceses in China and Indo-China. The college of Old Hall, near Dublin, Ireland, is of growing importance. The number of its pupils amounts to about 100. It mostly trains priests for Irish emigrants to Protestant countries; but many of them are

by the situation of their stations called upon to preach to heathen also, especially those in India. Moreover, most of the religious orders educate a number of their members for foreign missions, and some of them have special houses for this purpose. A number of missionary dioceses in pagan countries are intrusted by the propaganda to the several orders, which engage to send here the necessary number of missionaries. Those most numerous represented in the foreign mission field are the Jesuits, Franciscans, Dominicans, Lazarists, the Picpus society, the Marists, Capuchins, and Carmelites. There are also supported in the missions a number of seminaries for the training of a native clergy, of which that at Penang in British Asia is one of the largest.—The first general association for the support of Catholic missions was formed at Lyons, France, in 1822, under the name of the "Society for the Propagation of the Faith." The society gradually extended over nearly all countries of the globe. Its members pledge themselves to pay one sou a week. Its total receipts in 1859 amounted to 7,117,725 francs, and its expenditures to 4,561,539 francs. It publishes a bi-monthly periodical, the "Annals of the Propagation of the Faith," of which 204,950 copies are issued in the French, German, English, Italian, Spanish, Portuguese, Dutch, Flemish, and Polish languages. The society contributes to the support of all Roman Catholic missions. An important auxiliary to this society is the "Association of the Holy Childhood of Jesus," a children's missionary society, for baptizing and rescuing pagan children of China, and, if possible, for providing a Christian education for them. Its annual receipts amount to about 1,000,000 francs. The Leopoldine association in Austria, and the Louis association of Bavaria, support almost exclusively missions among the German emigrants in North America. The St. Mary's association of Austria was established for the sole support of the Austrian missions in Khartoum. France has special associations for the support of the missions in western Africa, for the foundation of Christian schools in Turkish Asia, and for missions among the Mohammedans.—The principal Roman Catholic missionary fields in pagan countries at present are: China, with one bishopric in the Portuguese possessions, 21 vicariates apostolic, 3 prefectures apostolic, and a native Catholic population estimated at 337,000 souls; India and Ceylon, which have, beside one archbishop at Goa and 8 bishops for the Portuguese possessions, 20 vicars apostolic, and a population of 1,033,000 souls, of which only a very small portion are English, Irish, French, and Portuguese Catholics, the others being natives; Indo-China, with 10 vicars apostolic (2 in Siam, 8 in Cochinchina, 1 in Cambodia, and 4 in Tonquin), and a population amounting at the outbreak of the new persecution in Cochinchina to 20,000 native Roman Catholics. The Roman Catholic population of Africa live mostly in the Portuguese, French, English, and Spanish pos-

sessions. The most important missions among the pagans are carried on in and near the French possessions in Senegambia, in Natal, and in the country of the Gallas in central Africa. In Polynesia there are 7 vicariates apostolic for the native population. New Zealand is reported to have 15,000 native Roman Catholics, and the Sandwich islands 22,000. The membership of the church among the Indians of North America amounts to several thousands, and is constantly increasing. For more information on the history of the Roman Catholic missions, see Wittmann, *Die Herrlichkeit der Kirche in ihren Missionen* (Augsburg, 1841); Hahn, *Geschichte der Katholischen Missionen* (Cologne, 1857 et seq.). A rich source of information are the *Lettres édifiantes*, extending from 1717 to 1774, and from 1780 to 1787, and the *Annales de la propagation de la foi* since 1822.—PROTESTANT MISSIONS. The principal reason why the Protestant churches did not engage extensively in foreign missionary enterprises during the first period of their existence, must be sought in their precarious position at home, and their struggles against powers which for a long time refused to acknowledge their legal existence. Yet the founders, the divines and the princes of the reformed churches, were by no means unconscious of the missionary duties of the church. Luther took frequent opportunity to remind the Christians of the "misery of pagans and Turks," and to exhort to prayers for them, and to the sending out of preachers. Like him all the prominent theologians of his times speak of the duty of the church to preach the gospel to the unbelieving. The earliest attempt at a Protestant foreign mission was made in 1555. A knight of Malta, Villegagnon, began, under the patronage of Henry II. of France, the formation of a French colony in Brazil, and, on the promise that the reformed religion should be taught there, 14 spiritual teachers were furnished by Calvin. On landing in 1556, they immediately set themselves to work in the organization of the future church, but their efforts were soon arrested, as Villegagnon demanded and obtained their return to France. Some evangelical princes showed a great interest in the cause. Gustavus Vasa of Sweden (1523-'60), in whose dominions paganism still existed among the Lapps, founded a mission among them, which was vigorously supported by some of his successors, especially by Charles IX. (1602-'11). Many of the German princes, as Duke Christopher of Würtemberg and Duke Ernest the Pious of Saxe-Gotha, made great efforts to awaken an interest in the missionary cause. In 1664 a German baron, Ernest von Wels, published two pamphlets in order to awaken a greater interest in foreign missions, and proposed the formation of a "Jesus Association" for the propagation of Christianity among the pagans. But few German theologians supported him, and the majority called him a fanatic and heretic. Wels then went to Holland, to be there ordained as a minister, and

then set out as a missionary to Surinam, where he soon fell a victim to his zealous labors. About this time three Protestant nations, the Dutch, English, and Danes, began to wrest from the Spaniards and Portuguese many of their transmarine possessions, and thus to open to Protestant missionaries a vast field of labor. The Dutch founded a number of colonies on the Molucca islands, Ceylon, and Sumatra, and displayed a great zeal in gaining the natives for the Reformed church. The motives and means of these missionary efforts were not always pure; thus, the governor of Ceylon declared that only those natives would get any kind of employment from the government who would sign the Helvetic confession. This declaration induced thousands to demand baptism, which was generally refused to none who were able to recite the Lord's Prayer and the Ten Commandments. At the close of the 17th century about 800,000 Cingalese had been baptized. There were, however, many devoted missionaries, who earnestly labored to spread a spiritual Christianity. The learned Walæus of Leyden advocated the formation of a missionary seminary, and the Dutch East India company cordially approved of the scheme, the execution of which proved eminently useful to the cause of reformed religion.—The settlement of New England by a company of nonconformists (1620) was soon followed by the arrival of John Eliot, who became deeply interested in the religious condition of the North American Indians. In 1646, after mastering the language, he formally entered upon a mission, with the Mohegan version of the Bible as the fruit of his own unaided labors. Among those who assisted him were John Cotton and the Mayhews. The short career of Thomas Mayhew, the first missionary of this family, was rewarded by the sight of nearly 800 Indian converts. Five successive generations of the Mayhews continued these labors in behalf of the Indians. In 1674 the Indians of the district were about 8,000, half of whom professed Christianity; but in 1792 they had decreased to 440.—A vast scheme of uniting all the Protestant churches of the world into one great missionary society was conceived by Cromwell. He intended to establish a Protestant college for the defence and propagation of the evangelical faith, which was to consist of 7 directors and 4 secretaries, and to receive from the state a fixed annual support. The whole earth was divided into 4 missionary provinces, each of which was to have its representative in the college. Though this scheme was not carried through, it prepared the English nation for an active support of the missionary societies which soon after sprang into existence. The formation of the first great missionary society of the Protestant world took place at the beginning of the 18th century. Some members of a "Society for promoting Christian Knowledge," which had been founded in 1698, constituted themselves in 1701 a committee for sending missionaries to the pagans. They assumed the name

of "Society for the Propagation of the Gospel in Foreign Parts," and the new association was sanctioned by William III. The original design was the formation of colonial churches, and mostly for this purpose the operations have been extended to the East and West Indies, southern Africa, the Seychelles, Australia, Tasmania, and New Zealand. An interesting circumstance in connection with this society is, that in 1735 John Wesley went to Georgia as its pioneer missionary. In 1859 it had 414 ordained missionaries, and 700 other agents paid and unpaid. Its gross income was reported at the anniversary of 1860 as amounting to £115,490. It is under the control of the Church of England, and the influence of the "high church" school at present prevails in its management. The "Scottish Society for propagating Christian Knowledge," founded in 1709, labored for some years among the North American Indians, but without permanent success.—Denmark, though it had begun in 1620 to found colonies in the East and West Indies, made no missionary exertions in behalf of the pagans until the reign of Frederic IV., who in 1711 established an annual appropriation of 2,000 rix dollars for missionary purposes, and organized in 1714 the royal college of missions. Unable to find the proper persons for foreign missions in Denmark, the government entered into arrangements with A. H. Francke, who furnished the first men, Ziegenbalg and Plutschow, for establishing a mission in Tranquebar. The society afterward extended their Indian missions considerably, though Denmark took very little interest in them. Most of the missionaries, among whom Christian Frederic Schwartz shone forth as a model, came from Germany, and the expenses for the missions in the territory of the East India company were mostly defrayed by the London society for promoting Christian knowledge. In 1835 the chief missions of the body were transferred to the society for the propagation of the gospel; and in 1844, when the last Danish possessions were transferred to Great Britain, the labors of the college of missions in India ceased altogether. The impulse given by King Frederic to the missionary cause called into existence two other remarkable enterprises. The one was a mission in Greenland, commenced in 1731 by a Norwegian pastor, Hans Egede; the other a new mission to Lapland, undertaken by the Norwegian Thomas von Westen. Both were conducted with great zeal and self-sacrifice. Egede induced the king to establish at Copenhagen a seminary, which trained catechists and missionaries for the Greenlanders, until the mission was wholly committed to the Moravians. It was at Copenhagen also that Count Zinzendorf received the first inspiration for the spread of the gospel. On his return to Herrnhut the Moravians engaged at once in the cause with a zeal unprecedented in the history of Protestantism. The support of foreign missions was for the first time officially declared to be a duty

of the entire church, and an official board intrusted with taking charge of it. The guiding principles of the Moravians were to await a special call from God before going to any part of the pagan world, to avoid as much as possible selecting missionary fields preoccupied by others, and to give the preference to those countries which were among the most abandoned, difficult, and miserable. All the missionaries gained a part or the whole of their support by mechanical or agricultural labor; and the congregations of natives, which were all organized after the model of the church at home, were likewise bound to contribute for missionary purposes. Thus their enterprises stand forth as a great success. The fields which they occupied in succession were the Danish West India Islands (1732), Greenland (1738), North American Indians (1734), Surinam (1735), South Africa (1736, renewed in 1792), Jamaica (1754), Antigua (1756), Barbados (1765), Labrador (1770), St. Kitts (1775), Tobago (1790, renewed in 1827), the Mosquito coast (1848), Australia (1849), and Thibet (1853). Altogether they reported in 1859, 14 missions, 600 missionaries, 143 stations, and 74,187 converts.—There is a great gap in the history of Protestant missions from 1732 to 1792. No new society was formed, and no efforts were made for the propagation of Christianity except by the few agencies mentioned above. Toward the close of the 18th century many circumstances worked together to prepare the dawn of a new period. A general dissatisfaction with the results of the rationalistic intellectualism began to pervade the Protestant nations, and a powerful counter-current led thousands back to a belief in the supreme necessity of experimental religion and personal piety. At the same time, members of all denominations longed to find ways and means to work together in fraternal union, in spite of denominational differences, for the common cause of Christianity. Free religious associations, not confined to the member of one particular denomination, became favorite institutions. The first foreign missionary society which was born out of this movement was the Baptist missionary society of England, established in 1792. The effect which its example produced throughout Christendom is unparalleled in the history of the Christian church. England first, and soon after America, multiplied their societies, until hardly a single Protestant denomination remained unrepresented. With the increase of societies kept pace the increase of their receipts, of the missionaries sent out, and of the converts from paganism. In continental Europe the interest in the missionary cause developed more slowly, but has of late received a new impulse. Every Protestant country has expressed a desire to do its share, and efforts are beginning to be made in several countries to unite all the evangelical missionary societies, for the sake of greater efficiency, into a kind of confederation.—A survey of all the societies of the Protestant world will best be obtained,

if we give a brief account: 1, of the British societies; 2, of the American; and 3, of those of continental Europe. I. *Great Britain*. The "Baptist Missionary Society" was founded under the overwhelming impression made by a sermon of William Carey, Oct. 2, 1792. Carey himself went forth as the first English missionary to India (1793), where soon Serampore became the centre of successful and extensive operations. A controversy between the Serampore mission and the parent society brought on a separation lasting 10 years, during which the two societies acted independently, but it did not arrest the progress of the mission. The Bible was issued from the Serampore press in 27 different versions, and the school operations were singularly prosperous. Among the missionaries, Marshman and Ward were especially distinguished. Beside India, the West Indies, western Africa, and France received missionaries from the Baptist society. In the West Indies, the churches in Jamaica separated from the home society in 1842, and charged themselves with the maintenance of the mission. In western Africa, the missionaries were expelled in 1858 by the Spanish government from the island of Fernando Po, and their missions forcibly suppressed. In 1859 the society reported 36 principal stations, 59 ordained missionaries (including 7 assistant missionaries), 144 other agents paid and unpaid, 5,118 church members (among whom were 4,636 natives), 6,164 children in their schools, and an income of £26,513. The General or Arminian Baptists started a separate society in 1816. They commenced a mission at Orissa in India in 1822, and at Ningpo in China in 1845. In 1859 they reported 7 stations in India, with 333 members, 9 chapels, and a nominal Christian community of 548. Their income was about £3,500.—The "London Missionary Society" owed its origin to a spirited paper in the "Evangelical Magazine," advocating the formation of a missionary society on the broadest possible basis. An invitation for that purpose was signed by 18 Independent, 7 Presbyterian, 8 Wesleyan, and 3 Episcopal clergymen; and the constitutive assembly took place Sept. 22, 1795, in a chapel of the countess of Huntingdon. The islands of the Pacific were selected as the first missionary field, and 29 young men selected from the large number of those who had offered themselves. On March 4, 1797, the missionaries landed on Tahiti and opened the first mission of the London society. Soon the society occupied also China and the East Indies, where Morrison and Milne prepared a translation of the Bible into Chinese, the islands of the Indian archipelago and Mauritius, southern Africa, the West Indies, Guiana, and North America. Their most important stations are at present those in the South sea, where Williams gained by his successful labors the name of an apostle of the Indians; and in southern Africa, where Moffat and Livingstone have distinguished themselves. In 1859 the society had 183 principal stations,

19,781 communicants, 785 educational institutions, including day and boarding schools, 88,625 scholars, 153 missionaries, and about 700 native agents. The society still adheres to its original broad basis, avoiding all denominational differences in point of doctrine and church government; but the subsequent organization of separate missionary societies, on the part of most of the English denominations, has left the London society mostly in the hands of the Independents. The "Church Missionary Society" for Africa and the East was organized April 12, 1799, by a number of distinguished men belonging to the evangelical school of the established church, among whom were Charles Simeon, Wilberforce, and others. The progress during the first years was slow, and no missionaries could be found in England, but the society had for some time to employ exclusively Germans. The first mission on the W. coast of Africa was unsuccessful, in consequence of the deleterious climate and the plots of the slave traders; but in Sierra Leone the missionary labors after 1818 were very prosperous. In 1814 the society had stations in India and New Zealand, in 1822 in N. W. America (Rupert's Land), in 1826 in the West Indies, in 1844 in China, and in 1857 in a new mission on the banks of the Niger. In 1859 the number of ordained missionaries (including about 50 natives) was 228, of other assistants 2,140, of communicants 16,231, and of scholars 88,546. The president of the society must always be elected from among the members of parliament. Vice-presidents are, according to a resolution of 1841, all the bishops of the Anglican church. Since 1825 the society has owned a missionary institute at Islington, which has room for 50 students, and generally counts about 80. The low church party of the establishment has always had a decided control over this society; yet all its missionaries have to submit to episcopal ordination and to subscribe the 39 articles; even the Germans who are employed by the society are now no longer exempt from the latter condition.—The first missions of the Wesleyan Methodists were commenced in 1786, when Dr. Thomas Coke, with 8 other missionaries, went to the West Indies. After the death of Wesley, Coke remained at the head of the Wesleyan missions, and crossed the Atlantic for missionary purposes no fewer than 18 times. Within 20 years the number of Methodist missionaries in the West Indies and North America rose to 48. In 1818 Coke embarked with 5 companions for the East Indies, but died before that country was reached. His companions founded a mission in Ceylon, which soon spread to the mainland of India. As long as Coke lived, the administration of foreign missions lay almost exclusively in his hands; but after his death the necessity of a missionary society was felt, which was organized in 1814 at Leeds, and soon became one of the most efficient in the world. Its missions extended in 1859 over Germany, Spain, Ceylon, India, China, S. and W. Africa, and the West

Indies; and they counted 151 circuits, 225 missionaries, 8,987 agents, 68,406 members, 3,271 on trial, 42,788 scholars in Sunday schools, and 180,719 attendants on public worship.—Beside these larger missionary societies, there are a number of smaller ones, as the Welsh Calvinistic Methodist foreign missionary society (founded in 1840), the English Presbyterian church's foreign mission (1844), the Turkish missions aid society, and the New Connection Methodist foreign mission (commenced in China in 1839).—A "Scotch Missionary Society" was organized at Edinburgh in 1796, and it sent the first missionaries among the Tartars near the Black and Caspian seas. After the suppression of all the Protestant missions in those regions by the Russian government in 1838, the association directed its efforts to western Asia and the West Indies. More recently the society has confined its labors to Jamaica. The established church of Scotland rejected, at its general assembly of 1796, as a folly, a motion to send missionaries among the pagans; but in 1824 a similar motion was entertained and carried. It was not however till 1829 that its first missionary, Dr. Duff, was sent out to Calcutta. In 1843, when a large portion of the ministers and laity left the established church of Scotland, and organized the Free church, all the missionaries joined the latter. The missionary cause greatly gained by this separation, for the established church sent out new missionaries to carry on the work, and both churches henceforth tried to excel each other in zeal.—Among the other societies established by Great Britain and its colonies are: the Glasgow missionary society, in 1796; the Free Church of Scotland's foreign mission, 1843; the Glasgow African mission society, 1837; the Irish Presbyterian church's foreign mission, 1840; the Edinburgh medical missionary society, 1841; the Reformed Presbyterian church's foreign mission, 1842; the Loo-Choo naval mission, 1843; the Patagonian mission, 1844; the United Presbyterian church's foreign mission, 1847; the Chinese evangelization society, 1850; and the Chinese society for furthering the gospel, 1850. II. America. In the United States attention was early called to the necessity of missionary efforts among the Indians and negroes. The first foreign missionary society was founded under the name of the "American Board of Commissioners for Foreign Missions" in 1810. It owed its origin to a society of students of Andover theological seminary, among whom was Adoniram Judson, whose object was to investigate the best ways and means of making the gospel known to pagan nations. After the model of the London society, they adopted no denominational basis; but the society soon became prominently the organ of the Congregationalists and some of the Presbyterian churches. One of the latter, the Reformed Dutch church, separated a few years ago, and organized a denominational board of foreign missions, which sustains now 8 missions in China and India, and in 1859 sent out missionaries

ries to Japan. Its receipts in 1859 were \$25,184. The principal Presbyterian body still in connection with the American board is the New School Presbyterians; but they likewise took steps in 1859 for establishing a closer connection of the Presbyterian missionaries employed by the American board with the Presbyterian church, by the formation of foreign presbyteries. Among the missions of the board, that to the Armenians has been eminently successful, and has already resulted in establishing a native Protestant church in Turkey on a permanent basis. The other missions comprise India, China, S. and W. Africa, the Sandwich islands, and the North American Indians. The entire number of missions in 1859 was 26; of stations, 127, and of outstations, 181; ordained missionaries, 170; whole number of laborers connected with the missions, 896; printing establishments, 5; churches, 158; church members, 23,515; seminaries, 7; number of scholars in seminaries and schools, 8,892; receipts, \$350,915. Mills, Nott, Hall, Schauffler, Winslow, Dwight, Goodell, and others, have been among the distinguished missionaries of this society.—The “American Baptist Missionary Union” was founded in 1814. The principal field of its operations is Indo-China, where the missions among the Karens have excelled in rapidity of growth any other Protestant mission of the world. The Christianization of the whole nation is rapidly advancing, and already Karen missionaries are setting out for the conversion of neighboring tribes. The board in 1859 had under its care 19 missions, 14 of which were in southern Asia, 1 among North American Indians, and 2 in Europe. There were connected with the missions 13 American laborers and about 800 native helpers. The membership of the mission churches amounted to about 22,000, of which over 14,000 were in Asia.—The missionary society of the Methodist Episcopal church was started in 1819. The most numerous missions are in Germany and Liberia; but it has also established missions in China, India, South America, Scandinavia, Bulgaria, and the Sandwich islands. The number of the missionaries in 1859 was 47, and of members 8,743. About the same time (1820) the Protestant Episcopal church organized a board of missions, which employs about 100 laborers under two missionary bishops in W. Africa, China, Greece, Brazil, and Japan. The membership connected with the churches is about 400; the receipts in 1859 were \$99,476.—The board of foreign missions of the Presbyterian church, Old School, founded in 1837, is very active. It had been preceded by a number of smaller societies, some of which had confined their labors to the Indians. It commenced missions in Liberia in 1832, in India in 1833, in China in 1838, among the Chinese in California in 1852, and more recently has sent out missionaries to South America and Japan. Connected with its missions are 73 ordained ministers, 1,158 communicants, and 2,310 scholars.—The Evangelical Lutheran church has

sustained a mission in India since 1841, which in 1859 had 5 missionaries and 86 communicants. The Seventh Day Baptists instituted a foreign mission in 1842, the scenes of whose labors have been western Asia and China, with 8 agents. The southern Baptist foreign mission society, instituted in 1845, has missions in China and W. Africa; the Methodist Episcopal church, South, in China; the United Presbyterians, in western Asia, in Egypt, India, and the islands of the Pacific; the Freewill Baptists and the Unitarians in India. The Cumberland Presbyterians established their first foreign mission in 1860 in Turkey. Some missionary societies have branched off from older associations, on the ground of having no connection with slavery. Such are the “Baptist Free Missionary Society,” organized in 1843, with a mission in Hayti; and the “American Missionary Association,” formed in 1846, and soon joined by the West Indian mission, the western evangelical missionary association, and the Union missionary society, which at once gave to the new society laborers in the West Indies, among the North American Indians, and in W. Africa; its labors have since extended to Siam, the Sandwich islands, and the Copts in Egypt; its receipts in 1859 amounted to \$50,511, and the number of its foreign missionaries to 45. The American and foreign Christian union, established in 1849, directs its efforts mostly to sending out missionaries among the Roman Catholics of America and Europe; its receipts in 1859 were \$73,202.

III. *Continental Europe.* The continent of Europe has remained, in zeal for the missionary cause, far behind England and America. The first country which, at the close of the 18th century, followed the example of the English, was Holland, which formed in 1797, mainly through the influence of Dr. Vanderkemp, a Dutch missionary employed by the London missionary society, the “Netherlands Missionary Society,” at Rotterdam. The political events, in consequence of which Holland lost her colonies, caused a postponement of independent operations until 1819, when they commenced in the Indian archipelago, which is still their chief seat. The missions in India proper, when Holland exchanged with Britain these settlements, were transferred to English societies, but other missions were founded at Surinam, Guiana, and in Curaçoa in the West Indies. The society sustains a seminary at Rotterdam, and counted among its missionaries the celebrated Dr. Gützlaff.—The most extensive of the missionary societies of continental Europe is that of Basel. Unlike the others, it was preceded by the establishment of a missionary seminary, in 1815, which has furnished a number of devoted missionaries to other societies, especially English. An independent society, the “Evangelical Missionary Society of Basel,” was formed in 1821, which now sustains missionaries in North America, W. Africa, India, and China. The income rose, in 1859, from 800,000 to 622,000 francs, and

the entire missionary family, not including the native evangelists and teachers, numbers more than 200 persons; 70 students are under education, and from 30 to 40 children of missionaries are brought up in a separate establishment. The Basel society has received from its foundation the missionary contributions from a number of the German churches. Afterward several other societies sprang up, whose operations, however, have been thus far inferior to those of the English and American societies. Those exclusively or mainly Lutheran are the evangelical Lutheran missionary association of Leipsic, founded in 1836, and occupying in southern India the former missionary field of the Danes; the Berlin missionary society, instituted in 1824, and supporting a mission in S. Africa; and the Hermannsburg society, founded in 1854, which has adopted the plan of sending out entire missionary colonies. Those whose sympathies are with the evangelical party are the Rhenish missionary society, founded in 1828, Gossner's missionary union, in 1836, and the North German missionary society, in 1836, which have missions in Africa, India, China, the Indian archipelago, and the islands of the Pacific. Special associations for China have been formed in Cassel, Berlin, and Pomerania, mostly occasioned by the reports of Dr. Gützlaff; and it was intended to unite them all into a central Chinese missionary association, but this proved unsuccessful. Of late years, the aggregate receipts of the German missionary associations have rapidly risen, as the supreme authorities of nearly all the state churches have strongly recommended them and prescribed the taking up of an annual collection in every church.—France has had a missionary society since 1822, which sustains a flourishing mission in S. Africa, where it has now 13 stations, 14 missionaries, a large band of native assistants, and an income of £4,545.—The Scandinavians have been as yet hardly represented in the foreign missionary field. The Swedes have almost restricted themselves to sending preachers to the Laplanders, and only China has received a few missionaries from a society in Lund. The Norwegian missionary society, established in 1842, has some agents among the Zooloos in S. Africa. But in Scandinavia also, the activity of the missionary societies is increasing. Norway founded a foreign missionary seminary at Bergen in 1859; the second Scandinavian church diet recommended the formation of one great Scandinavian missionary society; and in Denmark, the union of all the local societies into a Danish missionary society was effected in June, 1860.—Having thus given a brief survey of the various missionary associations of the Protestant world, it remains to glance over the various missionary fields to see what has thus far been achieved. In Turkey and Persia, it is especially the Armenians and the smaller oriental denominations that have been penetrated with the principles of Protestantism. Numerous Protestant congregations have been organized among them,

a Protestant literature and periodical publications commenced, and seminaries, colleges, and schools opened. In Persia, Protestantism has exercised a powerful influence on the entire body of the Nestorians. The Greek church has offered to the Protestant missionaries a great resistance; yet among its members a number of missionary schools are in successful operation. Little success has as yet attended the missions among the Mohammedans; but within a few years some conversions to Christianity have taken place, the sale of Bibles and other Christian books has wonderfully increased, and an uncommon interest to become better acquainted with the peculiar doctrines of Christianity has been manifested. In India and Indo-China large accessions to the number of Christians have recently taken place. Indo-China will soon have at least one entirely Christian tribe, the Karens. China has flourishing Protestant communities in Hong Kong and in the five cities with their environs, which are open to European trade. The membership and influence of these congregations are rapidly increasing, and promise great and speedy success. Japan has been occupied since 1859 by a number of missionaries, but the laws do not as yet allow the conversion of natives. In the Indian archipelago, several islands, especially those owned by the Dutch, have been to some extent brought under the influence of Protestant Christianity. In Africa efforts were made as early as 1752 to evangelize the Copts; the church missionary society founded in 1832 a Coptic school, and in 1838 a seminary for Coptic priests. The influence of the society on the Coptic church has, however, of late decreased; but in Abyssinia the king Theodorus has promised to the missionaries his active coöperation for a Protestant reformation of the church. In Madagascar the introduction of Christianity was patronized by the young and powerful king Radama, who had subjected to himself four fifths of the island; but after his death in 1828 his widow arrested the progress of Christianity by cruel persecution, though it was found impossible to extirpate it. The tribes of southern Africa, which are divided into three principal classes, the Hottentots, Bechuanaas, and Caffres, received the first preaching of Christianity through Moravian missions in 1787, which are still flourishing both among the Hottentots and the Caffres. The missions of the London missionary society spread from the Cape Colony in all directions and centred principally among the Bechuanaas, where especially Moffat distinguished himself. More recently the travels of Livingstone and the efforts of the colonial government of the Cape have greatly increased the prospects of completing the Christianization of S. Africa. In W. Africa the Christianization of the natives, the negroes, is making rapid progress; there also the Moravians were the pioneer missionaries in 1787. The English colony of Sierra Leone (since 1787) and the negro republic of Liberia (since 1822) have come fully under the direct

on of Christianity, and are nurseries for native missionaries in the interior of Africa. In the north of America, the Esquimaux of Greenland who live in the dominions of Denmark have been almost completely Christianized. Among those on the coast of Labrador the Moravians have 4 stations with numerous congregations, and they have of late made explorations to establish new gathering places for the poor Indians. The vast area of Hudsonia, or Rupert's Land, though since 1670 under the sway of the Hudson's Bay company, was not opened to Christian missions until 1822, since which time several thousand Christian Indians have been collected into colonies, under the auspices of the church of England. The missionary labors among the Indians in the territory which now constitutes the United States commenced early in the 17th century with Eliot and the Mayhews, and has since engaged the earnest attention of most of the American denominations; yet the majority of the Indians are still pagans, and the number of church members does not amount to more than 12,000. The negro population, on the other hand, is completely under the influence of the Christian church, and comprises at present a church membership of about 500,000. The native population of the West Indies has been fully Christianized, owing especially to the missions of the Moravians, Wesleyans, and Baptists. In the Dutch and English possessions in Guiana the greatest sacrifices of the missionaries have only succeeded in firmly establishing some advanced posts against the paganism of the interior. Australia and Polynesia, in which the mission among the natives was commenced by the London missionary society in 1795, have since been almost wholly converted to Christianity. While the Australian continent has been colonized by Europeans, the islands, and in particular Tahiti, the Feejee and the Sandwich islands, have become Christian states, owing in particular to the American board and the English Wesleyan society. The former in 1859 had 20,231, and the latter 15,186 communicants connected with the native congregations. A number of special missionary societies have been organized for the Christianization of the Jews. These societies together employ about 100 missionaries, and reckon 20,000 converts since the beginning of the 19th century. An observation of the increasing missionary agencies on the one hand, and of the great decline of external hindrances on the other, leaves no doubt that the prospects of the Protestant foreign missions are at present brighter than at any former epoch of church history, and that the formation of a number of new Christian tribes and nations is rapidly approaching.—The literature on the history of the Protestant missions is very copious. Almost every missionary society publishes a periodical, which, together with the annual reports of the societies, is the most trustworthy source of information for the missionary history of a particular denomination or society. The number of works published by

missionaries on special countries is likewise very large. Among the works extending over the whole ground are: W. Brown, "History of the Propagation of Christianity among the Heathen since the Reformation" (2 vols., London, 1814); Huie, "History of Christian Missions from the Reformation to the Present Time" (Edinburgh, 1849); Wiggers, *Geschichte der evangelischen Missionen* (2 vols., 1845-'46); *Handbüchlein der Missions-Geschichte und Missions-Geographie* (Calw, 1844); Newcomb, "Cyclopædia of Missions" (New York, 1860); Aikman, "Cyclopædia of Christian Missions" (London, 1860). A list of all the Protestant missionary societies, together with the statistics of the missionaries, churches, membership, receipts, publications, &c., and a tabular view of the several missionary fields, are given in Schem's "Ecclesiastical Year Book" for 1859 (New York, 1860).

MISSISSIPPI, one of the S. W. states of the American Union, and the 7th admitted under the federal constitution, situated between lat. 30° 18' and 35° N., and long. 88° 7' and 91° 41' W.; extreme length N. and S., 332 m.; average breadth 142 m., varying from 78 m. below lat. 31° N. to 189 m. on that parallel, and 118 m. on the N. line; area, 47,156 sq. m., or 80,179,840 acres, being 1.61 per cent. of the territorial extent of the United States. It is bounded N. by Tennessee; E. by Alabama; S. between the Alabama line and Pearl river by the gulf of Mexico, and from the Pearl to the Mississippi on the parallel of 31° N. by the state of Louisiana; and W. by Louisiana and Arkansas, having below lat. 31° N. the Pearl river, and above that line the Mississippi, as the dividing lines. The Round, Horn, Ship, Deer, Oat, Poia, and several other islands lying outside of and forming the S. limit of the Mississippi sound, belong to this state. The state is divided into 60 counties, viz.: in the northern district, Attala, Bolivar, Calhoun, Carroll, Chickasaw, Choctaw, Coahoma, De Soto, Itawamba, Lafayette, Lowndes, Marshall, Monroe, Noxubee, Oktibbeha, Panola, Pontotoc, Sunflower, Tallahatchie, Tippah, Tishomingo, Tunica, Winston, Yallobusha; and in the southern district, Adams, Amite, Claiborne, Clark, Copiah, Covington, Franklin, Greene, Hancock, Harrison, Hinds, Holmes, Issaquena, Jackson, Jasper, Jefferson, Jones, Kemper, Lauderdale, Lawrence, Leake, Madison, Marion, Neshoba, Newton, Perry, Pike, Rankin, Scott, Simpson, Smith, Warren, Washington, Wayne, Wilkinson, Yazoo. The principal cities and towns are Jackson, the capital, Natchez, Vicksburg, Port Gibson, Biloxi, Mississippi City, Pascagoula, Pass Christian, Handsborough, Paulding, Brookhaven, Summit, Magnolia, Corinth, Grenada, Grand Gulf, Yazoo City, Shieldsborough, Aberdeen, Brandon, Canton, Columbus, Holly Springs, Macon, Oxford, and Woodville.—The population of Mississippi, according to the enumerations made decennially, has been as follows:

Years	White persons.	Colored persons.		Total population.	Increase per cent.
		Free.	Slave.		
1800.....	5,179	182	2,499	8,850
1810.....	23,024	240	17,088	40,352	855.96
1820.....	42,176	458	32,814	75,448	86.97
1830.....	70,448	519	65,659	136,621	81.08
1840.....	179,074	1,866	195,211	375,651	174.96
1850.....	295,718	980	309,878	606,826	61.46

Of the total white population in 1850 (48.76 per cent. of the whole), 156,287 were males, and 139,431 females; of the free colored persons (.015 per cent.), 295 were blacks and 685 mulattoes, and 474 males and 456 females; and of the slaves (51.09 per cent.), 290,148 were blacks and 19,730 mulattoes, and 154,964 males and 154,914 females. Ages: under 1 year, 16,086; 1 and under 5 years, 88,975; 5 and under 10, 94,355; 10 and under 15, 81,780; 15 and under 20, 65,784; 20 and under 30, 110,890; 30 and under 40, 70,927; 40 and under 50, 40,159; 50 and under 60, 20,717; 60 and under 70, 11,121; 70 and under 80, 3,406; 80 and under 90, 994 (slaves 581); 90 and under 100, 288 (slaves 170); 100 and upward, 140 (slaves 120); unknown, 954. Deaf and dumb, 107; blind, 205; insane, 129; idiotic, 222. The white and free colored population (296,648) occupied 51,681 dwellings, and constituted 52,107 families. In the year 1849-'50 there were born 8,687 (2.98 per cent.), married 2,774 (0.93 per cent.), and died 3,874 (1.14 per cent.). The total deaths in the year, including slaves, were 8,721, or 1.44 per cent. of the total population. Of the white and free colored population in 1850 there were born in the United States 291,852, in foreign countries 4,788, and in places not ascertained 506. Of those born in the United States, 140,885 were natives of Mississippi, 34,047 of Alabama, 27,908 of South Carolina, 27,439 of Tennessee, 21,487 of North Carolina, 17,506 of Georgia, 8,857 of Virginia, 3,948 of Kentucky, and 2,557 of Louisiana; and of the foreigners, 2,848 were born in Great Britain and Ireland, 1,151 in Germany, 440 in France, 121 in Italy, and 79 in British America. The employments of the free male population over 15 years of age (75,082) were as follows: in commerce, trade, manufactures, and mechanic arts, 12,053; in agriculture, 50,284; in labor not agricultural, 6,067; in sea and river navigation, 292; in law, medicine, and divinity, 2,829; in other pursuits requiring education, 3,880; in government civil service, 377; in domestic service, 69; and in other occupations, 231. The number employed in manufacturing establishments in 1820 was 650; in 1840, 4,151; and in 1850, 8,178. The number of slaveholders in 1850 was 23,116, viz.: holders of 1 slave, 8,640; of 1 and under 5, 6,228; of 5 and under 10, 5,143; of 10 and under 20, 4,015; of 20 and under 50, 2,964; of 50 and under 100, 910; of 100 and under 200, 189; of 200 and under 300, 18; of 300 and under 500, 8; and of 500 and under 1,000, 1. The federal representative population (all the free and $\frac{3}{4}$ of the slave) was 482,574, and entitled the state to 5 mem-

bers of the house of representatives.—Mississippi has in general an undulating surface, with a general slope toward the S. W. and S. The coast has a shore line on the gulf of Mexico of 88 m., or including the irregularities and islands of 287 m., but has no harbors that admit large vessels. Those of Mississippi City, Shieldsborough, and Biloxi, constituting Ship Island harbor, are the best; and the whole are included in the collection district of Pearl River. About 6 or 8 m. from the shore is a chain of low sandy islands, which form the bay of St. Louis on the west, and Pascagoula, now commonly called Mississippi sound, on the east. These islands produce nothing but pines and coarse grass, and are of but little commercial value, except Ship island, which has a good harbor, and may in the future become a station for ocean steamers. The shores near the mouths of the Pascagoula and Pearl rivers are also low and sandy, and in many places interspersed with marshes. The Mississippi sea coast or shore is for the most part sandy, but productive, elevated above the highest tides, and covered almost to the water's edge with a dense growth of live oak, and magnolia. Where the Pearl and Pascagoula debouche into the sound there are extensive marshes, most of which, it is believed, are susceptible of reclamation. The intervening country, irrigated by numerous tide water streams, is level but dry, producing luxuriant pasturage and a colossal growth of yellow pine. It is one of the healthiest districts in the world. The tract contiguous to the Mississippi river consists of numerous hills very irregularly scattered over the surface, and rising from 50 to 150 feet above the narrow low tract which in some places lines the course of the river. The hills, the base of which is washed by the Mississippi, are called "bluffs," and this region is generally called by this name. It extends from 10 to 25 m. inland, and is of great fertility, being covered with forests of oak, gum, poplar, ash, maple, and hickory, and a few pine trees. Further E. the country rises imperceptibly higher and extends in wide plains. The numerous water courses which occur on these plains have furrowed their outer edges along the Mississippi, and imparted to them a level aspect together with a great degree of fertility. The plains themselves are sandy and covered with the long-leaved pine; but their continuity is interrupted by the bottoms which extend along the affluents of the lower Mississippi, the Pearl, and the Pascagoula, which are several feet lower than the general surface, and from 1 m. to 3 m. wide. These bottoms have a rich and productive soil covered with a fine growth of trees, intermingled in the more elevated parts with lofty canes. The lower parts are mostly cypress swamps. The "bluff" region continues N. to the mouth of the Yazoo, and the furrowed pine plains somewhat further, where they become intersected by rolling prairies, which increase in number and extent further N. and occupy the greatest portion of the country lying

N. of lat. 33°. These prairies where uncultivated are covered with grass during the greatest part of the year, though the country is dry and suffers from want of water. East of this prairie region extends a level but very fertile tract on the upper course of the Tombigbee, which resembles the bottoms in fertility, but is more extensive. In the N. district is a range of hills of moderate elevation, well wooded but devoid of undergrowth, terminating on the Mississippi with what is called the fourth Chickasaw bluff, which extends 10 m. along the river, and is from 60 to 100 feet above its bank. Between these hills and the Walnut hills, with which the southern bluffs terminate in about lat. 32° 30', a distance of more than 170 m., the country is occupied by an immense swamp, produced and fed by the inundations of the Mississippi. Some parts of this low region become dry toward the end of the year, but the others are a permanent swamp. This tract extends to the edges of the prairie region, embracing the Yazoo valley, and is in its widest part (near lat. 34°) about 50 m. wide. As a cultivable country it has no superior, and when drained will be capable of supplying vast amounts of cotton, Indian corn, and other southern staples.—This state, with the exception of the N. E. corner through which the Tennessee river runs, is drained either directly or through the Mississippi river into the Gulf of Mexico. The Mississippi forms its W. boundary for more than 500 m. by its windings; but for more than three fourths of this distance, from the N. limit of the state to Vicksburg, the configuration of its banks admits of no port, and below that city the only one of much importance is Natchez. The principal affluents of the Mississippi from this state are the Homochitto, the Big Black, and the Yazoo rivers. The principal constituents of the Yazoo are the Tallobusha and Tallahatchee; and not far from its mouth it receives the Sunflower, that branch of the Mississippi which leaves the main stream S. of the fourth Chickasaw bluff and traverses the great alluvial swamp. Bayou Pierre is another affluent of the Mississippi from this state, and disembogues a few miles below the mouth of the Black river. Pearl and Pascagoula rivers are the most important flowing to the gulf. The Pascagoula, which waters the S. E. part of the state, is formed by the junction of the Chickasawha and Leaf rivers, and near its mouth is joined by a tributary, the Escatawpa or Dog river, from Alabama. There are many other streams in all parts of this state, which, though inferior in capacity to those already noticed, are locally important, watering extensive districts and giving fertility to the soil. Nearly all parts indeed are abundantly supplied with running streams.—The state of Mississippi is occupied wholly by deposits of the tertiary and upper secondary formations, which, sweeping around from the southern Atlantic states, attain here their greatest width. Near the gulf of Mexico the sands and clays of the latest periods are spread over the country, and further N. the de-

posits gradually become of greater age. At Vicksburg the eocene appears at the base of the river bluffs, and the upper portion of these is covered by a deep deposit of yellowish loam or loess, containing fresh water and land shells. This extends over the country eastward, and attains a thickness of 60 feet or more. The upper secondary appears near Jackson, and occupies the northern portion of the state. From these formations the only mineral productions the state can furnish are of agricultural interest. The fertility of the soil and a favorable climate give to Mississippi eminent advantages as an agricultural state. There is perhaps no other country in the world that has such alluvial lands as the Mississippi bottom contains—an alluvial plain in a mild climate, level as the surface of the ocean and of inexhaustible fertility; and this plain is only a small part of the fertile lands of the state. The table lands of the north, the loams along the bluffs and banks of the Mississippi, the dark and heavy prairie lands, and the inland bottoms are of scarcely less fertility. The prairies, especially in the Tombigbee district, furnish excellent pasturage. The climate is remarkably equable. Sugar is produced in the south, and cotton forms the great staple of a large part of the state. Wheat and other grains occupy the northern districts. All the fruits of temperate climates grow here in perfection; plums, peaches, and figs are abundant, and in the south the orange. Wild animals, such as the deer, puma, wolf, bear, and wild cat, are still common. Alligators occur in the Mississippi as far N. as the mouth of the Arkansas, and in some of the smaller rivers; and most of the streams abound in fish. Paroquets are seen as far N. as Natchez, and wild turkeys and pigeons abound.—In 1850 Mississippi contained 83,960 farms and plantations, of which 15,110 cultivated cotton to the amount of 5 bales and upward. The total quantity of land in these was 10,490,419 acres, of which 8,444,358 were improved. The cash value of the whole was \$54,738,634; and the value of implements and machinery thereon was \$5,762,927. The live stock owned in the same year consisted of 115,460 horses, 54,547 asses and mules, 214,231 milch cows, 83,485 working oxen, 436,254 other cattle, 304,929 sheep, and 1,582,734 swine, in all valued at \$19,403,662; and the value of animals slaughtered in 1849-'50 was \$3,636,582. The cotton crop amounted to 484,292 bales of 400 lbs. each. The grain crops consisted of 137,990 bushels of wheat, 9,606 of rye, 1,503,288 of oats, 22,446,552 of Indian corn, 228 of barley, 1,121 of buckwheat, and 261,482 of Irish and 4,741,795 of sweet potatoes. The other agricultural products were: hay, 12,504 tons; hops, 473 lbs.; clover seed 84, and other grass seed 538 bushels; peas and beans, 1,072,757 bushels; beeswax and honey, 397,460 lbs.; flaxseed, 26 bushels; flax, 665 lbs.; dew-rotted hemp, 7 tons; cane sugar, 8,000 lbs.; molasses, 18,818 galls.; tobacco,

49,960 lbs.; silk cocoons, 2 lbs.; wine, 407 galls. The value of market garden products was \$46,250, and of orchard products \$50,405. Home-made manufactures were produced to the value of \$1,164,020. The average production to the acre of wheat was 9 bushels, Indian corn 18, oats 12, peas and beans 12, Irish potatoes 105, and of seed cotton 650 lbs. The ratio of the cotton crop to that of the whole country was 19.8 per cent. The total value of the products of agriculture in 1849-'50 was \$36,802,141; in 1840 it was \$26,297,666.—The value of the productions of manufactures and the mechanic arts in 1840 was \$2,879,425, and in 1850, \$2,972,088. In 1850 the total number of establishments was 877, employing a capital of \$1,838,420, and 3,173 hands, viz., 3,065 males and 108 females, using raw material to the value of \$1,290,271, and paying annually in wages \$775,128. Of these, 2 were cotton mills (capital \$38,000) and 8 cast iron works (capital \$100,000). The remainder consisted of mills of various descriptions, tanneries, and mechanic shops, such as are necessary to agricultural states.—Mississippi has but a small share of direct foreign commerce, and in many years none is recorded in the published returns. Its foreign trade is indirect, and almost entirely through New Orleans and Mobile. Cotton and lumber are the chief exports. The amount of shipping held in the state in 1850 was 1,828 (steam 675) tons, and in 1859, 2,690 (steam 676) tons, all of the class "enrolled and licensed," and engaged in the coasting trade. The coasting and river trade is necessarily great, and employs a large tonnage. The coasting trade is chiefly directed to Mobile and New Orleans, while the Mississippi river trade centres in the latter, and that of the Tombigbee in Mobile. The railroads terminating at these two ports are also large carriers of merchandise to and fro, and have tended largely to develop the material interests of the state. The following table shows the extent of the completed portion of the Mississippi system and its cost to the end of 1859:

Railroads.	Miles.	Cost.
Grand Gulf and Port Gibson.....	8	\$300,000
Memphis and Charleston (part).....	27	800,000
Mississippi Central.....	187	4,500,000
Mississippi and Tennessee.....	60	1,600,000
Mobile and Ohio.....	170	4,000,000
Columbus branch.....	14	
N. Orleans, Jackson, and Great Northern	118	2,500,000
Raymond branch.....	7	90,000
Southern Mississippi.....	68	2,500,000
West Feliciana (part).....	19	850,000
Total.....	713	\$17,570,000

The uncompleted portion of the system has an equal length of line. The New Orleans, Jackson, and great northern, and the central, form a great N. and S. line through the middle of the state, and the Mobile and Ohio runs in the same direction near the E. boundary, the two lines connecting the systems from the lake and upper Mississippi regions with the southern ports of New Orleans and Mobile; and the Mississippi and Tennessee, branching from the central at Grenada, extends

to Memphis. The Memphis and Charleston crosses the N. E. part of the state transversely. the southern crosses its middle and a line still to be built will cross it near the gulf coast. These will form links in the great chains which will eventually connect the Atlantic and Pacific coasts. The other roads named in the above table are local, but of great advantage to commerce. The length of post route in the state in 1858 was 8,802 m., of which 867 m. was railroad, 677 m. steam navigation, 1,075 m. coast road, and 1,683 m. other road. The telegraph connects the chief places within the state, and the state with all the principal points of the Union.—On Jan. 1, 1860, Mississippi had 3 banks, the condition of which was as follows: Liabilities: capital, \$1,110,600; circulars, \$318; deposits, \$49,875; profits on hand, \$15,821. Resources: notes, bills of exchange, &c., \$394,756; specie, \$591; real estate, \$780,767; total, \$1,176,114.—The government is based on the constitution of 1817 and amendments thereto. The right to vote is enjoyed by every free white male person, 21 years of age, who is a citizen of the United States and has resided in the state for one year and in the town or county for 4 months next preceding an election. The general election is held on the 1st Monday in October, and the legislature meets on the 1st Monday in November biennially (odd years). The senate is composed of 32 members elected for 4 years, and the house of representatives of 92 members elected for 2 years. The governor, who must have been a citizen of the United States for 20 years and a resident of the state for 5 years, is elected for 2 years, and has a salary of \$4,000. The principal administrative officers are the secretary of state (salary \$1,200), the state treasurer (\$1,800), the auditor of public accounts (\$1,500), &c. The judiciary consists of a high court of errors and appeals, circuit courts, justices of the peace, and probate courts. The high court is composed of 3 judges (salary \$3,000), elected from districts, the attorney-general (\$1,200), a clerk (fees), and a reporter; the last is elected by the legislature. The circuit court has original jurisdiction in civil cases in which the sum in controversy exceeds \$50, and exclusive jurisdiction in criminal cases. In each of the circuits, 10 in number, a judge and attorney are elected every 4 years. Each county has a probate court with a judge and a clerk. The probate clerk is also register of deeds. All judicial officers are elected by the people. The revenues of the state are derived chiefly from taxation. For the year ending Aug. 30, 1850, the income from all sources amounted to \$379,402, and the expenditures to \$254,999; for the year ending Oct. 31, 1859, the receipts from all sources were \$632,952, and the expenditures \$614,659. The absolute debt of the state in 1857 amounted to \$2,271,707, and the total debt to \$7,271,707. The annual interest payable on the absolute debt was \$120,000. Against this debt the state owns about \$2,000,000 of unproductive property. The va-

nation of taxable property in 1850 was \$208,122,167, and in 1857 \$462,656,736. Included in 1857 were 368,182 taxable slaves, valued at \$220,990,000. The institutions supported wholly or in part by the state are an asylum for the blind, one for the deaf and dumb, and a lunatic asylum, all at Jackson; also at the same place the state penitentiary, in which were confined on Oct. 31, 1857, 105 convicts, of whom 85 had been admitted during the year. Paupers supported in whole or part within the year ending June 1, 1850, 260, of whom 257 were receiving support at that period; cost yearly, \$18,182. On June 1, 1850, there were in prison 46 convicts, and during the year then ending 51 criminals had been convicted.—There is no uniform common school system. Each township has a school fund, arising from the congressional grant of every 36th section, and there is a distribution from the county fund arising from fines, forfeitures, licenses, &c., to destitute towns. In all the larger towns public schools have been established, and there are also many flourishing high schools. The total number attending school in 1849-'50 was 48,808, or 1 in every 6.06 of the white or in every 12.4 of the total population. Free colored persons are not admitted into the schools. The school statistics for June 1, 1850, as shown by the census of that year, were as follows: 782 primary and public schools, with 126 teachers, 18,746 scholars, and an annual income of \$254,159; 171 academies and private schools, with 297 teachers, 6,628 scholars, and an income of \$26,286; and 11 universities and colleges, with 45 teachers, 862 students, and an income of \$42,400; making a total of 964 schools, 1,168 teachers, 26,236 scholars, and an income of \$322,795. The number of white and free colored persons over 20 years of age who could not read and write was 13,528. The principal collegiate institutions in the state are: Oakland college, Claiborne co., founded in 1830; the university of Mississippi, at Oxford, 1844; Mississippi college, at Clinton, 1851; Madison college, at Sharon, 1852; the law department of the university at Oxford, 1853.—The most numerous religious denominations are the Methodist, Baptist, and Presbyterian. In 1850 the total number of churches in the state was 1,016, with accommodations for 294,104 persons, and as property valued at \$755,542. Of the churches, 885 belonged to the Baptist denomination, 8 to the Christian, 13 to the Episcopal, 454 to the Methodist, 143 to the Presbyterian, and 9 to the Roman Catholic; and 8 were free churches, and 1 union. The total number of newspapers and periodicals published in 1850 was 50, circulating annually 1,752,504 copies; of these, 4 (245,440 copies) were issued bi-weekly, and 46 (1,507,064 copies) weekly; and 10 (circulating 283,480 copies) were literary and miscellaneous, and 40 (1,519,024 copies) political. In the same year there were in the state 117 libraries other than private, and these contained 21,787 volumes; 4 were public libra-

ries with 7,264 vols., 103 school libraries with 3,650 vols., 6 Sunday school libraries with 780 vols., and 4 college libraries with 10,098 vols.—De Soto and his companions were the first Europeans that traversed this region. They made no settlements, however, and the death of the leader in 1542 put an end to the expedition. In 1682 La Salle descended the Mississippi, took formal possession of the adjacent country for the king of France, and called it Louisiana. In 1698 M. d'Iberville was authorized by the French king to colonize the regions of the lower Mississippi. He landed near Ship island, and from this point, setting out with two large barges, he explored the coast, discovered the mouth of the Mississippi, reached the bend at the mouth of Red river, and returning to Ship island erected a fort at the bay of Biloxi, about 80 m. E. from the site of New Orleans. He then embarked for France, leaving the fort in command of his two brothers Sauvolle and Bienville. In Dec. 1699, Iberville returned, and soon after built a fort on the banks of the Mississippi. In 1700 the chevalier de Tonty arrived at Iberville's fort with a party of Canadian French from Illinois. Availing himself of De Tonty's knowledge of the country, Iberville despatched a party under his lead to explore the river and its banks. They ascended to the Natchez country, 400 m. above the French fort, and here selected a site for a fort (which, however, was not erected until 16 years afterward), and called it Rosalie. A settlement was also made in 1703 on the Yazoo river, which was called St. Peter's. The colonies thus planted grew but slowly, and New Orleans, being founded soon after, drew off a large portion of the colonists from the interior, beside attracting the new emigrants; and unfortunately at a later period (1728) ill will grew up between the frontier settlers and the neighboring Indians. The consequence was a conspiracy of the savage tribes for the purpose of exterminating the whites, and in one day every vestige of civilization within the limits of the present state was swept away, and not fewer than 200 persons were killed, and twice that number of women, children, and negroes were made prisoners. The captives, however, were subsequently recovered and the Indians dispersed. A new and stronger fort was also erected at Natchez and supplied with heavy armament; and the French commander, following up his advantages, invaded the Natchez country and returned to New Orleans with 427 of the tribe, among whom were several chiefs, all of whom were soon after sent to St. Domingo and sold into slavery. The colony, though victorious, was much enfeebled by the war, and the destruction of the Indian trade, the main source of its prosperity. But one permanent benefit resulted from this, inasmuch as it induced the "Western Company," which had hitherto monopolized this profitable trade, to surrender its charter, and give to the king an opportunity of conferring on all his subjects equal privileges as to commerce within the

province. The population of the whole country (Louisiana) now exceeded 5,000 souls, of whom 2,000 were slaves, and settlement rapidly extended along the fertile banks of the Mississippi, Red, Arkansas, Washita, and other rivers; and at Natchez settlements had extended along St. Catharine's and Second creeks. Thus situated in 1788, the colony was ready for a new career of prosperity—free from commercial restrictions, with a well organized civil government, and religious instruction amply supplied by the vicar of New Orleans, which at this time belonged to the diocese of Quebec. But these gleams of prosperity were soon obscured by the "Chickasaw war." For a long time the Chickasaw tribe had been hostile to the French, and had incorporated into their nation the refugees of the Natchez when that tribe was broken up. They had completely destroyed the river trade, and kept the colony in constant alarm. Bienville at this conjuncture (1788) returned from France, bearing a commission from the king as governor and commandant-general of Louisiana. His name was once terrible to the savages, but by various combinations they had become strong, and the issue of the war which ensued was adverse to the whites; and at length, after about 10 years' administration of the province, Bienville was superseded by the marquis de Vaudreuil. For the next 10 years the settlements remained free from Indian hostilities, and increased in population and resources; but in 1752 the Chickasaws and Choctaws, encouraged by the English traders, again became hostile, and Vaudreuil determined to invade their country, but accomplished little. After the cession of the eastern part of Louisiana (including what is now Mississippi) to Great Britain in 1768, and until the war of the revolution, immigration into the territory proceeded rapidly. In 1798 the Mississippi territory was created by congress. Its boundaries were the Mississippi river on the W., the 81st parallel on the S., the Chattahoochee on the E., and a line drawn from the mouth of the Yazoo due E. on the N. The territory having been surrendered to the United States as part of Georgia, the consent of that state had been previously obtained to the establishment of a territorial government. This consent was followed several years afterward (1802) by the further cession by Georgia of all her lands S. of Tennessee, and these by an act of congress in 1804 were attached to the Mississippi territory, which thus comprised the whole of what are now the states of Alabama and Mississippi from the 81st to the 85th parallel. The territory below the 81st parallel, and between the Pearl and Perdido rivers, was added in 1811, having been wrested from Spain under the plea that it had originally formed a part of Louisiana. In March, 1817, Alabama was separated from Mississippi and organized under a territorial government of its own; and in December of the same year Mississippi was admitted into the Union as an independent state.

MISSISSIPPI. I. A. N. E. co. of Arkansas,

bordering on Missouri on the N., separated on the E. from Tennessee by the Mississippi river, bounded W. by the St. Francis river and Lake St. Francis, and intersected by Little river; area, 1,080 sq. m.; pop. in 1854, 2,266, of whom 541 were slaves. The surface is low and level, and in the drier portions very fertile; and there are a number of lakes, the largest of which is Big lake. In 1854, 192,200 bushels of Indian corn were produced, and in 1850, 201,250 bushels, beside 455 bales of cotton, and 21,273 lbs. of butter. Capital, Osceola. II. A. S. E. co. of Mo., bounded N., E., and S. by the Mississippi river, which separates it from Illinois and Kentucky, and drained by James and Cypress bayous; area, 380 sq. m.; pop. in 1854, 4,241, of whom 894 were slaves. The surface is level and the soil very fertile. In 1850 the productions were 854,700 bushels of corn, 3,777 of wheat, 4,985 of oats, and 1,050 lbs. of wool. There were 4 churches, and 190 scholars attending public schools. Capital, Charleston.

MISSISSIPPI RIVER (Indian, *Micchi Sepa*, spelled by some old writers, and interpreted by them the "Great River," and the "Great Father of Waters"), the principal river of North America, and in connection with its main branch, the Missouri, the longest river in the world. The smaller branch, which retains the name of the main lower current, was traced by Nicollet to a small rivulet in the extreme northern portion of the United States, in a region known as the Hauteurs de Terre, 1,600 feet above the level of tide, in lat. 47° 10' N. long. 94° 55' W. From this point the general course of the stream is southward; and as it flows on its long route to the gulf of Mexico into which it falls in lat. 29° N., it is continually receiving accessions to its current from rivers that flow on the one side from the western slopes of the Alleghanies, and on the other from the eastern slopes of the Rocky mountains. Its total length from its source to the gulf is computed by Nicollet at 2,946 m. But the main branch, the Missouri, the source of which is in the Rocky mountains in lat. 46° N., long. 118° 33' W., is itself 3,096 m. long to its junction with the Mississippi in lat. 38° 50' N., long. 90° 14' 45' W.; and the total length to the mouth of the river at the gulf of Mexico is 4,506 m. The area drained by the system of rivers, all of which unite in one main channel leading to the gulf, includes a large portion of the interior of North America, its limits E. and W. being the mountains respectively near the E. and W. side of the continent, and toward the N. the high lands in which rise the Red river of the North, the Assiniboine, and the Saskatchewan, tributaries of Hudson's bay and the Arctic ocean, and the waters which flow into the lakes of British America. Engelmann computes the areas of drainage of the principal branches as follows: of the Missouri, 814,000 sq. m.; Ohio, 202,400; the upper Mississippi, 184,500; the Arkansas, 176,700; Red river, 102,200; and the total area drained by the

Mississippi river above the mouth of the Red river to be 1,226,600 sq. m. The river and its numerous branches, reaching far back into the neighboring states and territories, present a network of navigable waters of vast extent, which, though their capacity of navigation is yet but partially developed, already far exceed in importance to man any other system of rivers upon the globe. The Mississippi is itself ascended by steamboats to the falls of St. Anthony, about 2,200 m.; and above these falls it is again navigable. From the head of the Ohio river at Pittsburg to the gulf of Mexico the distance is 2,418 m. Up the Missouri a steamboat passed in 1859 near to the Great falls at the E. foot of the Rocky mountains, a distance exceeding 3,950 m. from the gulf of Mexico. Arkansas and Red rivers are each navigable for more than 1,000 m.; and the Cumberland and Tennessee afford a water communication between the gulf and the extreme eastern portions of Kentucky and Tennessee. By the Illinois river steamboats penetrate far toward Lake Michigan; and it appears probable from the topography of this region that at some past period the waters of the great lakes flowed in this direction down the valley of the Mississippi. Toward the mouth of the river in Louisiana, the number of branches navigable to greater or less distances is estimated to exceed 1,500. In this state, below the mouth of Red river, the Mississippi is divided among numerous arms or passes, which leave the main channel, and pursue an independent course to the gulf. The highest of these is an important branch on the W. side of the river, called the Atchafalaya. Below its point of separation from the Mississippi the region of swampy lands, of bayous and creeks, is known as the delta. Above this the alluvial plain of the river extends to the Chains, 80 m. above the mouth of the Ohio, where precipitous rocky banks are first met with. These are the lower secondary limestone strata lying in nearly horizontal beds. The total length of the plain from the mouth of the Ohio to the gulf, is estimated at about 500 m. Its breadth at the upper extremity varies from 30 to 50 m.; at Memphis it is about 80 m., and at the mouth of White river 80 m. The extreme width of the delta is rated at 150 m., and its average width is probably 90 m. By the estimate of Mr. Forshey the total area of the alluvial plain is 31,200 sq. m., of which the delta is estimated to cover 14,000 m. According to Prof. Charles Ellet, jr., in his treatise entitled "Inundations of the Delta of the Mississippi" (Philadelphia, 1853), the northern extremity of the delta is elevated 275 feet above the surface of the sea, and is there and everywhere nearly level with low water in the Mississippi river. Its total descent, following the highest surface of the soil, is about 320 feet, or at the rate of 8 inches per mile. It is enclosed on the E. and W. by a line of bluffs of irregular height and extremely irregular direc-

tion, composed of strata of the eocene and later tertiary formations. Down this plain, which the river itself has raised up by the deposit of its sediments from the level of the sea, it flows in a serpentine course, frequently crowding on the hills to the left, and once passing to the opposite side, and washing the base of the western bluff at Helena. In its progress from the mouth of the Ohio to the gulf the actual length of the river is computed at 1,178 m., increasing the distance in a straight line by nearly 700 m., and by its flexures also reducing the rate of its descent to less than half the inclination of the plain down which it flows. When in the low water of the summer and winter the river is depressed, the fall at the head of the plain is about 40 feet, and near New Orleans 20 feet below the top of the banks. The current then flows sluggishly in a trough about 8,000 feet wide, 75 feet deep at the head, and 120 at the foot. The immense curves of the river in its course through the alluvial plain are remarkable features in its topography. They sweep around in half circles, and the river sometimes, after traversing 25 or 30 m., is brought within a mile or less of the place it had before passed. In heavy floods the waters occasionally burst through the tongue of land, and form what is called a "cut-off," which may become a new and permanent channel. The height of the banks and the great depth of the river bed check the frequent formation of these cut-offs, and attempts to produce them artificially have often failed, especially when the soil is a tough blue clay, which is not readily worn away by flowing water. This was the case at Bayou Sara, where in 1845 an excavation intended to turn the river was made, by which a circuit of 25 m. would have been reduced to a cut of one mile. The alluvial tract on each side of the river is for the most part a region of canebrakes, and forests of cypress growing in water. Lakes of semicircular form are scattered over its surface, which are deserted river bends. These are inhabited by alligators, wild fowl, and gar fish, which the steamboats have nearly driven away from the main river. In time of high water from floods, the river overflows its banks and makes its way into these lakes, slowly filling them up with the fine sediment that escapes the filtering action of the canebrakes, and is not deposited with the heavier sediments, which fall along the banks with the slackening of the currents. The low country around is then entirely submerged, and extensive seas spread out on either side, the river itself being marked by the clear broad band of water in the midst of the forests that appear above it. The great freshets usually occur in the spring from the melting of the snows about the sources of the river and its tributaries, and especially when this happens upon several of the great branches at such times that their swollen waters simultaneously enter the main river. These freshets are often attended with very seri-

ous consequences. Crevasses are formed in the banks and increase with the flow, which becomes so violent that flat boats are drawn into them and swept away with their crews into the intricacies of the swamps. At such times it is customary to send canoes to explore and rescue the boatmen who are in danger of being lost. Portions of the plain under cultivation are laid waste; and the planters often find it necessary to join their forces and raise levees along the banks for their protection. It is affirmed that the floods are becoming more frequent and disastrous, and this is ascribed to several causes, such as the diminished evaporation in the country above, as it becomes settled and its drainage improved; the extension of levees along the borders of the river and of its tributaries and outlets, which shut in the waters more and more, preventing their spreading over and losing themselves in the low lands; the cut-offs also cause a more rapid flow of the water, so that it is thrown with greater violence upon the districts below; and lastly, the progression of the delta into the gulf lessens the slope of the river near its mouth, and constantly retards the waters more and more to the damage of the regions above. The plans proposed to correct these evils depend upon state or national legislation for their efficient execution. They are: 1, the construction of higher, stronger, and better levees in lower Louisiana, the effect of which will be to secure the deepest and most capacious outlet; 2, the enlargement of the channel of the Atchafalaya, and making it an independent outlet for the waters of the Red river and the Washita; the enlargement of the Bayou Plaquemine will also afford some relief to the country below; 3, the prevention of additional cut-offs in the upper portions of the river and its branches; 4, the formation of an outlet of the greatest possible capacity from the Mississippi to the head of Lake Borgne, with the view of converting this ultimately into the main channel of the river; 5, it is recommended to form extensive reservoirs on the distant tributaries by placing dams across them, with apertures sufficient for their uniform discharge, so as to retain a portion of the water till the floods have subsided below; by this means the loss of the natural reservoirs destroyed by the levees would be in part compensated, the navigation of the tributaries be improved, and the violence of the floods below be proportionally abated.—The lower portion of the alluvial plain, called the delta, rises from a few inches to 10 feet only above the level of the sea, and is formed of sands and clays deposited in horizontal layers. In the steep banks of the Atchafalaya are noticed alternate beds of bluish clay, such as is brought down by the Mississippi, and of red ochreous earth, a deposit peculiar to the Red river, proving, as observed by Darby in his description of Louisiana, that at the period when these deposits were made the two rivers flowed alternately over this region. No distinction of this sort is

now observed in the sediments, as they are thoroughly mixed together below the junction of the two rivers before they are deposited. The delta protrudes far out into the gulf of Mexico beyond the general coast line, and is slowly but imperceptibly advancing into the gulf by the shoaling caused by the deposition of the sediment brought down the river. This is mostly dispersed by the waves and currents and carried far out into the gulf. For although the banks of the passes are sometimes observed to have advanced in the course of a few years sensibly into the gulf, these are but narrow strips of land, which may be swept away by the rush of the gulf waters driven up by storms; and the long coast of the delta at the same time has experienced no perceptible change. It is remarkable that, in this region of shifting sands and sediments, the old French maps of the early part of the last century should still very correctly represent many of the mud banks and channels or bayous around the Balize, which is the station of the pilot at the mouth of the river. Here only, for a distance of 100 m. from the gulf, is the river seriously obstructed by bars, which impede the passage of large vessels. Over these the depth of water is sometimes only 15 feet; but this is very changeable, as the channels are shifted by the floods in the river and the gulf storms. These bars are composed of blue clay mud through which vessels drawing 2 or 3 feet more water than the actual depth can be taken by steam tugs. Great efforts have been made to remove these obstructions by dredging; but the attempt is now given up as hopeless. It is found that in a single flood the channels may be quite filled up again. It has also been attempted to deepen the channel on the N.W. pass, which is the principal entrance of the river, by means of piles so driven as to confine the current within a limited width, and thus cause it to excavate its channel more deeply. This failed for the reason that the flow was directed more forcibly than before through other channels that remained open, and the effect was to deepen the pass known as À l'Ouvre, which for a time, afforded a better passage for vessels than the S.W. pass.—The sediment with which the lower Mississippi is charged is chiefly a fine clayey matter, so universally suspended in the water as to give it a thick muddy appearance. The upper Mississippi is a clear stream, but the Missouri pours into it a vast amount of whitish muddy matter, which renders the water so turbid, that at St. Louis one cannot see through a tumbler filled with it. This, however, does not prevent its being generally used for drinking, and for culinary purposes. Indeed, it is commonly preferred to any other water. The Ohio adds to it a current of reddish color; and the Arkansas and Red rivers pour in the red ochreous sediment already referred to; while the Mississippi itself excavates its alluvial plain and sweeps down, intermingled with the rest, vast quantities of vegetable matter

that falls in the banks of the river. The coarser pebbles and sands accumulate in the bends and eddies, forming bars, and the lighter materials are carried on to be deposited in the gulf of Mexico. Sir Charles Lyell, when he visited New Orleans in 1846, making use of the results of the observations of Dr. Riddell, Dr. Carpenter, and Mr. Forshey, attempted to estimate the annual discharge of sediment and of water, and the time that has probably been expended in the production of the delta. The mean annual amount of solid matter was found to be $\frac{1}{131}$ the weight of the water, or about $\frac{1}{338}$ the volume of the water. Adopting the average width, depth, and velocity, as given by these gentlemen, Lyell assumed 528 feet or $\frac{1}{8}$ of a mile as the probable thickness of the deposit of mud and sand in the delta; founding this conjecture on the depth of water in the gulf between the southern point of Florida and the Balize,* and partly on borings 600 feet deep, all in alluvial matter, in the delta near Lake Pontchartrain, N. of New Orleans. "The area of the delta being about 18,600 square statute miles, and the quantity of solid matter annually brought down by the river 8,702,758,400 cubic feet, it must have taken 67,000 years for the formation of the whole." In this estimate no allowance is made for the loss of fine sediment swept out into the gulf, nor does it include the deposits of the alluvial plain above the delta, which, allowing its depth to be 264 feet, and its area only equal that of the delta, would have required 88,500 years more for its accumulation. Mr. Forshey, in a publication made in 1850, presenting the results of observations extending through a period of 30 years, gives the average discharge of water for the year at Carrollton, 9 m. above New Orleans, as 447,199 cubic feet per second. By this estimate, Lyell observes, the number of years required to accomplish the result above alluded to would be reduced one eleventh. Mr. Forshey concluded that the cubic contents annually brought down equal 4,088,338,333 feet, enough to cover 12 miles square one foot deep. In 1851 and 1852, Mr. Forshey found the mean discharge continued through these years equal to 610,050 cubic feet per second; and the high water discharge equal to 1,059,925 cubic feet, the latter not including, of course, what escaped by the crevasse outlets below Red river. In the work of Prof. Ellet the total flow, including that of the Atchafalaya, in the flood of 1850, is referred to as 1,280,000 cubic feet per second. The discharge below New Orleans at the top of the flood of 1851 was 995,000 cubic feet per second, and at Memphis in 1850, 958,500 cubic feet. At the same time higher up the river the flow was much greater, being in June, 1851, one mile below the mouth of the Ohio, 1,228,-

000 feet, although the flood was 7 feet 10 inches below the high water of 1850; and in July, 1851, at Cape Girardeau, above the mouth of the Ohio, when the river was 4 feet below the high water of 1850, it was 1,025,000 cubic feet per second. This does not include the water which overflows the banks, and is lost in the swamps. The amount thus lost in the swamps of Missouri and northern Arkansas is estimated at 40 per cent. of the whole volume. The average flow of the river at Memphis, Tenn., was estimated in 1850 by R. A. Marr, U. S. N., to be 484,711 cubic feet per second—the amount in March varying per day from 46,138,127,380 cubic feet to 88,827,520,040, the river being 76 to 83 feet deep; and in October from 10,708,228,080 cubic feet to 16,892,279,100, the depth varying from 52.2 to 56 feet. According to this, the average flow is less than that given of the Ganges, which is 580,000 cubic feet per second.—The uniformity of width of the Mississippi river is very remarkable. At New Orleans it is somewhat less than half a mile wide, and from this it varies little for a distance of nearly 2,000 m., except that in the bends it swells out to 1½ or even 2 m. The junction of its principal branches produces no increase in the width, the maximum being attained before their entrance into the main river. Even when the Missouri, which is half a mile wide, joins its current to that of the Mississippi, the river below is of rather less width than that of either one above. The depth is very variable, sometimes reaching 188 feet, but the maximum is more commonly from 120 to 130 feet. The mean depth at high water mark is about the same at Carrollton and at Natchez, 300 m. further up. A section of the river at Carrollton, made at high water mark in 1849, comprises 168,226 square feet, and at Natchez 167,000 feet. The mean rate of descent for the first 100 m. above the mouth is 1.8 inches per mile; for the 2d 100 m., 2 inches; for the 3d, 2.8 inches; and for the 4th, 2.57 inches. The velocity of flow of the whole body of the river is variously estimated. Mr. Forshey makes the mean velocity at the surface, when the water is at a mean height, to exceed 2½ m. an hour. It varies at Carrollton from 1.45 m. per hour at low water, to 2.61 m. at high water. Prof. Ellet remarks that the mean velocity at the surface is 2 per cent. less than the velocity below the surface to near the bottom, the retardation at the top being caused by contact with the atmosphere.—The mouth of the river being some 1,400 m. nearer the equator than the source, and consequently about 2½ m. further from the centre of the earth, a curious question has been raised, which has excited some discussion: whether the river does not actually run from a lower to a higher level. The apparent paradox is explained by reference to the centrifugal motion of the earth, which causes the true horizontal level upon a large scale to be the earth's surface of equilibrium. It is the centrifugal motion of the earth that sus-

* The depth of 100 fathoms, given by Lyell, is probably far short of the actual average depth of the gulf. Within 10 m. of the mouth of the Mississippi it has been found to exceed 14,000 feet, and thence toward the Tortugas soundings have been made of 11,200 feet, or about 2½ m., without finding bottom.

tains the oceanic waters in the equatorial regions at greater distances from the centre than the level of the same waters in the temperate and polar latitudes; and if this motion were checked, the waters would then rush toward the poles, and the current of the Mississippi would be reversed.—The Mississippi, like the other great rivers of the West, is continually gathering into its current numbers of trees that fall into the stream, as the banks upon which they grew are undermined. Swept along by the great floods, they are frequently left in the main channels, their roots fixed to the bottom, and their tops, in part or entirely submerged, pointing down stream and swaying up and down from the motion of the current. In this condition they are known as snags and sawyers, and are greatly dreaded as presenting to boats ascending the river, especially at night, a most dangerous obstruction. To guard against their sinking the boats, these were formerly constructed with a water-tight compartment, called the snag chamber, in the bow, which, if pierced, might fill with water without endangering the boat. The navigation is now greatly improved by the continual care given to the removal of these obstructions; for which purpose, boats, called snag boats, provided with powerful machines for raising and drawing them away from the channels, are specially employed. The accumulations of the drift materials in the arms of the river have sometimes been so great as to completely bridge these over and extend for miles up the current. The obstruction is then known by the name of raft. From about the year 1778 such an accumulation had been gathering in the Atchafalaya, until in 1816 it had extended to full 10 m. in length, over 600 feet in width, and about 8 feet in depth. Though rising and falling with the water, it afforded a soil for the growth of bushes and of trees, some of which reached the height of 60 feet. In 1835 the state of Louisiana took measures to have it removed, and this was finally accomplished at a heavy cost in the course of 4 years. The Red river raft is still more famous for the large sums which have been appropriated by congress to effect its removal. The delta contains among its beds of clay and sand a vast number of ancient trunks of trees brought down and deposited by the river in distant periods of its history; and the soil also contains numerous trunks standing erect as if they had originally grown in these positions, and the surface had subsided with them to lower levels.—The first European explorer of the Mississippi valley was De Soto, who with his party reached the river in June, 1541, as is supposed not far below the site of Helena in Arkansas. (See De Soto.) In 1673 Marquette and Jolliet descended the river to within 8 days' journey of its mouth. La Salle, in 1682, descended the river to the gulf of Mexico, and took possession of the country in the name of the king of France. About the year 1699 Iberville built a fort upon the banks

of the river, and in 1703 the settlement of St. Peter's was made upon the Yazoo branch. New Orleans was laid out in 1718, and levees were immediately commenced, which were completed in front of the city 10 years afterward. At that time the levee system of lower Louisiana was fully established.

MISSOLONGHI, or MISSOLONGHI, a town of Greece, capital of the diocese of Ætolia, 24 m. W. from Lepanto, on the N. side of the gulf of Patras. It stands in a perfectly level plain 18 m. in length and 4 in breadth, watered by the Achelous and Evenus, and extending from the base of Mt. Aracynthus to the gulf. The walls are washed by the sea, but the water is so shallow that nothing larger than a small fishing boat can approach nearer than 4 or 5 miles. It is famous for the sieges it has sustained. In 1804 the town, which then contained 4,000 inhabitants, fell under the dominion of Ali Pasha. In 1821 it joined in the revolt of the Greeks against the Turks, and on Nov. 5 the Greek commander-in-chief, Prince Mavrocordato, and the famous partisan Marco Bozzaris, threw themselves with 400 men into the place, which was then almost deserted and scarcely defensible, the fortifications consisting only of a low and ruinous wall without bastions, and a small ditch in many places filled with rubbish. With no artillery but 14 old guns and scanty ammunition, Mavrocordato made a brilliant defence for more than two months against a Turkish army 14,000 strong, commanded by Omer Vrione, the most experienced of the Ottoman generals. On Nov. 28 the Greeks succeeded in throwing in reinforcements by sea, and the Turks were compelled to raise the siege, Jan. 6, 1822. The town was then fortified under the direction of English officers, at the expense of an Englishman named Murray, and was made one of the strongest places in Greece. In Sept., Oct., and Dec., 1823, Missolonghi was again besieged for 59 days by the Turks, and defended by Constantine Bozzaris, until it was relieved by Mavrocordato. Lord Byron came to Missolonghi in Jan. 1824, as a volunteer in the Greek cause, and died there, April 19. The last and greatest siege of Missolonghi, which occupied the attention of the civilized world for more than a year, began in April, 1825, when Reshid Pasha invested it with a large army, which was reinforced in July by the arrival of the capou pasha with a powerful fleet, and in Jan. 1826 by Ibrahim Pasha with an army of 20,000 Egyptians. The garrison of 5,000 Greeks, commanded by Noto Bozzaris, made a most valiant and desperate defence, repulsing repeated assaults, and, though suffering terribly from want of provisions, refusing to capitulate, notwithstanding repeated offers of the most favorable terms. At length, when continual bombardment had reduced the town to a heap of ruins and the last of their food had been consumed, at midnight of April 22, 1826, the garrison, placing the women in the centre, went forth in a body, and cutting their way through

the Turkish camp gained the shelter of the mountains, to the number of about 2,000. Those who were too feeble from hunger or from wounds to join in the sortie, assembled in a large mill which was used as a powder magazine, and when the Turks entered the town blew themselves up together with a large number of the enemy.

MISSOURI, one of the N. W. states of the American Union, and the 11th admitted under the federal constitution, situated between lat. 36° 30' and 40° 30' N., and long. 89° 2' and 95° 52' W.; length N. and S. 277 m.; average breadth about 244 m., varying from 200 m. in the N. to 312 m. in the S., and a narrow strip between the St. François and Mississippi rivers extending beyond the general body of the state $\frac{1}{2}$ ° southward into Arkansas; area, 67,-880 sq. m., or 43,123,200 acres, being 2.29 per cent. of the total territory of the United States. Missouri is bounded N. by Iowa; E. by Illinois, Kentucky, and Tennessee, from which the Mississippi river divides it; S. by Arkansas; and W. by the Indian, Kansas, and Nebraska territories, from which it is divided by a N. and S. line on the meridian of the mouth of Kansas river, and thence N. by the main channel of the Missouri river. The state is divided into 112 counties, viz.: Adair, Andrew, Atchison, Audrain, Barry, Barton, Bates, Benton, Bollinger, Boone, Buchanan, Butler, Caldwell, Callaway, Camden, Cape Girardeau, Carroll, Cass, Cedar, Chariton, Clark, Clay, Clinton, Cole, Cooper, Crawford, Dade, Dallas, Daviess, De Kalb, Dent, Dodge, Douglas, Dunklin, Franklin, Gasconade, Gentry, Greene, Grundy, Harrison, Henry, Hickory, Holt, Howard, Howell, Iron, Jackson, Jasper, Jefferson, Johnson, Knox, La Clede, Lafayette, Lawrence, Lewis, Lincoln, Linn, Livingston, McDonald, Macon, Madison, Maries, Marion, Mercer, Miller, Mississippi, Moniteau, Monroe, Montgomery, Morgan, New Madrid, Newton, Nodaway, Oregon, Osage, Ozark, Pemiscot, Perry, Pettis, Phelps, Pike, Platte, Polk, Pulaski, Putnam, Ralls, Randolph, Ray, Reynolds, Ripley, St. Charles, St. Clair, St. François, Ste. Genevieve, St. Louis, Saline, Schuyler, Scotland, Scott, Shannon, Shelby, Stoddard, Stone, Sullivan, Taney, Texas, Vernon, Warren, Washington, Wayne, Webster, Wright. The principal towns and cities are Jefferson City, the capital, St. Louis, Booneville, Cape Girardeau, Hannibal, Independence, Lexington, St. Joseph, and Kansas City.—The population of Missouri, according to the federal enumerations taken decennially, has been as follows:

Year.	White.	Free colored.	Slaves.	Total population.	Increase per cent.
1810.....	17,227	607	2,011	20,845
1820.....	55,988	376	10,229	66,586	219.43
1830.....	114,795	569	25,091	140,455	110.94
1840.....	223,888	1,574	53,240	283,702	173.18
1850.....	592,004	2,618	87,423	682,044	77.75

The following censuses have been taken quadrennially under state authority:

Years.	White.	Free colored.	Slaves.	Total.
1848.....	510,435	1,779	76,757	588,971
1852.....	684,984	2,526	87,207	794,687
1856.....	806,744	2,652	101,605	911,001

Density of population in 1850, 10.12 to the square mile; ratio to the total population of the Union, 2.94 per cent. The density in 1856 was 13.52 to the square mile. Of the white population in 1850 (86.80 per cent.), 312,987 were males and 279,017 females; of the free colored (0.88 per cent.), 1,361 males and 1,257 females; and of the slaves (12.82 per cent.), 43,484 males and 43,938 females. Of the free colored, 687 were blacks and 931 mulattoes; of the slaves, 74,187 blacks and 13,235 mulattoes. The white and free colored inhabited 96,849 dwellings, and constituted 100,890 families. Births (white and free colored) in 1849-'50, 19,632 (3.30 per cent.); marriages, 6,989 (1.17 per cent.); deaths, 10,937 (1.60 per cent.), and including slaves, 12,292 (1.80 per cent). Deaf and dumb, 282; blind, 232; insane, 262; idiotic, 357. Of the white and free colored population (594,622) there were born in the United States 520,826 (87.59 per cent.); in foreign countries, 72,474 (12.19 per cent.); and in unknown parts, 1,322 (0.22 per cent.). Of the native-born, Missouri supplied 277,604, Kentucky 69,694, Tennessee 44,970, Virginia 40,777, North Carolina 17,009, Indiana 12,752, Ohio 12,737, Illinois 10,917, Pennsylvania 8,291, New York 5,040, Maryland 4,253, South Carolina 2,919, Arkansas 2,120, Alabama 2,067, Iowa 1,366, Georgia 1,254, and Massachusetts 1,103. Of the foreign-born, there were from the United Kingdom 21,338 (Ireland 14,734), British America 1,053, France 2,138, and Germany 45,120. Ages of the total population: under 1 year, 22,331; 1 and under 5 years, 93,947; 5 and under 10, 105,176; 10 and under 15, 92,344; 15 and under 20, 75,537; 20 and under 30, 125,334; 30 and under 40, 80,372; 40 and under 50, 47,054; 50 and under 60, 24,702; 60 and under 70, 10,705; 70 and under 80, 3,369; 80 and under 90, 831; 90 and under 100, 142; 100 and upward, 45; unknown, 155. The occupations of 128,175 free male persons over 15 years of age in 1850 were as follows: commerce, trade, manufactures, mechanic arts, and mining, 30,098; agriculture, 65,561; labor not agricultural, 20,326; army, 305; sea and river navigation, 2,471; law, medicine, and divinity, 2,898; other pursuits requiring education, 3,147; government civil service, 767; domestic service, 1,458; other pursuits, 1,149. The number employed in manufacturing establishments in 1820 was 1,952; in 1840, 11,100; and in 1850, 16,850. The number of slaveholders in 1850 was 19,185, viz.: holders of 1 slave, 5,762; of 1 and under 5, 6,878; of 5 and under 10, 4,370; of 10 and under 20, 1,810; of 20 and under 50, 545; of 50 and under 100, 19; and between 200 and 300, 1. The federal representative population of Missouri in 1850 was 647,075, and entitled the state to 7 members of congress.—The Mis-

Missouri river divides this state into two distinct parts, each marked by a different configuration. The S. part consists of an undulating country, rising into mountains as it approaches the Ozark range. That portion N. of the river is more level, but sufficiently diversified to permit of drainage. Looking at these districts more in detail, and beginning with the extreme S. E., we find an extensive bottom land along the Mississippi, commencing on the N. at Cape Girardeau and extending S. to the Arkansas river. It includes many swamps which are rendered almost impenetrable by a dense growth of trees, mostly cypress. The most extensive of these, called the Great swamp, commences a few miles S. of Cape Girardeau and passes S. to the mouth of the St. François, penetrating far into the state of Arkansas. More than 100 m. of this swamp are in Missouri. Within the bottom are also many lakes and lagoons; but it likewise contains many islands elevated above the reach of the highest floods. Since the earthquakes of 1811-'12 much of this tract has been inundated and uncultivated; but it is capable of being reclaimed, and has a very fertile soil. The highlands along the Mississippi begin a little below Cape Girardeau, and extend up to the mouth of the Missouri river. The highest part is that between Ste. Genevieve and the Maramec river, where the banks of the river, composed of solid masses of limestone, rise occasionally 360 feet above the water. This highland and undulating country extends westwardly across the entire breadth of the state, its rugged character however disappearing as the Osage river is approached. This is one of the least populous sections of the state, but it is one of the most picturesque and interesting in the world. It has a mild, dry, and genial climate. Between the Gasconade and Osage, both of which are affluents of the Missouri, a range of low hills approaches that river, rising from 150 to 200 feet above its mean level. They are thinly wooded, and constitute the northernmost offset of the Ozark mountains, a region of which the undulating country on the E. may be considered as the lowest portion. This elevated tract covers more than half of that portion of the state S. of the Missouri. The surface is extremely broken and hilly; the hills, which rise from 500 to more than 1,000 feet above their bases, are exceedingly numerous, but do not form continuous ranges, being divided into knobs and peaks with rounded summits, and presenting perpendicular cliffs and abrupt precipices of sandstone. The soil covering them is generally shallow, and overgrown almost exclusively with pitch pine, cedar, and bramble. Along the numerous rivers which originate in this tract are bottoms of moderate extent and tolerable fertility, but they are subject to heavy floods. To the W. of this region, the country, especially the basin of the Osage, is chiefly a rolling prairie, diversified with forests of stunted timber; and to the N., along both sides of the Missouri, extends a rich alluvial bottom

which is probably more fertile and better settled than any other district, with the exception of the country about the confluence of the river with the Mississippi. A large part of this prolific region is still, however, in a state of nature, and covered with a deep and heavy growth of timber. In the country N. of the Missouri, which comprehends about one third of the state, the surface is generally rolling or level. The bottoms along the Missouri and Mississippi are remarkably fertile. Between these two large rivers the country is much diversified by the broad valleys of their subsidiary streams, and intervening tracts of undulating upland which are united with the valleys by gentle slopes. The woodlands occur only on the margins of the water courses, and the uplands are extensive prairies completely destitute of a timber growth. These prairies occupy at least nine tenths of the whole region, and comprehend some of the best lands of the state.—The great rivers of Missouri are the Mississippi, which washes the E. boundary for 470 m., and the Missouri, which, after forming a large part of the W. boundary, crosses the state in a direction E. by S. to its junction with the Mississippi. Among their affluents are the White and St. François rivers, which drain large sections in the S. part of this state, but are properly rivers of Arkansas. The Maramec, which enters the Mississippi 20 m. below St. Louis, has a course not exceeding 180 m. Salt river, which joins the Mississippi 65 m. above the confluence of the Missouri, runs for more than 200 m. with a gentle course through a tolerably fertile bottom land. There are other considerable streams flowing into the Mississippi both above and below the Salt, which afford extensive mill power. Of the affluents of the Missouri from this state the most considerable are the Osage and Gasconade. The Gasconade is important chiefly for the supplies of timber which it furnishes, and also for its vast water power for manufacturing purposes; its length is about 120 m. The Osage rises in the plains between the Arkansas and Kansas rivers, and flows in a general E. N. E. direction about 400 m., joining the Missouri near the centre of the state; it is 875 yards wide at its mouth, and is navigable for light draught steamboats through half its course. The Chariton, Grand, Platte, and Nodaway rivers are affluents from the N., and each is navigable for some distance. The Grand spreads out into numerous branches, and drains a large section of the middle prairie.—The range of the geological formations of Missouri is almost limited to those groups which are comprised between the lower silurian rocks and the upper coal measures. The drift formation is spread over the northern portion of the state, the river bottoms are formed of alluvium, and beds of clay and marl, called the bluff loess, of an age intermediate between the drift and alluvium, cap the river hills. In the southern and central portion of the state ridges of porphyritic rocks are traced in an E. and W. direction, and among these and at their contact with the silu-

rian limestones occur important deposits of iron ores and other metallic productions. The upper and middle portions of the coal measures attain together a thickness of 500 feet, and are spread over the N. W. part of the state, being a continuation of the coal formation of Iowa. The coal beds are few and small, and the coal is of highly bituminous character. The lower portion of the coal formation, measuring about 140 feet in thickness, is more productive in coal, and is worked in St. Louis co. It is thence traced westward across the state in most of the counties lying near the Missouri river on the S. side. Below the coal measures the formations are mostly of calcareous character, some of which are identified with those of the eastern states. They are named as follows by Prof. G. C. Swallow, the state geologist. The carboniferous limestone is subdivided into 4 members, viz., ferruginous sandstone, 195 feet thick; St. Louis limestone, 250 feet; Archimedes limestone, 200 feet; and the lowest, encrinital limestone, 500 feet. The devonian series is represented by the Chouteau limestone, vermicular sandstone and shales, lithographic limestone, Hamilton group, and Onondaga limestone, the total thickness amounting to about 880 feet; the upper silurian by the delthyris shaly limestone, 175 feet, and the Cape Girardeau limestone, 45 feet thick; the lower silurian by the Hudson river group, 120 feet, Trenton limestone, 360 feet, and alternating formations, 4 of magnesian limestone, and 3 of sandstone, the aggregate thickness of which is over 1,100 feet, the 3 sandstone formations making of this only about 250 feet. These groups are above the Potsdam sandstone, the occurrence of which has not been observed in the state. The 3d magnesian limestone is eminently the lead-bearing rock, but many mines are also worked in the 2d or next upper limestone. Hematite iron ores abound in these calcareous formations. The sandstones afford excellent sand for the manufacture of glass. The stratified rocks throughout the state lie in a nearly horizontal position, and their undulations are everywhere gentle. Even where they meet the azoic formations, as the porphyries of the Iron mountain and Pilot Knob range, they are not disturbed in their position. For further notice of the mineral productions of Missouri, reference may be made to the articles COAL, COBALT, COPPER, IRON, IRON MOUNTAIN, and LEAD.—The climate of Missouri is in some respects extreme. The winters are sometimes long and severe, the summers often hot; but sudden and frequent changes of temperature occur. The mean annual temperature at Jefferson Barracks (lat. 38° 28', elevation 472 feet) for 26 years was 55.46°, distributed to the seasons thus: spring, 56.15°; summer, 76.19°; autumn, 55.68°; winter, 33.85°. The lowest monthly mean in this period was 18.54°, and the highest 85.90°. The annual rain fall is 37.88 inches, distributed as follows: spring, 10.56 inches; summer, 12.88; autumn, 8.02; winter, 6.37.—

The soils in most of the uplands are formed by the disintegration of sandstones and limestones. The arenaceous soils of the rolling prairies of the north are often very fertile; and so also are the soils formed from the decomposition of the carboniferous limestones, especially in the vicinity of the streams. In the S. districts along the river bottoms, where clay abounds, an excellent soil is found. Maize, wheat, oats, and tobacco appear at the present time to form the staple productions of the state. Cotton was formerly grown in the southern counties, but its culture is now abandoned, and hemp and flax have taken its place. The peach, nectarine, apple, and pear are cultivated, and the wild grape abounds. The Catawba and other improved varieties of grape are extensively cultivated in several counties, and large quantities of wine are annually produced. The prairies form excellent pasture lands, and the bottoms furnish canes and rushes for winter fodder. Sheep farming is also successfully and extensively pursued, and swine are very numerous, being readily raised in the forests. Elk and deer are still met with in herds on the prairies W. of the Ozark mountains, and many fur-bearing animals in the unsettled parts, but in too small numbers to be profitable to the hunter.—The number of farms and plantations in Missouri in 1850 was 54,458, occupying 9,782,670 acres of land, 2,988,425 acres of which were improved; and the whole was valued at \$63,225,543. The value of implements and machinery was \$3,981,525. The live stock in the same year consisted of 225,319 horses, 41,667 asses and mules, 280,169 milch cows, 112,168 working oxen, 449,178 other cattle, 762,511 sheep, and 1,702,625 swine; value of live stock, \$19,887,580; value of animals slaughtered in 1849-'50, \$3,867,106. Products of animals: butter, 7,834,359 lbs.; cheese, 203,572; wool, 1,627,164. The crops of 1849 were as follows: wheat, 2,981,652 bushels; rye, 44,268; oats, 5,278,079; Indian corn, 36,214,587; barley, 9,631; buckwheat, 23,641; Irish potatoes, 989,006; sweet potatoes, 335,505; hay, 116,925 tons; hops, 4,180 lbs.; clover seed, 619, and other grass seed, 4,846 bushels; peas and beans, 46,017 bushels; beeswax and honey, 1,328,972 lbs.; flax seed, 13,696 bushels; flax, 627,160 lbs.; hemp, dew-rotted, 15,968, and water-rotted, 60 tons (45.96 per cent. of the whole product of the Union); maple sugar, 178,910 lbs.; molasses, 5,636 galls.; rough rice, 700 lbs.; tobacco, 17,118,784 lbs.; silk cocoons, 186 lbs.; wine, 10,563 galls. The value of the produce of market gardens was \$99,454, and of orchards \$514,711. Value of home manufactures, \$1,674,705. The total value of the agricultural products of the state in 1840 was \$9,755,615, and in 1850 \$34,619,640. The average production to the acre in Missouri is: wheat, 11 bushels; Indian corn, 34; oats, 26; Irish potatoes, 110; tobacco, 775 lbs.; hay, 1½ tons; dew-rotted hemp, 775 lbs.—The statistics of the manufactures, &c., of the state in 1850 were as follows: establishments, 3,029;

capital, \$9,079,695; raw material used, \$12,-446,788; hands, 15,977 males and 873 females; annual wages, \$8,184,764; product of the year, \$28,749,265. Among the manufactories are noted 2 cotton mills, capital \$102,000; 1 woollen mill, \$20,000; 5 pig iron works, \$619,000; 6 cast iron works, \$187,000; 2 wrought iron works, \$42,100; 22 distilleries and breweries, \$298,900. The total value of manufactures produced in the state in 1840 was only \$5,946,759, showing an increase in 10 years of \$17,802,506, or about 300 per cent.—Missouri had in 1854 about 400 direct importers of foreign goods. Its domestic trade is immense; centring at St. Louis, the commercial depot of the upper section of the great valley, it extends in every direction. Its steamboats are found at New Orleans and St. Paul; at Pittsburg, Cincinnati, and Louisville on the Ohio river; at Fort Union at the mouth of the Yellowstone; and at Kansas City on the Missouri. Between 3,000 and 4,000 steamers arrive and depart annually. The interior is reached by river, railroad, and turnpike, but is not everywhere well accommodated with means of intercommunication. In 1850 the shipping owned in the state amounted to 28,907 (steam 24,955) tons, and in 1859 to 60,760 (steam 54,516) tons, of which a large portion was built within the state.—The railroads of Missouri, with two exceptions, have their initial point at St. Louis; these are the Pacific, with a direct westerly course to the Kansas line of 280 m., and its S. W. branch, which takes the course indicated by its name, leaving the main line at Franklin, and terminating in the S. W. corner of the state, with a length of 282 m.; the North Missouri, which passes N. W. to the southern line of Iowa, with a length of 286 m.; and the St. Louis and Iron mountain, which has its S. terminus at Pilot Knob, 86½ m. distant from St. Louis. The Hannibal and St. Joseph railroad extends across the state 206 m. Other railroads in progress or projected are: the Cairo and Fulton, the length of which in this state is 77 m.; the Keokuk and Kansas, the Canton and Bloomfield, the Lexington and St. Louis, the Cape Girardeau and Pilot Knob, the Randolph and Chariton, and the Platte country railroads. The completed portion of these railroads and their cost to the end of 1859 were as follows:

Railroads.	Miles.	Cost.
Cairo and Fulton.....	21	\$420,866
Hannibal and St. Joseph.....	206	7,659,705
Quincy and Palmyra.....	12	900,000
North Missouri.....	188	5,632,531
Pacific.....	168	10,033,823
S. W. Branch.....	48	1,442,710
St. Louis and Iron Mountain.....	84½	5,900,744
Total.....	719½	\$30,589,869

In the cost is probably included that of other portions of the several roads in progress. The building of these roads has been aided by grants of land by congress and by bonds guaranteed by the state. The length of post routes at the end of June, 1858, was 14,685 m., of which 205 m. were by railroad, 614 m. steam naviga-

tion, 8,156 m. coach road, and 10,710 m. not specified. The telegraph connects all the river towns with St. Louis, and the most important towns are connected with the lines extending to the Atlantic seaboard. On Jan. 1, 1860, Missouri had 9 banks, the condition of which was as follows: Liabilities: capital, \$5,796,-781; circulation, \$4,157,886; deposits, \$3,-894,623; profits on hand, \$805,001. Resources: notes, bills of exchange, &c., \$10,814,877; specie, \$4,169,905; real estate, \$169,459; total, \$14,654,241.—The constitution of Missouri grants the elective franchise to every free white male citizen of the United States, 21 years of age, who has resided in the state 1 year and in the place of voting 3 months. General elections are held on the 1st Monday in August. The general assembly is composed of a senate of 18 members, elected in districts for 4 years, one half biennially, and a house of representatives of 49 members, elected for 2 years. Senators must be 30 years of age, and have resided in the state 5 years; and representatives must have resided in the district from which chosen 2 years. Both must be citizens of the United States. The legislature meets at Jefferson City biennially (even years), on the last Monday of December. The governor (salary \$8,000 and furnished house) and the lieutenant-governor (paid as president of the senate \$7 per day while sitting) are elected by the people at large for 4 years, and cannot serve 2 terms successively; they must be native-born citizens, or have been citizens of the United States in 1820, or inhabitants at the period of the cession by France in 1803. The principal administrative officers are the secretary of state (salary \$1,800 and fees), superintendent of public schools (\$1,500), auditor (\$1,850 and fees), treasurer (\$1,850 and fees), attorney-general (\$1,600 and fees), &c. Most of the above officers are required to reside at the capital during their terms of office. The judiciary consists of a supreme court, 16 circuit courts, county courts, &c. The supreme court has 8 justices (salary \$3,000) elected for 6 years, and holds two sessions annually, one at Jefferson City and one at St. Louis. A circuit court is held twice a year in each county. Its jurisdiction extends to all matters of tort and contract over \$90 where the demand is liquidated, and over \$50 where the agreement is parole. It has exclusive commercial jurisdiction, and a supervision over the county courts and justices of the peace, subject however to the correction of the supreme court. The judges of the circuit courts (salary \$1,500) are elected in their respective districts for 6 years. The jurisdiction of the county courts is limited to matters of probate and local affairs; the county court is composed of 3 justices elected for 4 years. In addition to the circuit and county courts, St. Louis has a court of common pleas (with jurisdiction similar to the circuit court), a criminal court, a district court of probate, a recorder's court, and a land court, having sole jurisdiction in St. Louis county in

suits respecting lands, actions of ejectment, dower, partition, &c. Judges of the common pleas and criminal courts are elected for the same term as the circuit judges. Hannibal, St. Joseph, Cape Girardeau, Independence, and Weston have also separate courts of common pleas.—The revenue of the state is derived principally from taxation, poll tax, licenses, bank stock dividends, &c. The resources of the treasury for the two years ending Sept. 30, 1850, amounted to \$1,192,498, and for the two years ending Sept. 30, 1858, to \$1,861,368. The expenditures for the same periods were \$871,818 and \$1,182,175. The state debt proper amounts to \$602,000, on which the annual interest is \$35,805. The state has also lent its credit to railroad companies to the large amount of \$20,101,000, and will increase this to \$24,950,000. The following was the condition of the railroad loans, July 18, 1859:

Name of company.	Amount authorized.	Amount issued.	Amount to be issued.
Hannibal and St. Joseph.	\$3,000,000	\$3,000,000
Pacific, main line	7,000,000	7,000,000
" S. W. branch	4,500,000	1,900,000	\$2,600,000
North Missouri	5,500,000	4,850,000	1,150,000
St. Louis and Iron Mt'n..	3,600,000	3,501,000	99,000
Cairo and Fulton	650,000	350,000	300,000
Platte Country	700,000	700,000
Total	\$24,950,000	\$20,101,000	\$4,849,000

As security for these bonds the state holds mortgages on the roads and their properties, also on the lands granted by congress in aid of their construction. The assessed valuation of taxable property in the state in 1850 was \$98,595,463, and in 1857 \$268,789,241. The principal institutions supported wholly or in part by the state are the state lunatic asylum and the deaf and dumb asylum, both at Fulton, the asylum for the blind at St. Louis, and the state prison at Jefferson City. Whole number of paupers supported in whole or part within the year ending June 1, 1850, 2,977; number at that date, 505; annual cost of support, \$58,243. Whole number of criminals convicted within the same year, 908; number in prison at that date, 180.—In 1850 the number of children returned as having attended school any part of the year was 95,285, or one in every 6.23 of the free population. The school statistics as reported on June 1 of the same year were as follows: 1,570 primary and public schools, with 1,620 teachers, 51,754 scholars, and an annual income of \$160,770; 204 academies and private schools, with 868 teachers, 8,829 scholars, and an income of \$143,171; 9 universities and colleges, with 65 teachers, 1,009 students, and an income of \$79,528; total, 1,783 institutions, with 2,053 teachers, 61,592 scholars, and an income of \$383,469. In 1858 there were in operation 3,882 common schools, with 4,397 teachers. The school fund held by the state amounts to \$575,668, the interest from which is distributed semi-annually to the counties *pro rata*; and one fourth part of the whole revenue of the state is appropriated for the support of common schools. The number of free persons

over 20 years of age in 1850 unable to read and write was 86,778, of whom 86,281 were whites and 497 free colored persons. The principal collegiate and professional schools within the state are: the university of St. Louis at St. Louis, founded in 1832, and its medical department, 1836; St. Charles college at St. Charles, 1837; Missouri university at Columbia, 1842, and its medical department at St. Louis, &c., 1846; St. Vincent's college at Cape Girardeau, 1843; Masonic college at Lexington, 1844; Fayette college at Fayette, 1848; Westminster college at Fulton, 1851; Chapel Hill college at Chapel Hill, 1852; William Jewett college at Webster, 1852; Grand River college at Trenton, 1855; theological seminary (R. O.) at St. Louis; St. Mary's ecclesiastical (R. O.) seminary at Barrens, Perry co., and a number of other theological schools, &c.—The whole number of churches in the state in 1850 was 880, with accommodation for 251,068 persons, and valued as property at \$1,561,610. Of these, 304 were Baptist churches, 57 Christian, 11 Episcopal, 18 free, 2 Jewish, 24 Lutheran, 1 Mennonite, 268 Methodist, 3 Moravian, 128 Presbyterian, 68 Roman Catholic, 11 union, 2 Unitarian, 1 Universalist, and 21 others. The number of newspapers and periodicals in 1850 was 61, which circulated annually 6,195,560 copies; of these, 5 (3,380,400 copies) were published daily, 4 (278,000 copies) tri-weekly, 45 (2,406,560 copies) weekly, and 7 (185,600 copies) monthly; and 17 (608,800 copies) were literary and miscellaneous, 42 (5,496,280) political, and 2 (90,480) religious. The number of libraries in the state, other than private, was 97, containing 75,056 volumes, viz.: 18 (23,106 vols.) public, 18 (17,150 vols.) school, 66 (14,500 vols.) Sunday school, 4 (19,700 vols.) college, and 1 (600) church.—In legal proceedings the region now known as Missouri was included by the French and Spanish in the Illinois country, but popularly and historically it was denominated Upper Louisiana. The states of Arkansas and Iowa and the great territories of Kansas and Nebraska were parts of the same grand division. Situated in the central part of the valley, the settlement and progress of Missouri were later and less rapid than those of the lower districts; but as early as 1720 its lead mines had already attracted attention. In 1755 Ste. Genevieve, its oldest town, was founded. In 1763 the jurisdiction of the country passed from France to Spain and England, the Mississippi being the dividing line between their respective apportionments. France had been despoiled of all her North American possessions. During the contest numbers of Canadian French emigrated by way of the lakes, and going south settled in both Upper and Lower Louisiana, giving the first impulse to the permanent settlement of Missouri; and a flourishing river trade sprang up between the two sections. The character of the new government (Spanish) was conciliatory; lands were granted liberally to the colonists, and numerous emigrants from Spain flocked into the country. In 1775 St. Louis,

originally a depot for the fur trade, contained 800 inhabitants, and Ste. Genevieve about 460. At this time the American revolution was commencing, and Spain, siding with the colonists, entered into hostilities against England. In Lower Louisiana and Florida the arms of Spain were successful; but in 1780 St. Louis was attacked by a body of English and Indians from Michilimackinac, and was only relieved by the timely arrival of Gen. Clark from Kaskaskia. The general peace of 1783 put an end to hostilities; Spain retained her previous possessions, and received in addition the whole of Florida, of which she had been deprived 20 years before; and the eastern bank of the Mississippi, including all the Illinois country, was ceded to the United States. Emigration into Spanish Louisiana began once more on the restoration of peace, and many persons from the western part of the United States moved into Missouri. Disputes soon arose between Spain and the United States. A disagreement relative to the navigation of the great river was settled by treaty in 1795, by which Spain granted to the United States free navigation; but the stipulations on the part of Spain were not faithfully carried out, and it is probable that war would have broken out had not the country been ceded back in 1800 to France, by which it was sold to the United States in 1803. The country purchased was immediately divided into the "territory of Orleans" and the "district of Louisiana." The latter was erected in 1805 into the territory of Louisiana, and St. Louis became the seat of its government. In 1812, on the admission of the present state of Louisiana into the Union, the name of the territory was changed to Missouri, and its government made representative. The limits on the west were gradually extended by treaties with the Indians. In 1810 the population numbered 20,845, of whom all but about 1,500 belonging to Arkansas were settled within the present limits of Missouri. Immigration now came in rapidly from the East. In 1817 the total population had increased to 60,000, and St. Louis counted at this time 5,000 inhabitants. It had already become the emporium of the upper Mississippi. In this year the assembly applied to congress for permission to frame a state constitution preliminary to admission into the Union. Now commenced that great struggle to prevent the extension of slavery into the new states, which was settled by the celebrated compromise of 1820, whereby it was determined that Missouri should come into the Union as a slaveholding state, but that slavery should never be established in any states formed in the future from the lands lying to the N. of lat. $36^{\circ} 30'$. The state constitution was framed by a convention of 40 delegates convened at St. Louis, July 19, 1820; and the state was admitted by proclamation of the president, Aug. 10, 1821, on the compliance of the legislature of Missouri with the requirements of the act of congress passed Feb. 27 of that year. From this time until the

present the progress of the state in material prosperity has been rapid; immigration has constantly been augmenting its population, which by the U. S. census of 1860 probably amounts to about 1,200,000; and agriculture, mining, commerce, and manufactures have been expanded into vast interests, whose products are rapidly increasing in value and importance.

MISSOURI (*i. e.*, Mud river), a large river of the United States, and the principal tributary of the Mississippi. It properly forms one stream with the Mississippi, being much greater in length and volume than the other branch which bears that name above the mouth of the Missouri. It rises near the boundary between Oregon and Nebraska, but within the latter territory, among the Rocky mountains, in several small streams, the principal of which are Jefferson and Wisdom rivers (the latter rising within a mile of the head springs of Clark's fork of the Columbia), whose sources lie between lat. $44^{\circ} 20'$ and $45^{\circ} 35'$ N. and long. 112° and 114° W., and which unite about lat. $45^{\circ} 15'$, long. 112° . According to some geographers, however, the Missouri properly begins about 80 m. further E., where the stream formed by the Jefferson and Wisdom, which on this hypothesis retains thus far the former name, is joined by the Madison and Gallatin. After a direct course N. from the latter point to about lat. 44° , the Missouri runs E. to the frontier of Dacotah, where it is joined by (lesser) White Earth river. Its general direction is S. E. thence to the Mississippi, which it joins in lat. $38^{\circ} 50' 50''$ N., long. $90^{\circ} 14' 45''$ W., after separating Nebraska on the W. from Dacotah and Iowa on the E. forming a small part of the dividing line between Missouri and Kansas and Nebraska, and also flowing across the whole state of Missouri. Its length is 3,096 m., which, added to 1,410 m., the length of the lower Mississippi, makes its whole course, from its source to the gulf, 4,506 m. It has commonly been navigated as far as the mouth of the Yellowstone, in the N. E. part of Nebraska, but it may be ascended by steamboats much further than this, to the Great falls almost at the very base of the mountains, and about 2,540 m. from the Mississippi. There is no serious obstruction to navigation below this point, though at certain seasons of the year the water is shallow, owing to its passing through a dry and open country in its upper course, and being subject to extensive evaporation. It is generally turbid and rapid. In its lower course it is bordered by a narrow alluvial valley of great fertility, back of which lie generally extensive prairies. At its mouth it is over half a mile wide, and in many places it is much wider. Its principal tributaries are the Yellowstone, Little Missouri, Big Cheyenne, (greater) White Earth, Niobrara, Platte or Nebraska, Kansas, and Osage on the right, and the Milk, Dacotah, Big Sioux, Little Sioux, and Grand on the left. The Yellowstone drains the whole of central and a large part of western Nebraska, collecting the waters of a great number of smaller streams

which flow between the Black hills and the Rocky mountains. It is 800 yards wide at its mouth, or about equal in size to the Missouri at the point of junction. The Little Missouri comes from the valley between the Black and Turtle hills, running almost parallel with the Yellowstone, and is about 800 m. long. The Cheyenne or Washteg and greater White Earth or Mankizitah rise near the S. base of the Black hills, in the central part of Nebraska, and flow E.; the former is 400 yards wide at its mouth, and the latter 300. The Ni-obrarah, or Eau qui Court, is formed by two considerable streams, one of which rises near the source of the White Earth and the other further to the S.; its length from its remotest source is not much under 500 m. The North fork of the Nebraska or Platte river rises near the N. W. corner of Kansas, and makes a long detour to the N. W., almost interlocking with the head streams of the Yellowstone. It then flows S. E., and in lat. 41° , long. $100^{\circ} 30'$, is joined by the South fork, which has its sources about Pike's peak. The united stream thus drains the whole of southern Nebraska, and falls into the Missouri 600 m. from its mouth, being 600 yards wide at the point of confluence. The constituents of the Kansas river are the Republican and Smoky Hill forks, which water the N. and central parts of the territory, and the Kansas also receives numerous smaller tributaries; its width at its mouth is 233 yards. The Osage, about 400 yards wide at the point of junction, is the principal stream of southern Missouri. The Milk river, on the left bank, draws its waters partly from British America. The Dacotah, Tchansansan, or Rivière à Jacques, is the principal water course of Dacotah, and is 450 or 500 m. long. The Big Sioux runs nearly parallel with it at a distance of about 50 m., and its length may be estimated at 300 m.; its embouchure is 110 yards wide. The Little Sioux, or Inyan Yankey, belongs to the western part of Iowa. Grand river rises in southern Iowa, and drains the N. W. part of Missouri; its width at its mouth is 190 yards. It will thus be seen that the Missouri receives all the great rivers which rise on the eastern declivity of the Rocky mountains, with the single exception of the Arkansas, and a large share of the waters which lie between its own bed and that of the upper Mississippi. The area which it drains is estimated at 519,400 sq. m. Passing as it does through a newly settled country, there are few large cities and towns on its banks; the most important are Omaha City in Nebraska, Atchison and Leavenworth in Kansas, and St. Joseph, Kansas City, Lexington, Booneville, Jefferson City, and St. Charles in Missouri. About 411 m. from its source the river passes through a narrow gorge denominated the "Gates of the Rocky mountains." It is $5\frac{1}{2}$ m. long, and the perpendicular walls of rock, which rise directly from the water to the height of 1,200 feet, are only 450 feet apart. For the first 3 m. there is but one spot where a foothold could be obtained between the water and the rock. The

Great falls occur about 145 m. below this point. They are the grandest on the North American continent after those of Niagara, and consist of 4 cataracts, respectively of 26, 47, 19, and 87 feet perpendicular descent, separated by rapids. The whole fall in $16\frac{1}{2}$ m. is 857 feet.

MISTAKE. The principles of law in relation to mistake are of much practical importance. That which is most general, and may be regarded as fundamental, is, that no man shall avail himself, either to establish or resist a claim, of his mistake or ignorance of law. So also in criminal law it is an ancient maxim: *Ignorantia legis neminem excusat*. The reason sometimes assigned, that the law supposes every one to be acquainted with it, is nothing more than a repetition of the rule in other words. The true reason is, the extreme danger of permitting any person to shelter himself under his ignorance of the law, or to found a right upon it. For this would be, in the words of the king's bench in England, "to hold out a premium for ignorance;" and ignorance of that which it is of the utmost importance that all men should know. Hence the law distinguishes most carefully between a mistake of law and a mistake of fact; for the latter is, as a general rule, rectified, and all mischievous consequences prevented, as far as possible; and a mistake as to the law of a foreign state or country is regarded only as a mistake of fact, because no one is under any obligation to become acquainted with a foreign law.—To this general rule there are some important qualifications; the principal one being, that no mere acknowledgment, or waiver of defence or right, made under a mistake of law, is binding. Thus, if one has a good legal defence against a promissory note, but, by an ignorance or mistake of the law, supposes himself bound to pay it, and on this supposition gives a promise to pay it, the promise will not, in general, be binding upon him. There is also, in many cases, much relief to be obtained by the construction of a contract; but this is always governed and limited by certain definite rules. It is often stated by ethical writers, that a party to a contract is bound to execute the contract in the sense which he knew the other party to put upon it. This may be true always in a moral sense; but it certainly is not true in a legal sense, although courts have sometimes seemed to think it was a good rule of law. The true rule and the reason of it are easily seen. If A contracts with B in writing to sell him 100 mules, and receives the money, and B at the time, being a foreigner perhaps or for some other reason, understood that he was buying horses, all which A knew, nevertheless B could not claim horses under the contract. He could, by proving his mistake and A's knowledge of it, make out a case of fraud, and this would annul the contract, and then he could recover his money from A. But the reason why he could do no more is, that the law will not, under pretence of construing a contract, make a new contract for the parties. Hence, it is another way of ex-

pressing the same rule, that the actual intention of the parties to a contract shall be carried into effect, so far as it is possible to arrive at that intention by a rational construction of the words they have actually used, but no further; for it is one of the most reasonable, safe, and well established rules, that no evidence from without a written contract shall be permitted to control or vary it. While parties are negotiating they may change their minds and vary their demands and concessions, and generally do this to some extent. But when they have finally put their terms in writing, the law supposes that these are what they have concluded upon, and that they have chosen and used the very words which express their meaning; and that whatever is not therein stated, although it may have previously passed between them, has been purposely omitted because it was not finally agreed to. It would therefore be manifestly unjust to permit evidence of any of these things to come forward and vary the written contract; and hence the rule, which is concisely expressed in the Scotch law thus: "Writing cannot be cut down or taken away by the testimony of witnesses." But while evidence must not vary, it may explain, the contract. Thus, in the most solemn deed, it may be necessary to explain the terms of the instrument, in order to show who the parties are, what the boundaries of land mean, or where it is situated. But it is a very different thing when one of the parties says that the deed contains a mistake; that the house or the field it conveys is not the house or field which it was intended to convey; and on this ground demands to hold the house or field which, as he alleges, should have been given to him. And it may be regarded as the established rule concerning mistakes, that any mistake in an instrument may be corrected, if the instrument itself affords the means of correction; but not, if it can be done only by going outside of the instrument. Questions of this kind frequently occur in the construction of wills; and sometimes they present extreme difficulties. Thus, if a legacy is given, and the name of the legatee describes no one perfectly, or is equally applicable to two persons, it is, in the first place, certain, that if any thing else in the will will clear up the question, it will be used for that purpose; and, secondly, that if it is a case of mere obscurity, evidence may be received to clear up that obscurity; but if the case is one which is without any question of itself, evidence cannot be admitted to show that the testator meant something else than that which he has distinctly said, and thus to rectify a mistake. A strong case is cited in the English books, where an attorney employed to draw a will for a sick man, wrote his own name in the place of one whom he was directed to make a legatee of a large sum, and the will was so executed. The facts being proved, the intended legatee claimed the legacy, by correction of the mistake into which the attorney had led the testator. But it was held that this was impossible by the rules of

law. Then, however, a court of equity decreed that the attorney should take the legacy, but only as a trustee for the intended legatee, and immediately pay it over to him. This must be regarded rather as suppressing a fraud, and establishing and enforcing an equitable trust, than as an exercise of the equity power of correcting a mistake; for the extensive and very beneficial power which a court of equity has in case of mistake is exercised in general between parties to an instrument. (See CHANCERY, and EQUITY.)

MISTLETOE, or **MISSLETOE** (*viscum* or *viscum*), a common mistletoe or mistelden), a parasitic plant belonging to a genus embracing 76 species (Don), of which number this is the only one found in Europe. The word is supposed by some to be derived from the German *Mist*, dirt; or slimy dirt; by others from *mistella*, a Saxon for the plant. The berries, which are usually white, secrete a slimy juice, and are used in making bird lime; whence *viscum* in Latin and *ifos* in Greek signify both mistletoe and bird lime. The mistletoe belongs to the natural order *loranthaceæ*, evergreen shrubs, with forked-branched stems, parasitically implanting themselves in the woody portions of various trees, sometimes insinuating themselves by creeping roots under the bark, and sometimes growing in the ground. The flowers of some of the species are imperfect, small, inconspicuous, white or greenish yellow; of others they are perfect, beautifully colored, very showily variously diffused over the plants, and frequently having from one to many bracts. Most of the order occur in tropical regions, a few being found elsewhere. The common mistletoe is found in England, and is familiarly known there on account of various customs, traditions, and superstitions connected with it. It is an evergreen bush attached to the trunk and branches of trees, composed of dense numerous shoots, opposite leaves, and yellow flowers, which are succeeded by fruit which is most always white, but there is said to be a variety with red fruit. The plant is sometimes more than 8 or 4 feet in diameter; it is crowded with branches and leaves. Its growth is slow, seldom more than 2 or 3 inches of shoot and 2 or 3 pairs of leaves being produced in a season. The leaves vary considerably in different plants. The durability of the plant is proportionally great, for when once established on a tree it is seldom known to cease growing while the tree lives.—The mistletoe is commonly propagated by its berries being removed and adhere by some means or other to the trunk of a living tree. It is supposed that birds which feed upon these berries wipe off some of the seeds which adhere to their bills by rubbing them against the bark. We are informed by an eye witness that in a similar manner the seeds of orchidaceous epiphytes are deposited on trees, and even on other and dead vegetable productions by the birds which feed upon the fruits. In the cold parts of South America, where these did vegetable productions abound in the forest

Such seeds soon vegetate, and even put forth a few leaves, but perish unless lodged upon living trees or in appropriate places. Ray suggested the experiment of artificially planting the berries of the mistletoe in or upon the smooth bark, and the trial succeeded. In 1838 Mr. Baxter, of the Oxford botanic garden, England, rubbed 9 mistletoe seeds on the smooth bark of an apple tree, all of which germinated. Duhamel succeeded in making them sprout upon other substances, such as bricks, tiles, stones, the ground, &c., but the plants did not long survive. It is a well known law in vegetation that the young root or radicle, as it protrudes from the seed, seeks to descend and plunge itself deeply in the soil; but it has been ascertained that in the seed of the mistletoe the radicle invariably turns itself toward the surface of the body to which the seed has been affixed; so that it happens that sometimes the young root has first to raise itself up and then bend over until it reaches the surface of the bark or other substance. Having done so, the point of the radicle swells out into a sort of disk, the better to attach itself. Generally a single radicle belongs to a seed, especially if the seed be of an oval form; but if it is triangular or irregular, 2, 3, or more appear. Seeds artificially attached to a cannon ball, suspended by a cord at some distance from the earth, were found to direct their radicles to the surface of the ball, whether they were on the upper or lower surface or upon the sides. This peculiarity secures their growth upon every surface of the branches of trees. A seeming explanation has been proposed by supposing that the radicle seeks to avoid the light; and Dutrochet found, indeed, that when he glued the seeds upon the inside or upon the outside of the panes of a window, in each case the young roots were found to be seeking the interior of the room. The facility of thus growing under any circumstances upon the trees which the plant affects, determines somewhat the future size and shape; as for instance, when the germination occurs upon the upper side of a branch, the shoots bend upward; but if it occurs on the under side, the shoots descend; and if, again, the shoots start on the side of a perpendicular trunk, they proceed to grow horizontally, spreading of course with the growth of the plant so as to ultimately form a hemispherical bush. The roots of the mistletoe which penetrate the bark extend themselves between the inner bark and the soft wood, where the sap is most abundant, sometimes sending up suckers at a distance from the point where the roots entered. These roots after a while become imbedded in the solid wood, and hence has arisen the opinion that the mistletoe actually roots itself into the solid wood as well as into the living bark; which would be very unlikely, as no nutriment, such as it wants, could be drawn from thence. It is generally admitted, too, that the mistletoe robs the branch of its ascending and descending sap, and thus is inju-

rious in its presence; hence in orchards it is customary to remove it as soon as it appears. —Several kinds of birds eat the berries; they are the favorite food of the missel thrush. As a medicine the plant was once considered valuable in the treatment of epilepsy, and the Romans prized it as an antidote to poisons. Its principal use now is to hang up with holly in rooms at Christmas. The custom of kissing under it at that festive season is referred to the supposition on the part of some that it was the forbidden tree in the garden of Eden. This pleasant Christmas custom Mr. Loudon supposes most likely came from our Saxon ancestors, and to have been commemorative of Baldur the son of Odin. In the feudal ages, the same writer adds, it was gathered with great solemnity on Christmas eve and hung up in the great hall with loud shouts and rejoicings. Among the druids the mistletoe was considered sacred if found growing upon the oak, and was possibly rendered thus valuable from its rarity; for its appearance on that tree is now so rare that the druids' mistletoe is conjectured by some to have been some other plant. The tradition is, that it was cut from the oak with great ceremonies on the first day of the new year, and at that time consecrated to their chief deity on account of the extraordinary virtues they attributed to it. Pliny, among other ancient writers, gives a similar account. It was also used in religious ceremonies by the Persian magi.—The representative of the mistletoe in the western and southern portions of the United States is *phoradendron flavescens* of Nuttall, which grows chiefly upon the branches of elms and hickories; a yellowish green, woody-stemmed parasite, with a jointed stalk having opposite and whorled branches, fleshy, obovate-shaped leaves, small flowers in axillary spikes, which are shorter than the leaves, and fruit of white, glutinous berries. (Chapman's "Flora of the Southern United States," New York, 1860.) This species has a wide distribution from New Jersey westward, and southward to Mississippi and Florida. A botanical exploration of New Mexico in 1846, by Mr. Augustus Fendler, enabled Dr. Engelmann and Prof. Asa Gray, at whose suggestion and with the assistance of the secretary of war it was undertaken, to arrange and describe other American mistletoes. This arrangement can be found in the "Memoirs of the American Academy," new series, vol. iv. p. 58 (Cambridge and Boston, 1849), where 6 species of *phoradendron* are noticed, including the present and the *P. Californicum*, with the *P. tomentosum* (De Candolle), the others being new. An allied genus, *arcanthobium* (M. Bieb.), comprises two species, viz.: the *A. oxycedri*, parasitic on the *pinus edulis*, which grows on the mountain sides around Santa Fé, and the *A. cryptopodon* (Engelm.), parasitic on the *pinus brachyptera*, which grows in western New Mexico. For further information on these American forms, consult the "Reports of Explorations and Surveys for a Railroad Route to the Pacific," vol. iv. p. 184.

MITAU, or MITTAU (Russ. *Mitavo*; Lettish, *Yelgava*), a town of European Russia, capital of Courland, in a low marshy district adjoining the Aa, 25 m. S. W. from Riga; pop. in 1852, 18,819, chiefly Germans, including many Jews. The principal public edifices are the castle, once the residence of the dukes of Courland, the Greek, Catholic, and Protestant churches, &c. Linens and hosiery are manufactured. Louis XVIII. and his court chiefly resided there from 1798 to 1807.

MITCHEL, a N. co. of Iowa, intersected by the Red Cedar river and its east fork; area, 481 sq. m.; pop. in 1859, 8,291. The productions in 1859 were 15,879 bushels of wheat, 28,487 of oats, 43,830 of corn, 12,436 of potatoes, 51,680 lbs. of butter, and 4,188 tons of hay. It has been but recently settled.

MITCHEL, JOHN, an Irish revolutionist, born Nov. 8, 1815, in the town of Dungiven, county of Derry, where his father officiated as a minister of the Unitarian persuasion. He was graduated at Trinity college, Dublin, in 1836, studied law, and practised his profession for 6 years in Newry and Banbridge, during the stormy period of O'Connell's "monster meetings," his arrest, trial, and imprisonment. In 1845, on the death of Thomas Davis, the colleague of Mr. Gavan Duffy in the "Nation," Mitchel was called to Dublin to succeed him. His articles were revolutionary in spirit, and for one which appeared in 1846, showing how the people could contend with the army, and advocating the use of vitriol against the troops in case of a conflict in the streets, the "Nation" was prosecuted by government. In consequence of the pruning to which his articles were subsequently subjected, he quarrelled with Duffy toward the end of 1847, and soon after founded "The United Irishman," an organ which teemed with legal treason, and brought him in direct collision with the government. After an existence of 8 months the journal was suppressed, and its editor sentenced to expatriation for the term of 14 years. On May 27, 1848, after two weeks' incarceration at Newgate, Mr. Mitchel was taken in irons from Dublin to the convict depot of Spike island (Cork harbor), where a government order was received to treat him "as a person of education and a gentleman." Taken thence in a day or two, on the Scourge sloop of war, he passed 10 months of his sentence in the island of Bermuda, whence he was again deported to Australia. Here he met Messrs. Smith O'Brien, Meagher, Martin, and other political associates whom he had left behind in Ireland, but who had met the same fate and were there before him. On July 19, 1854, Mr. Mitchel resigned his parole and effected his escape from the colony, landing in New York on Nov. 29. There he founded the "Citizen," a weekly journal, which he conducted for some time until failing eyesight constrained him to seek a more congenial climate. He removed to Tennessee, where he subsequently established the "South-

ern Citizen," in which among other measures he advocated the reopening of the African slave trade. This journal was afterward removed to Washington, and in 1859 ceased to appear. After its suspension Mr. Mitchel spent some time in France, but has since returned to the United States. He is the author of "Hug. O'Neill" and his own "Jail Journal," in which he details the events of his imprisonment. He has also edited the poems of Thomas Davis and James Clarence Mangan, with biographies of both.

MITCHEL, ORMSBY MACKNIGHT, an American astronomer, born in Union co., Ky., Aug. 2, 1810. At 12 years of age, with a good knowledge of Latin and Greek and the elements of mathematics, he commenced the world for himself as clerk in a store in Miami, O., and afterward removed to Lebanon, Warren co., where he had been educated. There he received a cadet's warrant, and earned the money that took him to West Point, which place he reached with a knapsack on his back and 25 cents in his pocket, in June, 1825. On graduating in 1829 he was made acting assistant professor of mathematics, which post he held for two years. From 1832 to 1834 he was counsellor at law in Cincinnati, O.; from 1834 to 1844 professor of mathematics, philosophy, and astronomy at Cincinnati college; in 1836 and 1837 chief engineer of the Little Miami railroad; and in 1841 member of the board of visitors of the military academy. In 1845, at the close of a course of lectures on astronomy in Cincinnati, he proposed the establishment of an observatory at that place; and the proposition having been at once carried out, mainly by his own exertions, he became director of the institution. The ground for the building was given by Nicholas Longworth, Esq. The building is of stone, 80 feet length and 2½ stories high. The principal instrument is the great refractor equatorially mounted and made by Merz and Mohler of Munich. It cost \$10,000, which Prof. Mitchel sustained by subscriptions, mostly of \$25 each, in Cincinnati. In 1859 he became director of the Dudley observatory at Albany, retaining at the same time his connection with that at Cincinnati. Prof. Mitchel is eminent as a popular lecturer on astronomy, and scarcely less distinguished for his mechanical skill, by the apparatus which he has perfected a variety of apparatus of great use to astronomy. One of the most important of his constructions is an apparatus at Albany for recording right ascensions and declinations by electro-magnetic aid to within 1/100 of a second of time, and for the measurement with great accuracy of large differences of declination, such as the ordinary method with a micrometer cannot at all reach. Prof. Mitchel has carefully investigated the velocity of the magnetic current. Among his discoveries is the exact period of rotation of Mars, and the companion of Antares or Cor Scorpii. His most popular and characteristic of his publications is "Planetary and Stellar Wonders."

collection of earlier public lectures. He is the author also of a treatise on algebra, and of a "Popular Astronomy." In July, 1846, he published the first number of the "Sidereal Messenger," the first periodical attempted in the United States devoted exclusively to astronomy. About the end of the second year it was abandoned for want of patronage. Prof. Mitchel has devoted much time to the remeasurement of Prof. W. Struve's double stars south of the equator. The work was undertaken at the special request of that astronomer, and has resulted in a number of interesting discoveries.

MITCHELL, DONALD GRANT, an American author, born in Norwich, Conn., in April, 1822. He was graduated at Yale college in 1841, and after passing 8 years on a farm for the benefit of his health, during which time he corresponded on agricultural topics with the "Albany Cultivator," he travelled extensively in Europe. Returning home in 1846, he commenced the study of the law in New York, and in 1847 published, under the pseudonyme of "Ik Marvel," which he had employed as a newspaper correspondent, a volume entitled "Fresh Gleanings, or a New Sheaf from the Old Fields of Continental Europe," embracing his reminiscences of European travel. He soon after returned to Europe, and passed several of the most eventful months of 1848 in Paris and its environs, recording his experiences in "The Battle Summer" (New York, 1849). This was succeeded by a satirical work entitled "The Lorgnette," which appeared in numbers and anonymously, and was subsequently published in 2 vols. (1850). In the same year also appeared "The Reveries of a Bachelor," his most popular work, and in 1851 his "Dream Life." In 1853 he received the appointment of U. S. consul at Venice, and after holding that office a short time made another continental tour, and in 1855 returned to America. He has since resided on his farm in the neighborhood of New Haven. His last publication is "Fudge Doings" (2 vols. 12mo., 1854), a satire upon fashionable life in America, originally contributed to the "Knickerbocker Magazine." He has also delivered several agricultural addresses and lyceum lectures; and has long been engaged in writing a history of the republic of Venice.

MITCHELL, ELISHA, D.D., an American chemist and professor, born in Washington, Litchfield co., Conn., Aug. 19, 1798, lost his life on the Black mountain in North Carolina, June 27, 1857. He was graduated at Yale college in 1818, served there some time as a tutor, and in 1817 was elected professor of mathematics in the university of North Carolina, and entered on the duties of that office at the close of 1818. In 1825 he was transferred to the chair of chemistry, which he held during the rest of his life, giving instruction also in the various branches of natural history. In 1821 he was ordained by the presbytery of Orange, and was an able preacher and biblical scholar. He was for some time the state surveyor, and

made a careful geological and topographical exploration of its territory. He first ascertained that the mountains of North Carolina are the highest east of the Rocky mountains; and his name has for many years been given to what was thought their loftiest summit. It was to settle some disputed points in regard to these heights, that he ascended them once more in 1857, when, having lost his way at night, he fell down a precipice into a pool that feeds the Sugar Camp fork of Caney river, and was found there lifeless. His remains were interred on the topmost height of the mountain that bears his name. Dr. Mitchell published little, except in the "American Journal of Science" and the newspapers, though he printed a few controversial tracts, a treatise on geology, and one on chemistry, for the use of his own classes.

MITCHELL, JOHN KEARSLEY, M.D., an American physician, born in Shepherdstown, Jefferson co., Va., May 12, 1796, died in Philadelphia, April 4, 1858. His father, a physician of Scotch birth, sent him at the age of 8 years to be educated in Scotland. In 1818 he returned home, began the study of medicine with Dr. Kramer of Jefferson co., Va., and in 1819 was graduated at the university of Pennsylvania. After making three voyages to China in the capacity of surgeon to merchant ships, he settled in Philadelphia in 1822, and began to practise medicine and to teach physiology. In 1824 he lectured on the institutes of medicine and physiology in the Philadelphia medical institute. Two years later he accepted the chair of chemistry in the same school, and in 1833 was selected to lecture in the Franklin institute on chemistry applied to the arts. In the spring of 1841 he was called to the chair of the theory and practice of medicine in the Jefferson medical college of Philadelphia. At different times he was one of the physicians to the Pennsylvania hospital and to the city hospital. His services during seasons of pestilence were twice rewarded by municipal gifts. Beside a volume of poetry entitled "Indecision, and other Poems" (Philadelphia, 1839), and popular lectures on scientific subjects which were translated into several foreign languages, he left a work "On the Cryptogamous Origin of Malarious and Epidemical Fevers" (1849), and many valuable contributions to the "American Journal of the Medical and Physical Sciences." A collection of some of his essays, including a valuable paper on animal magnetism, was published in Philadelphia in 1858.

MITCHELL, MARIA, an American astronomer, born in Nantucket, Aug. 1, 1818. She is by birth and education a member of the society of Friends, and at the age of 11 entered a school kept by her father, partly as student and partly as assistant teacher. From the same parent, who was devoted to the study and practice of astronomy, she derived a fondness for that science; and by her intelligence in the use of instruments and her mathematical attainments, she soon became an enthusiastic coöperator in the observations carried on by him. Sub-

sequently she made many careful observations by herself, and devoted much time to the examination of nebulae and the search for comets. On Oct. 1, 1847, while engaged in this latter occupation, she discovered a telescopic comet, which was seen on the 3d at Rome by Father da Vico, and subsequently by other astronomers, and for which she received a gold medal from the king of Denmark. The elements of this comet were calculated by her and communicated to the Smithsonian institution; and she was afterward employed in observations connected with the coast survey and in the compilation of the nautical almanac authorized by government. Miss Mitchell is still diligently engaged in astronomical pursuits, having at her command for that purpose a well appointed observatory and the latest mathematical and scientific works, and is a regular attendant upon the meetings of the American association for the advancement of science, of which she was chosen a member on the nomination of Professor Agassiz. She is also a member of the American academy of arts and sciences, being the first female admitted into that body.

MITCHELL, THOMAS, an English scholar and philologist, born in London, May 30, 1783, died near Woodstock, May 6, 1845. He was the son of a riding master, and was graduated at Pembroke college, Cambridge, in 1806. A few years after he obtained a fellowship in Sidney Sussex college, but lost it after a limited time from his unwillingness to enter holy orders. He then engaged in private teaching and in writing for the press; and a series of essays by him in the "Quarterly Review," on Aristophanes and Athenian manners, commenced in 1813, was followed in 1820-'22 by a metrical translation of some of the plays of Aristophanes (2 vols. 8vo.). Rejecting, though without fixed means of support, an offer of a Greek professorship in Scotland, from repugnance to signing the confession of the Scottish kirk, he was employed at intervals for several years in editing Greek works printed at Oxford. He published in 1834-'8, in separate volumes, 5 of the plays of Aristophanes, with English notes; and afterward a complete edition of Sophocles, on the same plan, the first volumes of which were not well received, and which he was enabled to finish by a present, through Sir Robert Peel, of £150 from the royal bounty fund.

MITCHELL, SIR THOMAS LIVINGSTONE, a British engineer, born in Stirlingshire, Scotland, in 1792, died near Sydney, Australia, Oct. 5, 1855. He joined the British army in Spain in 1808, and attained the rank of major, and was afterward employed in making surveys and military maps of the peninsular battle fields. In 1827 he was appointed deputy surveyor-general of eastern Australia, and ultimately surveyor-general, which office he held till his death. He conducted 4 remarkably successful expeditions into the interior of the Australian continent, the first of which, in 1831-'2, resulted in the discovery of the Peel and Nammoey rivers; and

during the 2d and 3d, in 1835-'6, the Darling and Glenelg rivers were explored, and Australia Felix discovered. The 4th, commenced in Dec. 1845, and finished in Dec. 1846, was undertaken to trace out a route from Sydney to the gulf of Carpentaria; the loss of their cattle and horses prevented the explorers from completing the expedition, but they discovered the Victoria river. In the interval between the 3d and 4th expeditions Major Mitchell visited England, and published a narrative under the title of "Three Expeditions into the Interior of Eastern Australia, with Descriptions of the recently explored Region of Australia Felix," &c. (2 vols. 8vo. London, 1838). His account of the last expedition appeared in 1848, under the title of "Journal of an Expedition into the Interior of Tropical Australia." In 1853 he again repaired to England, and delivered a lecture, which was published, on the boomerang propeller, which he had invented, for steam vessels. He was knighted in 1839, and made a colonel in 1854. Oxford university conferred on him the honorary degree of D.C.L.

MITCHELL'S PEAK. See BLACK MOUNTAIN.

MITCHILL, SAMUEL LATHAM, M.D., LL.D., an American physician, born in North Hempstead, Long island, Aug. 20, 1764, died in New York, Sept. 7, 1831. He was graduated as M.D. at the university of Edinburgh in 1786, and returning to America the next year, devoted some time to the study of law under Chief Justice Yates of New York. In 1788 he was a commissioner for treating with the Iroquois Indians for the purchase of land; in 1790 he was a representative from Queen's county in the state legislature; and in 1792 he was appointed professor of chemistry, natural history, and philosophy in Columbia college, where he first introduced the system of nomenclature invented by Lavoisier. His dissent from some of Lavoisier's principles involved him in a controversy with Dr. Priestley, which was conducted with remarkable good temper and led to a lasting friendship between the two disputants. In 1793-'4 Dr. Mitchill founded, with Chancellor Livingston and Simeon De Witt, the society for the promotion of agriculture, manufactures, and the useful arts, at the request of which he made a geological and mineralogical tour along the banks of the Hudson (1796), presenting the results of his observations in a report which established his reputation at home and in Europe. In the following year he began, in conjunction with Dr. Edward Miller and Elihu B. Smith, the quarterly "Medical Repository," of which he continued the editor for 16 years. It was the first scientific periodical published in the United States. About the same time he was elected a member of the legislature by the city of New York. In 1801 he became a representative in congress, and in 1804 was chosen to the U. S. senate. At the expiration of his term of office he was again elected to the house of representatives. On the establishment of

college of physicians and surgeons (1807) he was appointed to the chair of chemistry, which his other duties induced him to decline; but in the following year he accepted the professorship of natural history, retaining it until the reorganization of the college in 1820, when he became professor of botany and materia medica. The institution was broken up in 1826 by the retirement of the whole faculty, and gave place to the Rutgers medical school, of which Dr. Mitchill became vice-president. His death was caused by a pneumonic disease of a few days' duration. Though widely respected in his lifetime as a man of extraordinary learning, Dr. Mitchill was occasionally the victim of the satirical wits of New York, and the poems of "Croaker and co.," to which Fitz-Greene Halleck was a contributor, contain records of some of his eccentricities. He proposed to change the name of this country to "Fredonia," and wrote in 1804 "An Address to the Freedes, or People of the United States." He was one of the early supporters of Robert Fulton, whom he accompanied in 1807 in the first steamboat journey on the Hudson. He was the author of "Observations on the Absorbent Tubes of Animal Bodies" (12mo., New York, 1787); "Nomenclature of the New Chemistry" (1794); "Present State of Learning in the College of New York" (1794); "Life, Exploits, and Precepts of Tammany, the famous Indian Chief," a half historical, half fanciful address before the Tammany Society of New York (1795); "Synopsis of Chemical Nomenclature and Arrangement" (1801); and various addresses, &c., beside a number of valuable papers in the transactions of several learned societies.—See "Reminiscences of Samuel Latham Mitchill, M.D., LL.D.," by John W. Francis, M.D. (New York, 1859).

MITE, a name applied to many very small articulated animals, of the arachnoid order and sub-order *acarina*, including the ticks, itch insects, and other parasites, and the minute acari. The abdomen is unarticulated, and fused with the cephalothorax; the external envelope is of chitine, solid and indestructible; 4 pairs of feet on the cephalothorax, armed with nails, and in some provided with long pedunculated disks by which the animal is attached; some, when young, have 6 feet; eyes usually absent; mandibles wanting, the antennæ being changed into prehensile and masticatory organs, moving vertically, piercing or cutting as may be necessary, and sometimes enclosed in a sheath in the form of a sucker. The stomach has several cæcal appendages, and the short and straight intestine opens near the middle of the abdomen; salivary glands well developed; no apparent heart nor blood vessels, the colorless nutritive fluid filling all the interstices of the body, and being irregularly circulated by the muscular movements and the contractions of the intestinal canal; respiration aerial, performed chiefly by the skin, and in some by tracheæ. The sexes are separate; many have an ovipositor, by which they insert their eggs under the

epidermis of plants and animals, in the latter case often causing great irritation; some surround their eggs by a tough substance which glues them to various objects. Their extreme minuteness in some cases may be judged of by the fact that they infest flies and very small insects; they are exceedingly prolific. Some live under stones, others on plants, on animals, or among decaying organic substances, and a few are aquatic; the parasitic ones, sucking the blood of animals and man, are sometimes very annoying, as the experience of most travellers and woodsmen testifies. The itch insect has been described under *ITCH*, and the ticks and other mites under *EPIZOA*. Among the mites, the *acarus domesticus* is found especially in old cheese (the powder of which, so agreeable to epicures, is made up of these little animals with their eggs and excrement), in flour, sugar, and on figs and sugared fruits; the *A. destructor* feeds upon the specimens of the entomologist and zoologist; the garden mites (*trombididae*) live upon fruits, flowers, and leaves; the spider mites (*gamasida*) include the minute red spider of hothouses; and the wood mites (*oribatida*) creep among stones and moss.

MITFORD, MARY RUSSELL, an English authoress, born in Alresford, Hampshire, Dec. 16, 1786, died near Reading, Jan. 10, 1855. She was the daughter of a physician, a man of a singularly amiable temperament and engaging manners, but whose speculative tendencies early involved his family in ruin. Her education was chiefly acquired at a school in Chelsea, where she had for her governess out of school hours a Miss Rowden, who had previously taught Lady Caroline Lamb, and who afterward instructed Miss Landon and Fanny Kemble. At 20 years of age she published 8 volumes of poems, some of them long narratives in the style of Scott; they were roughly criticized by the "Quarterly Review." About 1812 she adopted literature as a profession, being prompted thereto by the embarrassed pecuniary circumstances of her father, and for several years was an industrious contributor of tales and sketches to the magazines and annuals. The example of Irving's "Sketch Book" first suggested to her the idea of writing sketches of the daily life of the rural population, and her most popular work is "Our Village," the scene of which is laid at the little hamlet of Three Mile Cross, near Reading. The sketches passing under this title, after having been refused admission to the "New Monthly Magazine," then edited by Thomas Campbell, were first published in the "Lady's Magazine" about 1820. The cheerful tone of kindness and domesticity pervading them, their mingled humor and pathos, and the simple and yet finished style in which they were written, insured them success; and the authoress extended her sketches to 5 volumes or series, the last of which appeared in 1832. In a similar vein was written "Belford Regis," for which the neighboring town of Reading supplied the materials. Among her other prose works were a volume of "Coun-

try Stories," which formed the 89th volume of the "Parlor Library," and several of the "Edinburgh Tales" published by Mrs. Johnstone in 1845. She also edited 8 volumes of "Stories of American Life by American Authors," and 4 of the annual volumes of Finden's "Tableaux." Her dramas, "Julian" (1823), "Foscari" (1826), "Rienzi" (1828), and "Charles the First," were performed with a considerable degree of success, "Rienzi" being on the whole the most popular. Her "Charles the First" was prohibited by George Colman, the licenser, for its supposed dangerous revolutionary sentiments, but was finally produced at the Coburg theatre in London. She also wrote several other dramas, which were never acted, and an opera, "Sadak and Kalasrade," the music of which was written by Packer. Among the closing events of her literary career was the publication of her "Recollections of a Literary Life" (8 vols. 12mo., 1852), a book "full of delightful reading, and furnishing the best illustrations of the writer's taste and character." Her last work was "Atherton and other Tales" (8 vols. 8vo., 1854). For upward of 40 years she lived in a little cottage in Berkshire, surrounded by the scenes so graphically described in "Our Village," the delight of the social circle in which she moved, and beloved by her rustic neighbors. About 8 years before her death an accident caused by the overturning of her pony chaise greatly enfeebled her, and the remainder of her life was passed in much physical suffering, but with characteristic cheerfulness.

MITFORD, WILLIAM, an English historian, born in London, Feb. 10, 1744, died in Hampshire, Feb. 8, 1827. He entered Queen's college, Oxford, where he proved a very indifferent scholar in every thing but Greek. Leaving the university without a degree, he studied for a while at the Middle Temple, but soon tired of the law, and abandoning the profession to his younger brother, who afterward became Lord Redesdale, retired to his ancestral estate in Hampshire, married, and devoted himself to literature. His early fondness for Greek led him to the study of the old historians of that nation; and with the advice of Gibbon, who was a fellow officer in the Hampshire militia, he resolved to undertake a history of Greece, the 1st volume of which appeared in 1784, and the 5th and last in 1818, bringing the narrative down to the death of Alexander the Great. Mr. Mitford was prevented by age and failing eyesight from carrying on the work, as he had intended, to the period of the Roman conquest. With considerable critical acumen and learned research, he succeeded in elucidating many obscure points, and until the publications of Thirlwall and Grote was esteemed the highest authority on the subjects of which he treats. His worst faults are a strong prejudice against democracy, which often distorts his judgments, lack of philosophic reflection, dulness of narrative, and cumbrousness of style. An edition of

his work by Lord Redesdale, with an introduction, appeared in 1829 (8 vols. 8vo.), and it has frequently been reprinted. Mr. Mitford also published a treatise on the religions of ancient Greece and Rome, as a supplement to his history; "An Inquiry into the Principles of Harmony in Languages and of the Mechanisms of Verse, Modern and Ancient" (1774); and a "Treatise on the Military Force, and particularly the Militia, of this Kingdom." Beside commissions in the militia, he held several public offices, being county magistrate, verdurer of the New forest, and professor of ancient history in the royal academy. He was a member of parliament for Newport in Cornwall from 1785 to 1790, for Beeralston from 1796 to 1806, and for New Romney from 1812 to 1818.

MITHRA. See MYSTERIES.

MITHRIDATES, or MITHRADATES, a king of Pontus, the 6th of the name, surnamed *ΕΥΡΥΤΗΣ* and *THE GREAT*, born in 186, died in 68 B. C. He ascended the throne in 120. He subjugated the barbarians between the Euxine and the Caspian, extended his conquests among the tribes beyond the Caucasus, rendered the Tauric Chersonese tributary, and on the demise of Pharnaces king of the Bosphorus, annexed that country to his dominions. He next expelled the kings of Cappadocia and Bithynia, dependent allies of Rome, from their dominions, but the Romans presently restored them. Nicomedes the Bithynian was not content with recovering his kingdom, and invaded the dominions of Mithridates, who, failing to obtain redress from Rome, immediately commenced hostilities against her generals and allies. In 88 he again expelled the Cappadocian and Bithynian sovereigns, defeated the Roman armies that attempted to support them, made himself master of Phrygia and Galatia, overran the whole Roman province of Asia, and ordered all the Roman citizens found within its borders to be massacred; the victims of this decree are said to have numbered over 80,000. When these things were known at Rome, Sylla was appointed to command the armies sent against Mithridates, who transferred the seat of war to Greece, where his general Archelaus suffered two great defeats at Thermopylae and Orchomenus in 86, while Mithridates was himself defeated in Asia by Fimbria. He was in consequence constrained to abandon his conquests in Asia, to pay an indemnity of 2,000 talents, and to surrender all his ships to the Romans (84). The events of what is called the second Mithridatic war are not of much interest; but the death of Nicomedes III, king of Bithynia, in 74 was the signal for the outbreak of the third. That monarch had bequeathed his dominions to the Roman people, and Bithynia was pronounced by the senate a Roman province. Mithridates refused to recognize it as such, and attempted by force of arms to place a pretended son of the deceased king on the throne. Entering Bithynia at the head of an army of over 120,000 foot and 16,000 horse, he vanquished the consul Cotta under the walls

of Chalcedon, and then proceeded to lay siege to Cyzicus; but he was eventually compelled by Lucullus, who had been appointed to the chief command in this war, to retreat with great loss into Pontus, whither his adversary presently pursued him. After completely defeating another vast army, Lucullus drove Mithridates from his kingdom. The subsequent mutiny of the Roman legions, however, enabled the indomitable oriental to recover Pontus. In 66 Lucullus was superseded by Pompey, and the war was resumed. Mithridates was surprised and totally defeated, and, to avoid captivity, plunged at the head of a handful of troops into the savage regions N. of the Euxine, and made his way to Panticapæum, the capital of the Cimmerian Bosphorus. Here he was safe from the Romans; but while he was planning schemes of aggression against Rome his son Pharnaces openly rebelled, and was proclaimed king by the soldiers and citizens. Mithridates, on learning this, took refuge in a strong tower, where, seeing no alternative save death or slavery, he sought to end his life by poison; but this proving ineffectual, he ordered one of his Gallic mercenaries to despatch him with his sword. It is said that to avoid being poisoned, to which he was much exposed during the vicissitudes of his career, he had accustomed himself to the use of antidotes to such a degree that the most painful drugs had little effect on him. His son sent his body to Amisus as a peace offering to Pompey; but the Roman general caused it to be interred with regal honors in the sepulchre of the Pontic kings at Sinope. Mithridates possessed a powerful memory, was well acquainted with Greek literature, and understood more than 20 languages which were spoken in his dominions.

MITRE (Gr. *μῦρα*), an ornament worn upon the head by archbishops and bishops in the Roman Catholic and Greek churches, and also by abbots of certain orders. It consists of a stiff cleft cap, rising in two points, one before and the other behind, and having two ribbon-like pendants which fall upon the shoulders. It is often very richly adorned with gold and jewels. It was borrowed from the *mitenepheth* of the Jewish high priests, which was copied from the mitre made for Aaron (Exod. xxviii.). Upon the forefront of Aaron's mitre, over a blue lace, was a plate of pure gold, and graven upon it, "like the engravings of a signet, Holiness to the Lord." We find, however, in various nations of antiquity, caps resembling the modern mitre, from which the latter is sometimes thought to be derived. Bacchus was often represented with a mitre, from which the Greeks gave him the surname of *μυροφάρος*. The Persian deity Mithra appears with a similar head covering, and it has also been traced in India and Egypt. The mitre seems at one time to have been common to both sexes, and afterward restricted to women. It was worn by virgins who embraced a religious life in Africa in the 4th century and in Spain in the 8th, and

something which much resembles it is still in use by the women of Syria and Arabia. Concerning its adoption by Christian bishops there is great diversity of opinion. According to some Roman Catholic writers, it was not known in the West until the 10th century, though introduced much earlier into the East; but Martenne and others hold that it has always been a part of the episcopal costume, though in the early ages bishops did not wear it without special permission from the pope. From the time of Leo IX. (1049) until that of Innocent IV. the mitre was worn by cardinals, who exchanged it for the red hat at the council of Lyons in 1245. Mitred abbots are those who exercise quasi-episcopal authority over their monasteries. Their mitres differ from those of bishops, having the points at the sides instead of in front and behind.

MITSCHERLICH, ERNST, a German chemist, born in Neuende, near Jever, in the grand duchy of Oldenburg, Jan. 7, 1794. He studied at the gymnasium of Jever, where his teacher, the historian Schlosser, excited his interest in oriental history and philology. He pursued his studies especially in this department at the university of Heidelberg (1811), in Paris (1813), and in Göttingen (1814), where he published the first part of a work on a tribe of the East, entitled *Mirchondi Historia Thaheridarum* (1815). Meantime he had turned his attention to the natural sciences, and in 1818 he went to Berlin to devote himself particularly to chemistry. There he discovered the law of isomorphism, the importance of which and the genius of the young chemist were at once discerned by Berzelius on a visit to Berlin in 1819. At his invitation Mitscherlich accompanied him to Stockholm, and passed two years in his laboratory. On his return to Berlin, he became the successor of Klaproth in the academy of sciences and in the chair of chemistry in the university. His first results in the discovery of isomorphism were presented to the Berlin academy in 1819, and in the following year they were generally known and accepted by chemists. His theory treats of the relation between the crystalline form and the atomic elements of substances. He found that bodies of wholly different chemical composition crystallize into cubes, octahedrons, or other forms that entirely coincide in their angular measurements; that their respective elements may supplant each other in compounds without change of the crystalline form; and he therefore inferred that the latter does not depend upon the chemical nature of atoms, but only upon their number and the order in which they are grouped. The bodies which have elements thus chemically unlike but mechanically similar are termed isomorphous. This view of the molecular constitution of bodies, which is one of the most important principles in theoretical chemistry, was not only stated, but has been developed by him in a long series of observations, memoirs of which have appeared in scientific publications. It gave new chemical significance to crystallography, and introduced

a thorough reform into the classification of minerals from a chemical point of view. In 1828 he completed the theory by the discovery that some substances, as sulphur and carbon, under different circumstances, crystallize in two dissimilar forms. Such bodies are termed dimorphous. The reports of his investigations and discoveries are chiefly contained in a large number of papers in the *Abhandlungen* of the Berlin academy and in the *Annalen* of Poggendorf. He has also published a *Lehrbuch der Chemie* (Berlin, 1829-'40; 5th ed., 1858), remarkable for precision and elegance of style, and specially designed to withdraw students from the extreme synthetical tendencies of Schelling's philosophy of nature, and to make them exact and cautious observers. His university lectures had the same object in view, and the illustrative experiments were made with so simple an apparatus that they could be easily repeated privately by the students. He also perfected the instruments for measuring the angles of crystals, and by the aid of a new goniometer answered an objection which had been raised against the isomorphism of crystals from the occasional inequality of the corresponding angles. He proved that such anomalies are not rare even in crystals of the same chemical composition. His researches have extended to the influence of heat on crystallization, have proved the identity of natural and artificial crystals, have obtained important results with reference to the identity or analogy of organic and inorganic substances, and by observing the melting point of rocks have furnished valuable elements to geognosy. Many instruments of his invention have been generally adopted in Germany and other countries; his discovery of isomorphism was rewarded by the gold medal of the royal society of London; and he is one of the few foreign associate members of the institute of France.

MITTAU. See MITAU.

MITTERMAIER, KARL JOSEPH ANTON, a German jurist and statesman, born in Munich, Aug. 5, 1787. He studied at Landshut and Heidelberg, officiated for many years as professor in the former university, and in 1819 removed to Bonn. In 1821 he was invited to fill the chair of jurisprudence at Heidelberg, and, with the exception of occasional absences, he has since presided there over that branch of study; and by his teaching as well as by his writings he has gained the reputation of one of the ablest jurists of the age. He has always been an advocate of the utmost publicity in the administration of justice, an unflinching opponent of the secret mode of judicial proceedings which prevailed in Germany until 1848, and of the unlimited, absolute, and tyrannical power of the so called *Inquisitions-Prozess*. He is one of the staunchest defenders of the trial by jury in Germany, and was one of the first and few jurists who took deep interest in the science of punishment, not limiting his interest to the criminal trial or penal code. His reformatory activity embraced chiefly the common, civil, and criminal

law of his native country, and the theory of trials as well as punishment. With Thieband and other jurists, Mittermaier defended (theoretically) the codification of the French civil law against the attacks of Hugo, Savigny, and other scholars of the Roman law. His *Lehrbuch des Deutschen Privatrechts* (1821) was subsequently merged in his *Grundriss des gemeinen Deutschen Privatrechts* (3 vols., Ratisbon, 1837-'8). The laws on commercial matters, on bills of exchange, and on maritime affairs are fully expounded in the later editions of this work, which is regarded as a standard authority. His first work on criminal law, *Handbuch des peinlichen Prozesses* (2 vols., Heidelberg, 1810-'12), was afterward republished in an enlarged and modified form under the title of *Das Deutsche Strafverfahren in der Fortbildung durch Gerichtgebrauch und Particulargenossenschaft* (2 vols., 1832), and has passed through many editions. The principles upon which the examination of witnesses in criminal law should be based are discussed in his *Theorie des Beweises im peinlichen Prozesse* (2 vols., Darmstadt, 1821) in *Die Lehre vom Beweise im Deutschen Straf-Prozesse* (Darmstadt, 1834; French translation, Paris, 1848; Spanish, Madrid, 1851), and in his *Anleitung zur Vertheidigungskunst im Criminalprozesse* (translated into Italian by Garba, Milan and Verona, 1858), which is a work of great importance for practitioners at the German bars. He has prepared a complete manual of criminal law (*Lehrbuch des Criminalprozesses*) upon the basis of Feuerbach's great work, which has reached upward of 12 editions. Several of his works treat of the progress in the administration of criminal law, as *Ueber den neuen Zustand der Criminalgesetzgebung* (Heidelberg, 1825); *Ueber die Grundfehler der Behandlung des Criminalrechts in Lehr- und Strafgesetzbüchern* (Bonn, 1819); *Die Strafgesetzgebung in ihrer Fortbildung geprüft* (Heidelberg, 1841-'8); and various changes in the administration of the law are further recorded in the periodicals published under his direction. His most comprehensive work on the theory of trials or on the principles upon which they should be conducted, is entitled *Der gemeine Deutsche bürgerliche Prozess, in Vergleichung mit dem Preussischen und Französischen Civilverfahren und mit den neuesten Fortschritten der Criminalgesetzgebung* (1820-'26). His work, *Die Mündlichkeit, das Anklageprincip, die Öffentlichkeit und das Geschworenengericht* (Stuttgart, 1845), brings the learned investigation and the legislative enactments on all the various branches of the subject of public trial by jury down to the period of its publication; and his *Das Englische, Schottische und Nordamerikanische Strafverfahren* (Erlangen, 1851), treats of the administration of justice in England, Scotland, and the United States. His work on prison reform published in 1858 was followed in 1860 by *Der gegenwärtige Zustand der Gefängnisse in England, Frankreich, Preussen, etc.*—In politics Mittermaier is in favor of liberal institutions, but he cannot be classed

among the more radical German statesmen. He was a member of the Baden legislature for nearly 20 years previous to 1841, when his grief at the death of his son caused him to withdraw from that body. During that time he had officiated three times as its president; and having resumed his seat there in 1846, he was again invested with that dignity during the session of 1847-'8. In 1848 he was first called upon to preside over the provisional parliament (*Vor-Parlament*) at Frankfort; and being afterward chosen to the German parliament as a representative of Baden, he took an active part in the preliminary labors in regard to a new constitution for Germany, and advocated the establishment of a confederacy of German states, but opposed all arbitrary and illegal proceedings. In April, 1849, he returned to Heidelberg; and although he occasionally visited Frankfort during the short remainder of the existence of the German parliament, he has since devoted himself exclusively to his academical duties and to his writings on jurisprudence. Although his hopes for the political regeneration of Germany were baffled by the reactionary spirit which has since prevailed, his legislative activity has at least enabled him to carry out many of the judicial reforms which he had advocated in his writings; and his readiness as a speaker, as well as his sympathy with liberal measures, has given him somewhat the reputation of a German Brougham. He has repeatedly visited Italy, and embodied the result of his observations in a work entitled *Italienische Zustände* (Heidelberg, 1844). He has prepared a German translation, with annotations, of Dr. Lieber's "Letter on Anglican and Gallican Liberty;" and superintended his son's translation of the same author's work on "Civil Liberty" (1860). Like Humboldt, Mittermaier has always placed a noble confidence in the spirit of the rising generation, and repeatedly told his disciples in his lectures, that his whole happiness consists in thinking that most of his youthful hearers will surpass him, their professor, in learning and conscientiousness, and in assisting humanity in its progress toward truth and justice. No European writer is so familiar with American legislation or takes so deep an interest in it. He has also repeatedly visited England and Scotland to study the laws and trials of those countries. His many works and countless essays show that he has his eyes on the legislation of every civilized country, of Portugal and Spain as well as of Sweden and Norway, and every truly liberal or humane movement has through his long life found a ready response in his heart. In 1859 he celebrated his jubilee as public teacher, when he received the most distinguished acknowledgments from almost all parts of Europe.

MITTIMUS, in law, the name of the precept which is addressed by competent judicial authority to a sheriff, constable, or other officer, and to a gaoler or keeper of a prison, commanding them respectively to take and deliver, or to receive into custody and safely keep, a person

charged with the offence named therein, until he is delivered by due course of law. This last clause must not, however, be inserted when the commitment is in the nature of punishment, in which case the time of imprisonment must be stated in its stead; and in the case of a commitment for a bailable offence, the direction is to keep the prisoner in custody "for want of sureties or until he shall be discharged by due course of law." A magistrate may by this precept order a party into custody, when upon examination he is satisfied that the accused is guilty of the offence charged against him, or even when he has good reasons to suspect that he committed it. Though the mittimus need not be drawn with the utmost technical nicety, yet it must be framed with reasonable certainty. It must, at all events, show on its face a charge of a criminal nature. It generally runs in the name of the justice who awards it, though sometimes it is framed in the name of the people. It usually bears the hand and seal of the magistrate who issues it, and discloses the time and place of making it. The prisoner should be described by his name, if that be known; but if he refuse to give it, that fact must be set forth together with a general description of his person. It is not necessary to recite in the warrant either the evidence or the grounds upon which the accused is committed, though it is proper to state that the commitment was made upon a sworn complaint. In New York and Massachusetts, and probably in other states, it is the usual practice to recite in the mittimus the complaint upon which it is founded. It is essential to the validity of the mittimus, that it contain the allegation of a criminal offence; without it, the accused might claim his discharge upon *habeas corpus*. It is important, too, that the particular offence be averred with reasonable certainty. In England it has been held, in a case of imprisonment upon conviction, that where the mittimus alleged a different offence from that upon which the party was found guilty, the magistrate who issued it was liable to an action for a false imprisonment. If an offence be created by statute, the particular language which describes it must be repeated in the mittimus; and as matter of essential form, the description must include the usual words, "contrary to the form of the statute in such cases made and provided." Yet the law will not permit justice to be defeated by a requirement of undue niceness. This was the disposition of the court in New York when it decided that, though upon a defective commitment it must in strictness discharge the prisoner, yet it would do so only *pro forma*, and remand him upon a special order of the court, if there appeared to be probable cause for his detention; and in some states, as in Illinois and Georgia, statutes have expressly provided that no one shall be released for a defect of legal precision or a want of technical form, provided enough appear on the face of the warrant to ascertain the crime for which the party was

imprisoned. So, by statutes, various requirements are made of the magistrate who issues the precept; as, for example, that he write upon it the names and residences of the witnesses in the case, or the amount of bail required.—The gaoler is bound to receive the prisoner, and may be indicted if he refuse to do so. But if he do refuse, the officer to whose custody the accused is committed may himself keep him, until the gaoler consents or is compelled to perform the duty of his office. A constable should take a copy of the warrant and also a receipt for his prisoner from the gaoler. The mittimus is to be handed over to the latter; it is his authority for detaining the accused.

MITYLENE, MYTILENE, METELIN, or MIDULLU (anc. *Lesbos*), an island of the Grecian archipelago, belonging to Turkey, about 7 m. from the coast of Asia Minor, lying chiefly between lat. 39° and $39^{\circ} 20'$ N. and long. $25^{\circ} 50'$ and $26^{\circ} 40'$ E.; length about 45 m., greatest breadth 30 m.; area, 276 sq. m.; pop. 40,000, mostly Turks. On the S. it is indented by two deep bays called Ports Culoni and Lero, the former of which extends to the centre of the island. Both have very narrow mouths, and expand as they stretch inland. The surface is diversified by wooded hills and beautiful plains; the soil is fruitful, and the climate is salubrious. The principal products are olives, wine, fruit, silk, cotton, and pitch; but the imperfect means of irrigation are a great impediment to agriculture. Castro, or Mitylene (anc. *Mytilene*), on the E. coast, Culoni, and Molivo are the chief towns.—The ancient Lesbos was one of the islands of the *Æolians*, and at a very early period contained several rich and populous cities, of which Mytilene and Methymna were the most renowned. The Lesbians joined the revolt of the Ionians under Aristagoras, about 500 B. C., and were in consequence hunted down by the Persians; and in the Peloponnesian war they took the side of Lacedæmon, in punishment for which their lands were divided among a number of Athenian citizens. In the 1st century B. C. the island was under the dominion of Mithridates, and after his defeat was annexed to the possessions of Rome. It was the birthplace of the poets Terpander, Arion, Alcæus, and Sappho (being thus the home of the *Æolian* school of lyric poetry), of the philosophers Pittacus, Cratippus, and Theophrastus, and the historians Hellanicus and Theophrastus. In the modern Greek struggle for independence it suffered greatly, and lost nearly half its inhabitants.

MNEMONICS (Gr. *μνήμη*, memory), the art of rendering artificial aid to the memory. According to Cicero, the first person who suggested a system for this purpose was the poet Simonides of Cos (about 500 B. C.), who was called from a banquet just before the roof of the house fell in and crushed all the rest of the company. On returning he found the bodies so mutilated that no individual could be recognized; but by remembering the places which they had severally occupied at table he was able to distin-

guish them. He was thus led to remark that the order of places may by association suggest the order of things. Cicero and Quintilian both advocated and developed this plan of topical memory, of associating thoughts and words with particular places, images, or signs which might be recalled at pleasure. One of the earliest modern works on the subject is the *Fanis* (1491) of Petrus Ravennas, professor of canon law in Padua. One of his artifices, in the arrangement of symbolical places and images, was to make the most beautiful maidens the letters of a mnemonic alphabet, which according to his experience had a powerful effect in exciting the memory. He would repeat verbatim all the sermons that had been preached during a whole season of Lent, would remember every cast and move in games of dice and chess that were played at the same time, and under the head of 19 letters of his alphabet he preserved ready for quotation 20,000 passages of civil and canon law, 7,000 of Scripture, 1,000 of Ovid, and many others from various authors. John Rombergh de Krypte, in his *Congestorium Artificiosæ Memoriae* (1588), recommended the division of the walls of a series of rooms into separate spaces, each of which was to be marked with numerical, literal, and symbolical alphabets. Thus in learning grammar, a naked man was to personate the singular number, and each of the cases was to be placed on a particular part of his body. A clothed man personated the plural, with a similar disposition of the cases. The distinct rooms were to be devoted, like the shelves of a library, to distinct classes of subjects, and the nomenclature having once been mastered, the suggestions of local relation would enable a man to repeat hundreds of words or ideas that had no real connection with each other. The same method is developed further in the "Castel of Memorie" of Gulielmus Gratarolus of Bergamo, published in English in 1562. The *Ars Memoriae* of Marafortius (1562) grouped all necessary reminiscences around 44 images contained in the palms of the two hands. Baptista Porta, in his *Ars Reminiscendi* (1576), seems to have first employed the mode of writing now common in rebuses. About 1609 Lambert Schenkel astonished all classes in France, Germany, and the Netherlands by his mnemonic performances. Twenty-five Latin sentences were dictated to him and numbered, and after twice reading them aloud he was able to repeat them backward as well as forward, to give the number of each, or to give the sentence of any number that was required. Some of his pupils would answer in the same way concerning 200 sentences. The system was obscurely explained in his *Gasophylacium Artis Memoriae* (1610). More elaborate than any preceding scheme was the repository for ideas suggested by John Wallis in his *Mnemonice* (1618). This repository was to be a series of imaginary throne-shaped edifices, with their interior walls variously divided and colored. Every person was to have this repository constantly present before

his mind, within which all his ideas were to be arranged according to their qualities, quantities, positions, and colors. The management of such a mnemonic vehicle would seem to be as severe a task as the direct remembrance of all its contents. The plan only became more complicated as improved by Henry Herdson (1651). The *Memoria Technica* of Grey (1780) contains a system which many persons have found of use in the study of history and science in remembering dates and numbers. The letters are substituted for figures and combined into words, the vowels however being of no value, and serving only to connect the consonants. Harmonious words may thus be formed, which are more easily remembered than the numbers which they represent. The most complicated system of mnemonics is that of Feinagle, who began to lecture in Paris in 1807 and in England in 1811. He divides the walls, ceiling, and floor of a room into 50 imaginary equal compartments. To each compartment is assigned a particular hieroglyphic, with which it is indelibly associated. These elements having been thoroughly mastered, some association, no matter how ridiculous, is formed between the object to be remembered and one of the hieroglyphs. The substitution of letters for figures also belongs to his system, and the memory of events, characters, and dates is combined. Thus a willow tree on the hieroglyph of the tower of Babel, with a piece of dead laurel hanging from it, suggests William the Conqueror. Willow stands for William; the tower of Babel, being the first hieroglyph, makes it William I.; the laurel gives the epithet of the conqueror; and the consonants in "dead" represent 66, which, with the 1,000 understood through the series, gives 1066, the date of the conquest. A simpler system was taught in the United States by F. Gouraud, who published an "Art of Memory," and "Mnemonic Dictionary" (New York, 1845). Among the more recent professors of mnemonics, Gen. Bem and the Dane, Reventlow, now a resident of the United States, deserve mention.

MNEMOSYNE (Gr.), in classical mythology, the goddess of memory, one of the Titanides, daughter of Uranus, who became by Jupiter the mother of the Muses.

MOAB, an ancient people of Syria, who lived in the region E. of the Dead sea and the Jordan, between the Ammonites and the Edomites. They are derived in Scripture from Moab, a son of Lot. They were a pastoral people, the valleys and slopes of their mountainous regions being well adapted for grazing. They also produced wine and corn. The capital was Ar or Rabbath-Moab, S. of the Arnon. Before the exodus of the Hebrews from Egypt, the Moabites had conquered their possessions from a gigantic tribe called Emim, but subsequently lost the portion of them between the Jabbok on the N. and the Arnon on the S. to the Amorites, from whom it was conquered by Moses and divided between the tribes of Gad and Reuben. The king of Moab vainly sought help from Balaam

against the Hebrews, but suffered no attack on his possessions. The hostility between the two new neighbors, however, was almost continual, and mutual oppression was frequently exercised. In a general insurrection, Ehud, having assassinated the Moabite king, shook off the yoke which had long pressed upon his people. A time of peace followed. Saul waged war against Moab, and David finally made them tributary. After the division of the Hebrew state, they revolted against Ahab, king of Israel, whose son Jehoram tried in vain to reconquer their territory. They subsequently made various incursions into the Hebrew possessions, and appear in later times to have reoccupied the land between the Jabbok and Arnon, probably after the exile of the 10 tribes, and they also assisted the Babylonians in their invasion of Palestine. But they, too, were subdued by the conquerors. Like those of Ammon and Edom, their name was finally lost under that of the Arabians. Their licentious and bloody idolatry of Baal-Peor and Chemosh made them an object of national detestation to the Hebrews, no less than their frequent hostilities, and they are often contemptuously spoken of in the prophets.

MOBILE, a S. W. co. of Ala., bounded E. by Mobile river and bay, S. by the gulf of Mexico, and W. by Mississippi; area, nearly 1,400 sq. m.; pop. in 1855, 29,775, of whom 8,857 were slaves, and 1,041 free persons of color, the latter consisting mainly of colored creoles, the citizens and their descendants of the Spanish colony at the time of its cession in 1818, still exercising certain privileges of citizenship secured to them by treaty. The surface is generally uneven, except in that portion bordering on the bay and gulf, and the soil is sandy and poor, mainly covered with forests of pine. It has many streams of pure water, and, except on the low borders of the river, is very healthful. The productions in 1850 were 84,500 bushels of Indian corn, 44,720 of potatoes, and 90,402 lbs. of rice. There were 12 saw mills, 2 grist mills, 2 iron foundries, 19 churches, and 1,774 pupils attending public schools. The city of Mobile, the capital, is in the E. part of the county, about midway between its N. and S. limits. In the N. E. portion, on the river Mobile, is the site of Fort Stoddard, an important military post previous to 1818, when the country S. of lat. 31° N. was in possession of Spain. It was here that the customs of the United States were collected during that period. It is memorable also as the place to which Aaron Burr was taken for safe keeping in 1807, after his arrest, which occurred in the vicinity. Near the site of Fort Stoddard is the Mount Vernon arsenal of the United States, on an elevated, secluded, and picturesque spot, about 2 m. from the river. In the N. W. part of the county, 83 m. from Mobile, and on the Mobile and Ohio railroad, is the village of Citronelle. Spring Hill, the seat of a Roman Catholic college, is about 6 m. W. from Mobile. A few miles S. of the mainland, in the

gulf of Mexico, immediately W. of the entrance of Mobile bay, and forming a part of the county, is Dauphine island, memorable as the seat of one of the first French settlements, established there by Bienville in 1702. It was originally called Massacre island, from the number of human bones found upon it, and still bore this name until a very recent period in the colloquial usage of the creole inhabitants. For a number of years it was at intervals the seat of government of the colony of Louisiana; and it has been more than once the scene of contest in the various wars in which France, Spain, Great Britain, and the United States have been involved, beside having been once or twice plundered by buccaneers. At present it is only inhabited by a few poor families, beside the persons employed in the construction of Fort Gaines, a work in process of erection on the E. extremity of the island, for the defence of the entrance to Mobile bay. Petit Bois island, which lies further W., was originally a part of Dauphine island, but was separated from it by a great hurricane about the year 1777. It is now entirely uninhabited.—That portion of the county S. of lat. 31°, together with the corresponding portion of what is now Baldwin co., being originally part of the French colony of Louisiana, was ceded to Great Britain in 1763. In 1783 it passed into the possession of Spain, simultaneously with the retrocession of Florida to that power by Great Britain. It continued in the possession of Spain until 1818, when it was seized by the United States, which had claimed it for 10 years previous, as a part of the Louisiana purchase. The right of Spain, however, was not formally relinquished until the treaty of 1819. Mobile co. (including the city) has a special public school system of its own, which has been in operation, with considerable success, since 1852.

MOBILE, the principal city and only seaport of Alabama, situated on the W. side of Mobile river, immediately above its entrance into the bay of the same name, in lat. 30° 41' 26" N., long. 88° 1' 29" W.; pop. in 1850, 20,515; in 1860, about 30,000. The corporate limits extend 6 m. N. and S., and 2 or 3 m. W. from the river. The thickly inhabited part of the city, however, extends for about a mile along the river, and nearly the same distance back to the westward. The site of the city is a sandy plain, gradually rising as it recedes from the water. The streets are generally regular, well paved, and shaded. There are several fine public buildings, among which is a handsome market house with rooms for the municipal officers in the upper story. The custom house has also accommodations for the post office and U. S. courts. Among the other noticeable buildings are the theatre, Odd Fellows' and temperance halls, guard house and tower, and the Barton academy, occupied by the public schools. There are 2 banks, a savings bank, 28 churches (8 Baptist, 1 Bethel, 4 Episcopal, 8 Methodist, 4 Presbyterian, and 3 Roman Catholic, including

a fine cathedral now [1860] nearly completed, a Jewish synagogue, 8 orphan asylums, an infirmary conducted by the sisters of charity, a city and a marine hospital, several other benevolent institutions, and a literary society with a good library. A medical college was founded in 1859, and has a spacious edifice in course of erection. The suburban villages of Turner-ville, Toulminville, Jacksonville, Summerville, Spring Hill, Cottage Hill, &c., near the city, are well supplied with churches and schools. St. Joseph's college at Spring Hill, and the academy of the Visitation (for girls) in Summerville, are flourishing institutions under Roman Catholic control. There are many handsome villas and cottages in the suburbs and environs. Mobile is lighted with gas, and supplied with water of unusual purity and excellence, which is brought a little more than 5 m. from the foot of Spring hill. The construction of the Mobile and Ohio railroad, which is to connect Mobile with Cairo, at the mouth of the Ohio river, and is now (1860) approaching completion, promises to give fresh impetus to its trade. The Mobile and great northern road, also in active progress, will connect it with Montgomery and the roads leading thence to all parts of the eastern states. Several city and neighborhood railroads are about to be constructed. Among the industrial establishments are 2 iron foundries, a rosin oil factory, several ship yards, a dry dock, and a great number of cotton presses. The exports of cotton from the port of Mobile for a period of 5 years, each ending Aug. 31, have been as follows: 1855-'6, 680,657; 1856-'7, 495,860; 1857-'8, 515,371; 1858-'9, 681,094; 1859-'60, 789,057; average of the 5 years, 682,808 bales. The other exports consist of lumber, turpentine, rosin oil, &c., and are small in comparison with the amount and value of the cotton. The whole value of exports and imports for 5 years, ending Dec. 31, was as follows:

Years.	Exports.	Imports.
1855.....	\$16,612,006	\$4,115,000
1856.....	19,917,384	4,415,000
1857.....	21,452,498	4,415,000
1858.....	23,553,736	6,415,000
1859.....	30,079,711	7,415,000
Average.....	\$23,419,266	\$5,415,000

The trade of Mobile is much hindered by want of a sufficient depth of water in its harbor. Vessels drawing more than 8 or 10 feet are obliged to anchor in the bay, at a distance of some 25 m. or more from the city, and receive their cargoes by the aid of steamers that ply between the city and the anchorage. By a recent act of the Alabama legislature a board of commissioners has been created, with authority to take measures for deepening the harbor.—The climate of Mobile, although debilitating in summer to some constitutions, is generally healthful, except for occasional visitations, at irregular intervals, of epidemic yellow fever. The following are the seasons in which these visitations have occurred, within a quarter

of a century: 1837, 1839, 1843, 1847, 1853, and 1858. The epidemics of 1839 and 1858 were the most fatal. In 1858, between Aug. 1 and Oct. 26, there were 1,256 deaths, of which 1,072 were attributed to yellow fever, being supposed to be equivalent to about one tenth of the population actually resident and remaining within the city during the epidemic. Mobile, however, enjoys the advantage of having high and healthful hills within a few miles N., W., and S. W. of the city, which afford permanent or summer residences.—Mobile was the original seat of French colonization in the South West, and for many years the capital of the colony of Louisiana. In 1702, Lemoine de Bienville, acting under the instructions of his brother Iberville, transferred the principal seat of the colony from Biloxi, where it had been established 8 years previously, to a point on the river Mobile supposed to be about 20 m. above the present site of the city, where he established a fort to which he gave the name of St. Louis de la Mobile. At the same time he built a fort and warehouse on Isle Dauphine, at the entrance of Mobile bay. The settlement at Biloxi was soon afterward broken up. In 1704 there was an arrival of 20 young girls from France, and the next year of 28 others, selected and sent out under the auspices of the bishop of Quebec, as wives for the colonists, beside a considerable accession of soldiers for the garrison. Many of the original settlers were Canadians, like Iberville and Bienville. In 1705 occurred a severe epidemic—supposed to be the first recorded visitation of yellow fever—by which 85 persons were carried off. The year 1706 is noted for the “petticoat insurrection,” which was a threatened rebellion of the females in consequence of dissatisfaction with the diet of Indian corn to which they were reduced. The colony, meanwhile, frequently suffered from famine, as well as from the attacks of Indians, although relieved by occasional supplies sent from the mother country. In 1711 the settlement was nearly destroyed by a hurricane and flood, in consequence of which it was removed to its present situation. In 1712 the king of France made a grant of the whole colony to Antoine Crozat, a wealthy French merchant, and in the following year Bienville was superseded as governor by M. de la Motte Cadillac. In 1717 Crozat relinquished his grant to the French government, and Bienville was reinstated. In 1723 the seat of the colonial government was transferred to New Orleans. In 1763, by the treaty of Paris, Mobile, with all that portion of Louisiana lying E. of the Mississippi and N. of Bayou Iberville, Lakes Maurepas and Pontchartrain, passed into the possession of Great Britain. In 1780 the fort—the name of which had been changed to Fort Condé, and subsequently by the British to Fort Charlotte—was captured by the Spanish general Don Galvez, and in 1783 its occupancy was confirmed to Spain by the cession to that power of all the British possessions on the gulf of Mexico. On April 13, 1813, the

Spanish commandant, Cayetano Perez, surrendered the fort and town to Gen. Wilkinson, since which time it has continued in possession of the United States. At that period the population, which in 1785 had amounted to 746, was estimated at only 500 (exclusive of the garrison), half of whom were blacks. In Dec. 1819, Mobile was incorporated as a city.

MOBILE, the name of a river and bay in the southern part of Alabama, derived from that of a tribe of Indians (the Mauvilians, or Mobilians) who inhabited the adjacent country at the time of its first settlement by Europeans. The river Mobile is formed by the confluence of the Alabama and Tombigbee. A few miles below this point it divides into two branches, the eastern one of which takes the name of Tensas, the western retaining that of Mobile. Before reuniting, both these streams separate into several other subdivisions, all of which meet in one common embouchure, at the head of Mobile bay. The length of the Mobile river is about 50 m., and its general direction is south. In the lower part of its course the banks are marshy and alluvial.—The bay of Mobile is about 80 m. in length from N. to S., with a general width of 10 or 12 m., except where it expands, on the S. E., into the subsidiary bay of Bon Secours, which extends some 8 or 10 m. further to the eastward. The entrance from the gulf of Mexico, between Mobile point on the E. and Dauphine island on the W., is about 8 m. wide, and is commanded by Fort Morgan on Mobile point, and Fort Gaines (yet unfinished) on Dauphine island. The bay has another outlet on the S. W. through Grant's pass, N. of Dauphine island, which communicates with Mississippi sound. Through this channel steamers and other vessels of light draught generally pass when plying between Mobile and New Orleans. The bar in front of the main entrance of the bay admits of the passage of vessels drawing 21 or 22 feet. The ordinary anchorage for ships is 4 or 5 m. within the entrance of the bay. The whole of the upper portion of the bay is shallow, and is supposed to be gradually filling up with sedimentary deposits from the rivers that flow into it. Measures are now (1860) in progress, however, for the opening of a channel for ships to the city of Mobile. There is a revolving light on Mobile point; a fixed light on Sand island, 8 m. S., and immediately in front of the entrance, and another on Choctaw point, at the head of the bay, a little below the city of Mobile.

MOBILE POINT, the apex of a long, low, narrow, sandy peninsula between the gulf of Mexico on the south, and Bon Secours bay and Navy cove on the north. The point is the eastern limit of the entrance into Mobile bay. It is the site of Fort Morgan, a work constructed at an expense of about \$1,250,000. Fort Morgan is built on the site of Fort Bowyer, famous for the repulse of an attack by the British, Sept. 14, 1814. The fort, which was very imperfectly constructed, was commanded by Major Lawrence, with a garrison of only 130, includ-

ing men and officers, and 20 pieces of artillery. It was attacked by a squadron of 2 sloops of war and 2 brigs, assisted by 600 Indians on land, with whom were associated 180 marines from the ships. The attack continued for 8 hours, when the enemy were repulsed, with the loss of the *Hermes*, Commodore Percy's flag ship, which ran aground and was burned, and 282 men killed and wounded. Eight of the garrison were killed. After the battle of New Orleans, Fort Bowyer was again invested by the whole British force, to which Lawrence surrendered, Feb. 12, 1815.

MOBILIER, CRÉDIT. See CREDIT MOBILIER.

MOOANNA, or MOKANNA. See ATHA BEN HAKIM.

MOCHA, or MOKHA, the principal seaport town of Arabia, in the province of Yemen, on the Red sea, 40 m. N. N. W. from the straits of Bab-el-Mandeb; lat. $13^{\circ} 20' N.$, long. $48^{\circ} 20' E.$; pop. about 7,000. It extends N. and S. along the shore for about $1\frac{1}{2}$ m. The houses are generally built of stone, are lofty, adorned with stucco ornaments, and brilliantly white. The chief public edifices are the mosques, one of which is of great magnitude. Mocha is the principal port and emporium of the dominions of the imam of Sana, and owes its importance to the coffee for which it is celebrated, and which is brought thither from the interior. Although the export of Mocha coffee has much declined, it is still said to average about 10,000 tons yearly. The bay is formed by two promontories, at the extremity of each of which a fort has been erected for the protection of commerce, but vessels drawing over 10 or 12 feet of water must anchor outside.

MOCHUANA. See BECHUANA.

MOCKING BIRD, an American passerine bird, of the sub-family *miminae*, and genus *mimus* (Boie). The sub-family includes the cat-bird, brown thrush, and nearly 20 other mockers, arranged by Gray under the single genus *mimus*, but subdivided by Cabanis and others into nearly as many genera as species. The restricted genus *mimus* has the bill shorter than the head, slightly curved from the base, and notched at the tip; the gape furnished with bristles; lower jaw with no longitudinal ridges; wings moderate and rounded, with the 1st quill very short, the 2d longer, and from the 8d to the 7th nearly equal and longest; tail long and graduated; tarsi longer than the middle toe, robust, and covered in front with broad scales; toes long, with sharp curved claws. The size is large, and the general appearance thrush-like. The species of this genus are found in North and South America, the West India, and the Galapagos islands; they are shy, active, and migratory, feeding on insects, berries, and worms; the song is highly pleasing, and the powers of imitation very great. The common mocking bird (*M. polyglottus*, Boie) is about $9\frac{1}{4}$ inches long, with an extent of wings of $13\frac{1}{4}$; the bill and legs are black; the general color above is ashy brown, a little the darkest in the

centre; the under parts white, with a brownish tinge except on the chin, and a shade of ash across the breast; a pale superciliary stripe; wings and tail nearly black; lesser wing coverts like the back, the middle and greater tipped with white, forming 2 bands; outertail feather white, the 2d mostly so, the 8d with a white spot on the end, and the rest, except the middle, slightly tipped with white. It is found in the southern United States, from the Atlantic to the high central plains, replaced by the *M. rufus* (Bonap.) to the westward. The song of the mocking bird is regarded as superior to that of the nightingale by those who have heard both; in its mellowness, modulations and gradations, extent of compass, and brilliancy of execution, it is unrivalled. Audubon considers it absurd to compare the best notes of the nightingale "to the finished talent of the mocking bird." Its powers of imitation are such that to a blind man it would seem that the whole feathered tribe had assembled to try their skill in song, when it chooses to exercise the faculty; it can adapt its tongue to any note from the feeble chirp of the chicken to the scream of a hawk; it deceives the sportsman, cheats and terrifies birds, whistles to the dog, and imitates almost every sound, animate or inanimate. Like the nightingale, it sings charmingly at night, commencing as soon as the moon rises. In captivity its habits are very amusing from its imitating various household noises. Its finest song is during the breeding season. It delights to build a nest in gardens near houses; the eggs are usually 5, light green with brown spots and blotches; they begin to pair toward the end of March, and 8 broods are generally raised between that and the last of September. They remain in the gulf states all the year; some go to the north in the spring, returning in October; they are most plentiful near the shore, in sandy districts scantily furnished with trees. From the low position of the nest, snakes and cats often climb the trees and devour the eggs and young; but they are generally protected by man, for their sociable habits and pleasing song; in winter they live principally about the farm houses and plantations. Their motions on the ground are light and elegant, accompanied by frequent openings of the wings and tail; the flight is short and jerking. The call note is very mournful, like that of the *M. rufus* (Boie), the French mocking bird so called, which Audubon terms its first cousin. Its courage is great, sufficient to defend it against the birds of prey. It is easily reared by hand from the nest, and becomes very familiar and affectionate in confinement; its vocal powers, though great in captivity, are very much greater in its native haunts; it is long-lived, and a fine singer always commands a high price. The female differs little from the male, but the plumage is somewhat duller. The *M. carolinensis* (Gray) has been described under *CAROLINENSIS*, and is a skilful mocker. Other species are described in South America, and on the Pacific coast.

North America, all possessing remarkable powers of song.

MODENA, a state of N. Italy, bounded N. by Mantua, E. by Ferrara and Bologna, S. by the Mediterranean, and W. by Genoa and Parma; area, about 2,800 sq. m.; pop. in 1858, 604,512, all Roman Catholics excepting about 200 Protestants and nearly 8,000 Jews. It comprises 6 divisions, viz.: Modena proper, pop. 212,818; Reggio, 167,547; Guastalla, 76,815; Frignano, 38,418; Garfagnana, 50,672; Massa Carrara and Lunigiana, 58,757. The last 2 divisions lie S. of the Apennines, the main ridge of which crosses the southern portion of the state, sending off spurs over a large extent of country. The highest summits are Monte Cimone and Campoazghena, estimated respectively at 7,000 and 6,500 feet. The territory of Modena extends from the Po to the Mediterranean, but the portion of sea coast is small and destitute of harbors. About $\frac{1}{4}$ of it forms part of the great and fertile plain of Lombardy, watered by the Panaro, which rises at the foot of Monte Cimone and falls into the Po in the territory of Ferrara. The principal river is the Secchia, which after a winding course of 100 m. joins the Po in Mantua. The principal productions are wheat, maize, hemp, flax, rice, pulse, olives, wine, and silk. Agriculture is in a backward condition. The farms are small, few exceeding 60 acres; dairy pasture prevails to some extent in the valley of Garfagnana; a few families own the large flocks of Apennine sheep; and the masses of the people, especially in the mountain districts S. of the Apennines, can seldom afford to eat meat. The vine is extensively cultivated in the neighborhood of Reggio and of the city of Modena. The mountains abound with oak, pine, and chestnut trees. Iron and other minerals are found, and the marble of Carrara is a lucrative article of export. The manufactures of silks, linen, canvas, leather, &c., are on a very small scale, and the commerce is equally trifling. The most active city of Modena is Reggio, the birthplace of Ariosto.—MODENA (anc. *Mutina*), the capital of the above state, is situated in a beautiful plain between the Panaro and the Secchia, about 25 m. W. N. W. from Bologna; pop. in 1855, 81,052. It has a citadel, is surrounded with ramparts, and is divided into the new and old city, a part of the *Æmilian* way intersecting the whole city. The cathedral, a Gothic edifice begun at the end of the 12th century, contains interesting tombs of the Rangoni family, one of which was designed by Giulio Romano, and is celebrated on account of its square marble tower, one of the highest in Italy, still containing the wooden bucket, *la secchia rapita*, once the cause of a feud between the Geminiani or Modenese and Petronii or Bolognese (so called from their respective patron saints), and immortalized in Tassoni's poem of that name. There are a great number of other churches in Modena; the most noticeable of them, on account of their colossal marbles, are those of St. Vincenzo, St. Agostino,

and San Francesco. The former ducal palace in the great square is a superb edifice, and contains a large collection of paintings by Guido, the Carracci, Andrea del Sarto, Carlo Dolce, Guercino, Pomaranzio's "Crucifixion," and other remarkable works; but the best, including the celebrated *Notte* by Correggio (of which a copy is in the palace), were purchased by the elector of Saxony and are now in Dresden, while others were taken by the French. It still remains, however, one of the best collections in Italy. In one of the rooms is a recumbent Cleopatra by Canova, and the ceiling of the gallery is painted in fresco by Francesconi. The palace library, known as the *biblioteca Estense*, has about 60,000 volumes, and is particularly rich in MSS. A few Roman antiquities are pointed out at Modena, and the hymn sung by the Roman sentinels while they stood watch against the enemy on the summit of the city wall, is said to be still preserved.—The ancient Mutina is supposed to have been of Etruscan origin. According to Livy, the territory in which it was situated had been taken from the Boians, and after the final defeat of the latter it was colonized by the Romans (183 B. C.). According to Plutarch, Mutina, defended by Marcus Brutus, the father of Cæsar's murderer, was almost the only place able to offer any resistance to the arms of Pompey (78), and it became still more celebrated by the siege which it sustained and the battles fought between Decimus Brutus and Mark Antony, known as the Mutinian war (48). Cicero and other writers are unanimous in extolling the prosperity and strong military position of the city at that time; but afterward it suffered much from the calamities which befell the other parts of the empire, and toward the end of the 4th century it is described by St. Ambrose as in a deplorable condition. It survived, however, this crisis, and also the still more terrible ravages of Attila in the middle of the 5th century. Under the Lombard kings Mutina became the frontier city of their dominions toward the exarchate. At the close of the 6th century it was taken by the Greek emperor Mauricius. Subsequently it was restored to the Lombard kingdom of Italy, but according to Muratori it was in a decaying condition for several centuries, chiefly owing to inundations, which reduced almost the whole of the city to the condition of a morass. Many of the remains of antiquity perished in the swamps, others were employed in the construction of new edifices, and some are now occasionally brought to light by excavations. After having been governed by Frankish counts for some time after the 9th century, it passed in the 11th under the government of its bishops. In the following century the city belonged to the countess Matilda of Tuscany. Subsequently it formed for some time part of the Lombard league; and after suffering from the family feuds which distracted for a long period the cities of N. Italy, it passed along with Ferrara into the possession of the Torelli, and submitted at the end of the 13th century

to the princes of the house of Este, who became the rulers of the city and its territory. The title of duke of Modena was formally conferred upon Borso of Este in 1452 by the emperor of Germany, and that of Reggio and Ferrara by Pope Paul II. Cesare of Este was compelled to evacuate Ferrara, Jan. 28, 1598, the city having been seized by Clement VIII. as a papal fief; but he retained the duchies of Modena and Reggio. In 1797 they were taken by Napoleon from the duke Ercole Rinaldo, and annexed to the Cisalpine republic. His only child and daughter Maria Beatrice (1752-1829), the last offspring of the Italian branch of the house of Este, married the archduke Ferdinand, 8d son of Francis I. of Austria, who became the founder of the Austrian house of Este. Her oldest son Francis IV. (1779-1846), who inherited the possessions of Massa Carrara, was reinstated as duke of Modena in 1814, and was succeeded in 1846 by his son Francis V. (born June 1, 1819), who married in 1842 a sister of the present king and a daughter of the ex-king Louis of Bavaria. His eldest sister is the wife of the count de Chambord, and his younger sister of a son of Don Carlos, another pretender. The death of Maria Louisa, the widow of Napoleon I. and duchess of Parma (Dec. 16, 1847), added the duchy of Guastalla to the Modenese possessions. Francis V., as well as his predecessors, was so much opposed to liberal systems of government, that in 1847 and 1848 he was compelled to depend on Austrian troops for protection against his own subjects. The Jesuits were expelled from Modena in March; after the revolt of the Viennese the duke was ready to make concessions, but it was too late, and Bolognese volunteers assisted the people (March 24) in overturning his throne and establishing a provisional government. He was compelled to resort to flight, but the triumph of Austria over Sardinia emboldened him to return to Modena (Aug. 10), although he was unable to make his rule acceptable to the people. An attempt upon his life was made Nov. 18, 1848; and after the resumption of hostilities between Austria and Sardinia he again deserted the city (March 14, 1849), which he left under the charge of his ministers, a garrison of Austrian and Modenese soldiers occupying the citadel. He came back to Modena in May, and endeavored to popularize his government by various reforms; but in June, 1850, the Jesuits were reinstated in their property and privileges. After the liberation of Lombardy by the Sardinian and French armies, and the invasion of parts of his territory, he fled from Modena (June 11, 1859), instituting a regency, which was overthrown two days afterward by the people, who declared themselves in favor of annexation to Sardinia, and Modena now forms part of that kingdom.

MOELLER, Jens, a Danish theologian and author, born in Copenhagen in 1779, died there in 1838. He was a graduate of the university of his native city, and officiated there for many

years as professor of theology. The *Theologisk Bibliothek*, and the *Tidskrift for Kirke og Theologia*, are chiefly composed of his contributions, and comprise 44 vols. (Copenhagen, 1811-'34). His essays on the history of Denmark are principally contained in the *Historisk Kalender* (3 vols., 1814-'17), which he prepared in concert with Engelstoft, and in the *Mnemosyne* (4 vols., 1830-'34).

MOERIS, a lake of Egypt very celebrated in antiquity, situated near Crocodilopolis, now Medinet-el-Fayoom. The earliest and fullest account of it is given by Herodotus, who says: "Wonderful as is the labyrinth, the work called the lake of Moeris, which is close by the labyrinth, is yet more astonishing. The measure of its circumference is 8,600 furlongs, which is equal to the entire length of Egypt along the sea coast. The lake stretches in its longest direction from north to south, and in its deepest parts is of the depth of 50 fathoms. It is manifestly an artificial excavation, for nearly in the centre there stand two pyramids, rising to the height of 100 feet above the surface of the water, and extending as far beneath, crowned each of them with a colossal statue sitting upon a throne. The water of the lake does not come out of the ground, which is here excessively dry, but is introduced by a canal from the Nile. The current sets for 6 months into the lake from the river, and for the next 6 months into the river from the lake. While it runs outward it returns a talent of silver daily to the royal treasury from the fish that are taken; but when the current is the other way, the return sinks to one third of that sum. The natives told me that there was a subterranean passage from this lake to the Libyan Syrtis, running westward into the interior by the hills above Memphis." Herodotus ascribes the formation of this lake to a king Moeris who lived about 1850 B. C., and who is supposed by some modern Egyptologists to be identical with Amenoph III., the Memphite of the later Greeks and Romans. The Greek historian confounds together the natural lake Birket-el-Keroun, which is still existing in the province of Fayoom, and the artificial lake Moeris, which was connected with the former by canals. During the annual inundation of the Nile, at which time they were probably united by Herodotus, the two lakes would appear as one. Moeris in reality was an extensive reservoir secured by dams and communicating canals with all parts of Fayoom, to supply which with water was the object of its construction. M. Linant thinks he has found traces of the pyramids in the lake mentioned by Herodotus.

MOESIA (in Greek, Mysia, or Mysia in Europe), an ancient country of eastern Europe, bounded N. by the Savus (Save) and Danube (Danube), which separated it from Pannonia and Dacia; E. by the Euxine; S. by the Haemus (Balkan) and Scardus ranges, separating it from Thrace and Macedonia; and W. by the Illyria (Drin), which partly separated it from Italia. It thus corresponded to the modern

Turkish provinces of Bulgaria and Servia. It was divided by the Romans, who conquered it in the early period of the empire, into Upper and Lower (or western and eastern) Mœsia, separated by the small river Cœbrus. The western division was traversed by the Margus (Morava), and contained the important towns of Singidunum (now Belgrade) and Naissa (Nissa); in the eastern division was Sardica. The original inhabitants of Mœsia were various Thracian tribes, the Triballi, Peucini, and others. Under Aurelian the Dacian colonies were removed there, when the middle part of the province also received the name of Dacia Aureliani. It was occupied by the Goths in the 4th century, who were called from their new abode Mœso-Goths, and became formidable to the eastern empire. Other hordes of barbarians frequently traversed it afterward.

MOGADORE, **MOGADOR**, **MOGODOR**, or **SURRAH**, a fortified seaport town of Morocco, on the Atlantic, 125 m. S. W. from the city of Morocco; lat. $31^{\circ} 50' N.$, long. $9^{\circ} 20' W.$; pop. about 16,000, $\frac{1}{4}$ of whom are Jews. It stands on an eminence, and is surrounded by a low sandy flat, which at high water is overflowed by the sea. It consists of two parts, one called the citadel, inhabited by Moors, and the other by Jews. The town is well supplied with water by an aqueduct. The houses are generally large and flat-roofed. Some of the mosques are splendid specimens of architecture. The trade, which is considerable, is chiefly in the hands of Jews. The chief exports are wool, gum, wax, hides, almonds, honey, ostrich feathers, ivory, and gold dust, and were valued in 1855 at \$1,500,000. The imports amounted in 1855 to \$800,000. The harbor is formed by an island S. of the town, and is considered the best on the W. coast of the empire. Mogadore was founded in 1760 by the emperor Sidi Mohammed, who intended it for his commercial capital. It was bombarded by the French under the prince de Joinville, Aug. 15, 1844. It suffered also in its trade during the recent war with Spain (1859-'60), and considerable amounts of money were collected by the Jews in the United States for the relief of those in Mogadore and other parts of Morocco.

MOGULS, a corruption of the term Mongols, used in Hindostan to designate the Tartars who repeatedly invaded that country in the middle ages, and who finally made themselves masters of Delhi in 1526, and placed their leader Baber, descendant of Tamerlane, on the imperial throne of that city. The successors of Baber are known in history as the Mogul emperors, of whom the most eminent were Akbar (1556-1605), Jehangheer (1605-'27), and Aurungzebe (1658-1707). During these reigns the Mogul empire comprised nearly the whole of Hindostan, and in Europe the emperor was commonly called the Great Mogul. From the time of Aurungzebe the dynasty rapidly declined in power, until in the latter half of the 18th century it possessed only the semblance of sover-

eignty. In 1803 a British resident was stationed at Delhi, and ruled what remained of the empire in the name of the emperor till 1827, when even the appearance of authority was taken away, and the Great Mogul became merely a titled pensioner of England. The last of the dynasty, Mohammed Bahadoor, was deposed and transported in Dec. 1858, for complicity in the sepoy mutiny, and his family stripped of all titles and privileges.

MOHÁCS, a town of S. Hungary, in the county of Baranya, on the W. arm of the Danube, 25 m. E. S. E. from Fünfkirchen; pop. about 11,000. It is a station of the Danube steamers, and a centre of considerable trade. Two great battles were fought in its vicinity, marking the beginning and the end of Turkish sway in Hungary. The first took place Aug. 29, 1526, between Solyman the Magnificent and the Hungarian king Louis II. of the house of Jagiello. The Turks, who were flushed by recent conquests, many times outnumbered the hastily collected Hungarian army of about 25,000 men; but the warlike nobility were so eager to attack the enemy, that it was resolved not to wait the arrival of some reinforcements approaching under John Zápolya. The issue was bloody and disastrous. No fewer than 22,000 Hungarians fell, and among them were 500 magnates. The king perished in the flight, and his body was found in the marshy brook Osellye. His wife, Mary, a sister of Ferdinand of Austria, who in his turn had married Anne, the sister of Louis, hastened to carry the crown of Hungary to her brother, who was soon after enthroned at Presburg by a part of the nobles, while others elected Zápolya at Stuhl-Weissenburg. The contest between the two rival houses was afterward terminated by treaties; that between the Hapsburgs and the Turks was decided by arms, the second battle of Mohács (Aug. 12, 1687) closely following the reconquest of Buda from the Moslems. The Turks were commanded by the grand vizier, the Austro-Hungarian army by Charles of Lorraine; the former suffered a defeat and loss almost equalling that of the Hungarians 161 years before.

MOHAMMED (Arabic, the Praised), or **MAHOMET**, the founder of one of the most widely spread religions of the world, born in Mecca, according to Muir, in 570, but according to others in 567, 569, or 571, died, according to Reinaud, at Medina, June 8, 632. According to his Mohammedan biographers, his birth was accompanied by strange miracles; the sacred fires of the Parsees were extinguished, the palace of the Persian king was shaken by an earthquake, the lake Sawa dried up, and innumerable other prodigies took place. His family (Hashem) belonged to the distinguished tribe of Koreish, and were hereditary guardians of the Caaba; nevertheless his parents were poor. His father Abdallah died two months after his birth, and the whole property which he left to his widow Amena consisted of a house, 5 camels, an Abyssinian female slave, a few sheep,

and a slave called Sakran. The orphan was confided for a little more than two years to the care of a Bedouin nurse, Halima, who returned him to his mother in consequence of spasmodic fits which she attributed to evil spirits. At the age of 6 years he lost his mother, and was brought by a female slave to his grandfather Abd el Mottallib. Two years later he lost also his grandfather, and was then adopted by his uncle Abu Taleb, who held at that time the key of the Caaba. With him young Mohammed (in his 9th or 12th year) made journeys through Syria and other countries, and became acquainted with a Christian (probably Nestorian) monk, called by some Bahira, by others Serdjis, who predicted his future greatness. Another uncle, Zubeir, he accompanied in his 16th year on a mercantile trip to southern Arabia, and, in his 20th year, in a war against the Beni Kinanah. In his 25th year he earned his livelihood as a shepherd near Mecca, and then joined for a short time the business of a linen trader named Saib. At Hajasha, a market 6 days' journey S. of Mecca, Mohammed became acquainted with a nephew of the rich widow Kadijah, who recommended him to his aunt as a trustworthy young man. Mohammed, compelled by poverty, offered to her his services, which were accepted. Several business journeys which he made for Kadijah through Syria and Arabia, not only enlarged his knowledge of the world, but also gained for him the esteem of Kadijah to so high a degree, that she determined to marry him. According to the common tradition Kadijah was then 40, and Mohammed a little over 25 years old. After his marriage Mohammed gave up business, thinking himself rich enough, and for 10 years was chiefly occupied with his family, having by Kadijah, notwithstanding her advanced age, 8 children, 4 girls and 4 boys, who died young. When 35 years old, he settled the dispute of the chiefs of Mecca, who quarrelled as to who should restore the black stone on the rebuilding of the Caaba. From the 35th to the 40th year of his life Mohammed frequently resorted to a solitary cave of the neighboring Mt. Hara, to give himself entirely up to religious contemplations. There, amid spasmodic convulsions, he had the first vision, in which the angel Gabriel appeared to him and commanded him to recite what he (the angel) said. The day and the month when this beginning of his mission occurred are not known; common tradition refers them to the 27th day of Ramadan. Mohammed and his wife were troubled as to the nature of his mission, whether it came from an angel or from an evil spirit; but Waraka, a Christian priest, who was a relative of Kadijah, acquainted them with the means of testing this, and the application of the test convinced them that it was a holy angel. The revelations continued henceforth without interruption to the end of his life. They were dictated by Mohammed to several secretaries, committed by his adherents to memory, and after his death collected and written down. (See KORAN.) During the first 8 years

of his mission only the relations and friends of Mohammed were called on to acknowledge him as a prophet, and the whole number of believers (*Moslemis* or *Moslems*) amounted scarcely to 40, among whom were Abubekr and Ali. In the 4th (according to others the 5th) year of his mission he came forward publicly in compliance with a special commission, and proclaimed himself a prophet, but met only with imprecations and maltreatment. The Koreishites became greatly exasperated at him, and even the position of his followers became so dangerous that Mohammed advised them to emigrate to the country of a Christian prince of Abyssinia. A plot of his enemies against his life ended in the sudden conversion of Omar, who had undertaken to assassinate him, and who now became the staunchest of his adherents. To protect him from further attempts on his life, he was removed by his uncle Abu Taleb to a fortified castle outside of Mecca, where he remained 3 years. During this year an entire Christian caravan from Nadjran, and an exorcist who offered to relieve Mohammed from the devil, were converted. The Koreishites outlawed him with his friends, and affixed a document to that effect on the walls of the Caaba. When the interdict, after the expiration of 3 years, was removed, Mohammed returned to Mecca; and soon after, in the 10th year of his mission, he lost his uncle and protector Abu Taleb, who died as an unbeliever, having never acknowledged the mission of his nephew. Three days later he also lost his wife Kadijah, during whose lifetime he had not taken other wives; after her death he was married several, 9 of whom survived him. After the death of his uncle, Mohammed was again expelled from Mecca, and also from Tayef, whither he fled for safety; but soon he reentered Mecca, greatly strengthened by the celebrated journey to heaven, where he had been saluted by God as the most beloved of his messengers. His relation of the journey increased, however, the exasperation of his enemies, and even caused the apostasy of some of his adherents. Soon after an event of the highest importance occurred. Some pilgrims from Yathreb, belonging to the tribe of Khasradj, were converted in 621 to a belief in Mohammed, and on their return propagated the doctrines successfully at home. In 622, fewer than 78 Moslems from Yathreb appeared at Mecca, and concluded with Mohammed a treaty offensive and defensive. In September of the same year, in consequence of a new plot against his life, Mohammed fled to Yathreb, whither the Meccan believers, 45 in number, partly preceded him, and partly soon followed him. On his way he also converted the tribe Beni Sahm. The arrival at Yathreb established the new faith on a firm basis, and not without reason therefore the era of the Moslems began with the flight of the prophet, the Hegira. Moreover, the name of Yathreb was changed into Medinet el Nabi, "the city of the prophet" (Medina). Mohammed at first endeavored to gain

over to his religion the numerous Jews who lived in Arabia, and therefore made to them important concessions; but when he failed in this scheme, he not only rescinded the concessions, but became an irreconcilable enemy of all the Jewish tribes. During the first year of the Hegira he built a mosque at Medina, instituted a number of religious rites, and proclaimed war against the unbelievers as the heaven-ordained means to spread the true religion. He commenced this sacred war at once with attacks on the caravans of pilgrims, which led in the following year (623) to an engagement between 314 Moslems and 600 Meccans, who had been called by Abu Sofian, the chief of Mecca, to his aid. The Moslems remained victors, made many prisoners, and received for them a heavy ransom. In the following years Mohammed suffered many reverses; he was defeated by the Koreishites in the battle of Ohod (624), and besieged in Medina (627), and even among his followers a party was stirred up against him. To restore his reputation and influence, he determined to organize a large pilgrimage to Mecca, but was compelled by a dream to start when he had collected only 700 men. The Meccans prevented him from entering the city, but at last concluded a truce for 10 years, with the promise that the following year he would be admitted to the city as a pilgrim. To divert the discontent of his fellow pilgrims, he undertook with then another war against several Jewish tribes, in which he was on the whole successful; yet a Jewess, Zainab, to revenge the death of her relatives, prepared for him a poisoned lamb, which, as he firmly believed, destroyed his health. At this time the plans of Mohammed for the spreading of his religion assumed wider dimensions. He sent written demands to the Persian king Chosroes II., the Abyssinian king, the emperor Heraclius, the governor of Egypt, and the chiefs of several Arab tribes. Some received the ambassadors courteously, but Chosroes tore up the letter, while the people of Muttah even killed the ambassador. In a war undertaken to revenge this murder the troops of Mohammed fought a desperate battle at Muttah, in which Khaled, a new convert, highly distinguished himself, and was consequently termed by Mohammed "the Sword of God." He was successful in punishing the Meccans, who had broken faith with him; they were compelled, in order to save themselves, to acknowledge him as a sovereign and a prophet. The possession of Mecca decided the victory of the new religion in Arabia, and Mohammed was happy enough to see, notwithstanding some more temporary reverses, the subjection of a majority of the inhabitants of Arabia to his rule and to his religion. He himself returned to Medina, where he received in the 9th year of the Hegira deputations from various tribes who announced their submission. Feeling now sufficiently strong, he proclaimed a holy war against the Byzantine empire; but this proved a complete failure, he being obliged to

return to Medina amid the reproaches of the soldiers. In the following year Mohammed made the last pilgrimage to Mecca at the head of at least 40,000 pilgrims, in order to proclaim there orally the most important laws and doctrines of his religion. The rites of this pilgrimage have ever since been regarded as the standard rule for the pilgrimages of the faithful. Three months after his return to Medina, he was taken seriously ill. When his condition grew worse, he called all his wives together, and requested that he might be allowed to remain in the house of Ayesha, his favorite, which adjoined the mosque. He himself announced in the mosque the approach of his death, and promised to ask God's grace on behalf of all who would confess their transgressions. During the last days of his life he gave liberty to his slaves, caused 7 denars to be distributed among the poor, and prayed: "God support me in the agony of death." He expired in the arms of Ayesha, his last words being: "Yes—I come—among my companions on high." After a long dispute respecting the place of his interment, he was buried in the house in which he died. This spot lies now within the enlarged mosque, where it is annually visited by numbers of pilgrims. His only surviving child was Fatima, the wife of Ali, and the ancestress of all the sherifs or nobles of the Mohammedan world.—Mohammed is said to have been of middle stature, and to have had a strong beard and thick hair, a noble mien, a brown and lively complexion, a brilliant eye, a modest look, and white teeth. He had great natural eloquence, a keen intellect, and an overwhelming fluency, and was courageous and intrepid in dangers from which other men are used to shrink. Marital love he regarded as one of the greatest incentives to devotion, though the wish to have a son to succeed him has been alleged by some writers as the reason why he took so many wives. His only male issue, Ibrahim, died at the age of 15 months, and his loss drew from the prophet an extraordinary outburst of grief. In his infancy as well as in after life he was afflicted with epileptic attacks, which at first were considered by himself and by his enemies to be the effect of demoniacal possession. The same spasmodic convulsions accompanied him while he received his revelations. "Then," as a Mohammedan historian says, "the sweat fell from his forehead during the coldest weather, his eyes became red, and at times he roared like a young camel." Christian biographers have often inferred from this that Mohammed was really possessed of a devil, and that the mystery which envelopes the revelations of Mohammed can be solved only by the assumption of satanic influence. Mohammed was acquainted with the doctrines of both the Jews and Christians, but charged them with having corrupted their Scriptures. How he obtained this knowledge, and to what extent he possessed it, has not yet been entirely cleared up. He attributed to both of them doctrines which they do not hold, but most of these statements may rest on the an-

thority of the apocryphal books of the ancient Christian church.—Before the 12th century it was hardly understood in the West that Mahomet was a man, and not a pretended divinity, and still earlier he was known as Maphomet, Baphomet, or Bafum, and believed to be a false god to whom human sacrifices were offered. Later it was common among Christian writers to represent him as a conscious impostor. This opinion has now but few representatives, especially since Möhler and Carlyle in his "Hero Worship" have shown that it is hardly reconcilable with the devotion which appears in his life, and with the revolution effected by him.—Among the Mohammedan biographies of the prophet, those of Wackidi, Hishani, and Tabari are the most important; while later historians, as Abulfeda (formerly considered the chief authority), are now regarded as having no historical weight. Among the best European and American biographies of Mohammed are those of Maraccius (Padua, 1698), Gagnier (Amsterdam, 1732), Hammer-Purgstall (Leipsic, 1837), Weil (Stuttgart, 1848), George Bush (New York, 1882), Washington Irving (New York, 1852), A. Sprenger (Allahabad, 1852), Muir (London, 1858), and Arnold ("Ishmael, or a Natural History of Islamism," London, 1859).

MOHAMMED II., a Turkish sultan, surnamed **THE GREAT** and **THE VICTORIOUS**, born in Adrianople in 1430, died at Teggjar Zair, a small town in Asia Minor, in May, 1481. He was the eldest son of Amurath II. by a Christian princess of Servia, and succeeded him in 1451. He began his reign by a general reformation of the laws of the empire, and by calling to a severe account the treasurers and other officers of his father. He then led an expedition into Asia against the sovereign of Caramania, who had invaded the Turkish dominions, and who was speedily reduced to submission. He next turned his arms against Constantinople, which he invested in April, 1453, with a large fleet and an army of 800,000 men. After a siege of 58 days the city was taken by storm, May 29, and for 8 days given up to pillage and massacre. Having determined, however, to make Constantinople his capital, to attract population thither, the sultan proclaimed religious toleration and various privileges and immunities to the inhabitants. These measures soon rendered the city populous and flourishing. Mohammed next, in 1454, completed the conquest of Servia, which had been left unfinished by his father. But in 1456 he was baffled by the great Hunyady in the siege of Belgrade, from which the Turks were repulsed with the loss of 25,000 men, while the sultan himself was severely wounded. He next turned his arms against the Morea, which was still held by two Greek princes, Demetrius and Thomas, the latter of whom made a gallant though finally unsuccessful resistance, which led Mohammed to remark that he had found among the Greeks many slaves, but no man except Prince Thomas. The conquest of the Morea was completed in 1460, with the exception of some fortified seaports

held by the Venetians. In the following year the little kingdom on the S. shore of the Black sea, called the empire of Trebizond, was subjugated in a short campaign, and its ruler the emperor David Comnenus put to death with all his family, except the youngest son, who became a Mohammedan, and a daughter who was placed in the sultan's harem. Wallachia was next invaded and made tributary, and most of the islands of the archipelago were subjugated. The prince of Mitylene defended the capital of the island for a month, and finally was induced to surrender on condition of receiving an equivalent province; but Mohammed, faithless to his promise, kept him a while in prison, and then put him to death. The Christian powers, alarmed at his progress, agreed in a conference held at Mantua to enter on a new crusade against the Turks; but the internal difficulties of the European kingdoms prevented the execution of this scheme. The famous Scanderbeg, prince of Epirus or Albania, gave the first serious check to the triumphs of Mohammed by defeating several armies sent against him under Turkish generals of reputation. The sultan at length invaded Albania in person with an army computed at 200,000 men, and laid siege to Scanderbeg's capital, the city of Croia; but his camp was so harassed by Scanderbeg's assaults, that at length after great losses he was forced to retreat. In the following spring he renewed the attempt to take Croia, but was again forced to withdraw to his own dominions. Scanderbeg, however, died in 1466, and Albania, which had been preserved only by his valor and military genius, soon became a Turkish province. During the war with Scanderbeg the sultan was also engaged in hostilities with the Hungarians and the Venetians. From the latter he conquered Negropont in 1470, after a long siege in which he lost 40,000 men; and though the governor of Chalcis, the capital, surrendered upon condition of personal safety, he was put to death, as were all the rest of the captives. The Venetians now entered into an alliance against the Turks with Pope Sixtus IV., the kings of Naples and Cyprus, the grand master of Rhodes, and the shah of Persia. The fleets of the Christian allies attacked the coasts of the Turkish dominions and burned Smyrna and other places, while the Persians on their part invaded the eastern part of the empire in great force, and defeated Mohammed's eldest son Mahatpha in a pitched battle near the Euphrates. Mohammed himself, with an army of 300,000 men, encountered the Persians in Armenia, and was defeated with the loss of 40,000 men. In a second battle, however, he was victorious, and the Persians suffered such severe losses that they withdrew from their alliance with the Christian princes and concluded a peace with the sultan in 1474. In the following year Mohammed wrested Kaffa and several other parts of the Crimea from the Genoese, and made the khan of the Crim Tartars tributary. In 1478 the Venetians treated for peace, and agreed to

give up Lemnos, Scutari, and other strong places, retaining several fortresses in the Morea, and paying a tribute for the liberty of trading in the Black sea. In the following year Mohammed sent an army of 80,000 men to besiege Rhodes, which was defended by the knights of St. John with brilliant valor for upward of 3 months, when the Turks after sustaining immense losses raised the siege. At the same time another of the sultan's armies invaded Italy and took the city of Otranto, which was recovered in 1481 by a general effort of the Italian states, aided by Spain, Portugal, and Hungary. The sultan was preparing to renew the attack on Rhodes when he died, not without suspicion of poison, after an illness of 8 days. Mohammed II. was one of the ablest of the Turkish sultans, and is said to have conquered 2 empires, 12 kingdoms, and 200 cities. He is thus described by Richard Knolles in his "History of the Turks" (1610): "He was of stature low, square set and strong limbed. His complexion was sallow, his countenance stern, and eyes piercing, though a little sunk. His nose was so high and crooked that it almost touched his upper lip." Collections of his letters translated into Latin have been published at Lyons (1520), Basel (1554), Marburg (1604), and Leipsic (1690).

MOHAMMED IV., a Turkish sultan, born in 1642, died June 22, 1691. In 1648 he succeeded his father Ibrahim I., who was deposed and strangled by the janizaries. Mohammed Kuperli or Kuprili, an Albanian of eminent ability, was made grand vizier. To him, and to his equally distinguished son who succeeded him, the reign of Mohammed IV. owes all its celebrity. The sultan himself had neither talent nor energy, and cared little for any thing but hunting, in which he spent most of his time, and lavished vast sums. The empire at his accession was in the utmost confusion, but Kuprili restored order by promptly putting to death the leaders of sedition. In 1644, a Maltese vessel having been allowed by the Venetians to carry a Turkish vessel as a prize into a port in the island of Candia, which was then in their possession, Sultan Ibrahim had declared war against the republic, and in the following year the Turkish forces had conquered the greater part of Candia. This war continued after Mohammed's accession, and was not for some time prosecuted with much spirit by the Turks, Kuprili being wholly occupied in reestablishing domestic tranquillity. The Venetians defeated the Turkish fleet near Scio, June 24, 1651, and destroyed a second fleet, June 26, 1656, and shortly afterward captured the islands of Lemnos and Tenedos, which however the Turks regained in the following year. The contest with the Venetians continued with various fortune till 1667, when Achmet Kuprili, one of the greatest of Turkish generals, who had succeeded his father as grand vizier in 1664, undertook the siege of the city of Candia, which he prosecuted with vigor for 2 years and 4 months, when, after a defence which enlisted the sympathy of all

Christendom, the Venetian commander Morosini was compelled to capitulate, Sept. 6, 1669, while at the same time peace was concluded between Venice and Turkey. In 1660 war had broken out with the emperor Leopold I. of Austria, and for some time the Turks had been highly successful in Hungary. Germany, France, and Italy combined to check their progress, and Montecuculi, the general of the allies, gained a brilliant and decisive victory over them, Aug. 10, 1664, at St. Gothard on the Raab, which was immediately followed by the treaty of Temesvár, which put an end to the war. In 1672 the sultan declared war against Poland, invaded that country in person, and took Kamieniec. A treaty unfavorable and ignominious to Poland was agreed to by King Michael; but the diet refused to ratify it, and the grand marshal of the kingdom, the heroic John Sobieski, continued the war, and in 1678 gave the Turks a total defeat at Chocim, and in 1676 obtained from them an honorable peace. An insurrection of the Hungarians under Tökölyi tempted the sultan in 1682 to again make war upon the emperor; and in July, 1683, an army of 300,000 Turks, commanded by Kara Mustapha, invested Vienna. The emperor fled with his family to Lintz, and all Europe awaited with anxiety and dread the result of the siege. The city was in the last extremity when Sobieski and Charles of Lorraine came to its relief, and on Sept. 11 attacked and totally routed the Turks, who suffered immense losses. After this great defeat the Turks met with nothing but disasters. Germany, Poland, Russia, and Venice combined against them; and on Aug. 12, 1687, Charles of Lorraine gave them a terrible defeat at Mohács, which was followed by the loss of Transylvania and other provinces. These misfortunes excited great discontent in the Turkish army, which at length broke into mutiny at Belgrade, and, marching to Constantinople in the latter part of 1687, dethroned the sultan and raised his brother Solymán III. to the throne. Mohammed was kept imprisoned till his death.

MOHAMMED ALI. See MEHEMET ALI.

MOHAMMED BEN YUSSUF. See AL-GHALIB-BILLAH.

MOHAMMEDANISM, the name commonly given in Christian countries to the creed established by Mohammed. The followers of the creed themselves neither use nor acknowledge the name. They call their creed Islam, which means "full submission to God," and choose for themselves the name Moslem, or "the people of the Islam." Mohammed designated himself as the restorer of the pure religion revealed by God to Abraham. As the messenger of God he required his pagan countrymen to leave their idols and adopt the worship of the one true God; of the Jews, to exchange the law of Moses intended for only a limited period for the new and final revelations given to him; of the Christians, to cease worshipping Christ as God, as inconsistent with the idea of monotheism and with the true doctrine of Christ himself.

The doctrines of Mohammedanism may in large measure be traced to the national religion of the Arabs before Mohammed, and to those forms of Judaism and Christianity which existed in Arabia at the time of Mohammed. To what extent Mohammed borrowed from these three sources severally, is a question which was until recently involved in the greatest obscurity, but which the profound researches instituted during the last 20 years have begun to clear up. (See Geiger, *Was hat Mohammed aus dem Judenthum aufgenommen?* Bonn, 1883; Gerok, *Versuch einer Darstellung der Christologie des Koran*, Hamburg, 1889; Möhler, *Ueber das Verhältniss des Islam zum Christenthum*, Ratisbon, 1839.)—The sayings of Mohammed relative to his religion were collected in the Koran, which is recognized by all Mohammedan sects as their rule of faith and morals. But the great majority of the Moslems recognize, in addition to the Koran, the Soonna, or traditions, embodying the expressions, occasional remarks, and acts of Mohammed, which are traced back to his companions, his wives, and the first caliphs. Not only do they regulate, conjointly with the Koran, the doctrines, rites, and ceremonies of the Mohammedans, but the interpretation of the Koran is determined by them. There is much uncertainty among the Moslems regarding them; some sects, as the rationalistic Montasales, and the extremists among the Sheeahs, reject the Soonna altogether; the moderate Sheeahs acknowledge a tradition, but differ from the Soonnees respecting its extent. (See SOONNA, and SHEEAHS.) Among the Soonnees 4 orthodox schools were distinguished, all established between 740 and 840. They were called, after their founders Hanifa, Malek, Shafei, and Hanbal, the Hanifites, Malekites, Shafeites, and Hanbalites. The 1st and 4th were of little influence; the 2d prevailed in northern Africa and Spain, and the 3d in the eastern countries. Their differences were not in doctrines, but in discipline only. The two largest and most influential collections were made by Bukhari (died 869) and Abu Moslim. An extract from these two and some later collections was made by Hosein ibn Masud (died 1122), under the title *Masabih* (lights). It was translated into English, together with a commentary (*Mishcat*) by Wadi-eddin Abu Abdallah Mahmoud, who lived about 1169, by A. N. Mathews (*Mishcat ul Masabih, or a Collection of the most Authentic Traditions*, 2 vols., Calcutta, 1809). Most of the traditions received by the Sheeahs are contained in the books of *Hayat ul Kulub*, *Hag ul Yaqin*, and *Ain ul Hayat*, written by Mullah Mohammed Bakir Majlisi, a famous Persian divine, who lived about 1650, and which were printed in Teheran in 4 vols. fol. In the 8th and 9th centuries the rationalistic school, called by their opponents Montasales or Separatists, gained great strength and influence. Their chief seat was at Bassorah, where they formed an association of rationalistic scholars. They maintained the absolute self-determination of man, denied the eternity

of the Koran, and also rejected the reality of the divine attributes so far as to divest God of all those characteristics which are the expression of a personal existence. In the 10th century an orthodox school of scholasticism regained the ascendancy, especially through the efforts of El Ashari, the father of the later orthodox theology; and from this time the doctrines and the ethics of the prevailing denomination underwent no other considerable change. The gradual development of Mohammedan doctrines, and their relation to the Koran, are still subjects of controversy. We give an outline of the system of doctrines and ethics which generally prevails.—The Mohammedans have no general confession of faith, except the one: "There is no God but God, and Mohammed is his prophet;" to which the Sheeahs add: "and Ali is the vicar of God." The arrangement of the system of doctrines and the division into chapters varies greatly with different writers; but a work entitled "The Fundamental Doctrines of Neseef" (died 1142) is particularly esteemed. Every doctrinal work begins with the doctrine of God. He is one, spiritual, eternal, existing of himself. The attributes of wisdom, omnipotence, and mercy really belong to him. The word (which is read in the Koran) is eternally in him, but without sound. The Koran is the uncreated word of God. The world is not eternal, but has been created in the course of time by God. The accounts of the creation and of the prophets greatly resemble those of the Old Testament. Adam is the first, Mohammed the last prophet. The prophets were saints, and have proved their mission by miracles. The heavenly books—the Pentateuch, the Psalms, the Gospels, and the Koran—have been communicated to men by the hands of the prophets. Mohammed before his death really ascended to heaven. For the observers of the laws proclaimed by the prophets there is a heaven, and for the transgressors a hell, both of which are fully described in the Koran, about one sixth of that book being filled with details on this subject. According to the common view of the Moslems, the passage of man into the other world takes place in the following manner: The dead are subjected by the angels Munkir and Nakir to an examination, which is followed by an examination before God himself; the former is greatly feared. The dead will rise again; the balance in which they are weighed, the book in which their deeds are noted down by the angels, and the bridge Sirat, as thin as a hair, which is stretched over hell, are, according to common opinion, more than mere images. Paradise and hell are created, but will never end. Many prominent theologians assume the existence of an intermediate state for noble unbelievers (pagans). The faithful will not remain in hell for ever, and the prayer for the dead is as useful as that for the living, and the intercession of Mohammed is of special efficacy. Before the end of the world many important phenomena are to take place. The adversary of all true religion ("the liar") will come. God

and Magog will rise again, but Jesus the son of Mary will aid in the final triumph of the Islam. Over the fate of man rules the unchangeable will of God. The freedom of man in choosing between good and evil is asserted, but without mitigating the doctrine of predestination which borders upon fatalism. An essential branch of Mohammedan theology is its pneumatology, with regard to which it is difficult in many instances to say how much belongs to the Koran alone, how much has been added by the Soonna, and how much is merely popular belief. The first among the angels are the bearers of the divine throne; next comes the Spirit; next are the archangels Israfil, Gabriel, Michael, and Azrael; the cherubim; the angels who in military order celebrate the praises of God in the seven heavens; the recording angels, who write in a book the merits and sins of men; the guardian angels, who watch over individual men (every believer has 160) and things. Eblis, the devil, fell through pride and disobedience, and was expelled from paradise; but at his request God gave him a respite until the days of the resurrection. Where he abides until then is not stated in the Koran, but he is declared to be the author of all bodily evils and of all anti-Moslem impulses, sentiments, and movements, but of sin only so far as it is not consistent with Islamism. The djins or genii are a kind of link between the good and the fallen angels. Like the angels, they are created from fire; they rove over hill and dale, displaying their nature, especially at night; and so great is their swiftness, that one of them brought the throne of the queen of Sheba in the twinkling of an eye and placed it before Solomon. The work of Neseefi declares that the human race rank above the angels; only such angels as perform the services of apostles or prophets, like Gabriel, precede men; but on the other hand, the prophets from the human race are higher than the prophets from among the angels. The Islam assumes a human authority which teaches, commands, and forbids in the name of God; the men invested with this authority are called imams. The Islam inculcates most of those moral laws which are found in all religions. It emphasizes 5 commandments for specific times and circumstances, purification, prayer, fasting, alms, and the pilgrimage to Mecca. The Moslems are noted for their zeal in prayer. Every Moslem is bound to offer up prayer 5 times a day, at daybreak, at noon, in the afternoon, at sunset, and one hour and a quarter after it. In every town the faithful are invited to these prayers by a public crier, or muezzin, whose call contains short praises of God, a short confession of faith, &c. At the morning prayer he adds: "Prayer is better than sleep;" instead of which the Sheenhs say: "Come to the best work;" a difference which has given rise to bloody wars. After the call of the muezzin the Moslem may perform his prayers at any decent place, except that on Friday he is bound to perform them in the mosque. Beside these daily and weekly

devotions, they have two annual services in the two Beirams, which are movable festivals according to the computation of the Mohammedan year, and have reference to the fasting in the month Ramadan, and the *hadj* or pilgrimage to Mecca. They have also a kind of rosary devotion, consisting in the recitation of the 99 attributes of God followed by the name of God itself, according to 100 balls strung on a coral string. Charity is not strongly inculcated in general, but every Moslem who is not poor is obliged to give the 40th part of his property to the poor. The eating of pork is forbidden, as among the Jews; the same is the case with the drinking of wine. Mysticism and asceticism were early cultivated by the Moslems, and called forth Soofeeism, the monachism of the Islam, a phenomenon of the greatest importance for a right understanding of the true character and the bearing of their doctrinal system.—On their first promulgation the doctrines of Mohammed spread with amazing rapidity. In 12 years the whole of Arabia had embraced the Islam. Abubekr, the first caliph, declared war against all nations, especially against the emperor of Constantinople and "the great king of Persia," at that time the two most powerful monarchs of the world. The battle of Bostra opened Syria to the Arabs; and one of the first feats of Omar, the successor of Abubekr, was the conquest of Damascus. Soon afterward a battle near the lake of Gennesareth decided the fate of Syria. Jerusalem capitulated on easy terms, and with brief interruptions has remained subject to the Mohammedans, and is one of their three holy cities. One of the generals of Omar, Amru, completed the conquest of Egypt, and fairly commenced that of northern Africa. On the whole of the S. shore of the Mediterranean the Arabs met with little resistance; for, recognizing in the inhabitants people of the same stock, the introduction of their religion was greatly facilitated. Soon after the death of Omar, Persia was entered by Khaled, Irak or Assyria subdued and plundered, the Euphrates together with the gulf of Persia fell into the hands of the Arabs, and Ctesiphon and Faristan, whither the king of Persia had fled, were placed under Moslem domination. On the appointment of Ali to the caliphate those great internal struggles commenced, which have ever since rent the Mohammedan world, without however arresting its external extension. Moawyah, the rival of Ali, took possession of most of the Persian provinces, and established the Islam in Europe by getting a foothold in Sicily. He was still more fortunate in Africa, and from 697 the whole of N. Africa may be considered as the home of Islamism, Christianity, which once flourished in that country, being completely uprooted. At the beginning of the 8th century, the Mohammedans, under Tarik, crossed to Spain; one province after another was speedily subdued, and for 800 years the Saracens retained a dominion in that country. A few years later, Abderrahman with a force of 400,000

men entered Gaul, but they were defeated in the decisive battle between Tours and Poitiers by Charles Martel (A. D. 732), which put a final stop to their progress in western Europe. In Asia they advanced eastward in China and India; in the former country their progress was soon stayed, but in the latter they founded vast empires on the shores of the Indus and Ganges, which for a long time were strongholds of Islamism. Fresh energy was infused into the Moslem community by the accession of the Seljook Turks. Having been called to his aid by Mohammed ben Jubriel, they seized upon Persia, made themselves masters of a portion of the Byzantine empire, and established one of the seats of their government at Iconium or Konieh. Having withstood the repeated attacks of the Christian world during the period of the crusades, they were overrun by other Tartar tribes, also of Turanian origin, who passed over Persia, Armenia, and Asia Minor, and laid the foundation of the empire of the Ottomans, or Turks properly so called. Both the Seljooks and their successors, the Osmanlis, voluntarily received Islamism from the very people they conquered, the first instances of the peaceable conversion of an entire tribe to the Islam. The Ottoman rulers gradually undermined the Byzantine empire; Amurath I. entered Europe and made Adrianople his capital; Amurath II. left nothing to the Greek emperor but Constantinople; and Mohammed II. struck the fatal blow, taking Constantinople in 1458 after a siege of less than 2 months. The Ottoman empire, and with it the political power of the Islam, were now at their zenith; the Turks became for many centuries the terror of Italy, Hungary, and Germany, but Christendom ceased to suffer any considerable losses by their advance. On the other hand, the Christian nations began to conquer considerable portions of Moslem territory. Sicily had been lost before this period; in Spain the power of the Mohammedans had been on the decline for centuries, when in 1492 their last strongholds were taken; their powerful empires in India were entirely overthrown; Greece commenced its successful struggle for independence in 1821, Algiers was wrested from them in 1830; and the dependence of the Danubian principalities on the Ottoman Porte long since became merely nominal. Mohammedanism has continued, however, and still continues to make peaceable conversions in the interior of Africa. It is widely propagated in Soodan, and reigns in its strictest form in Bornoo; it prevails in the kingdoms of Ghana, Tokroor, Boocsa, Berissa, Wawa, and Kiama; and it is the established religion in Timbuctoo. A remarkable instance of the progress of the Islam is found in the history of the Mandingoes, N. E. of Sierra Leone. A century ago a few Mohammedans settled in that country; they established schools, in which Arabic and the Koran were taught; a community was formed, and after some time the whole country fell into their power. Great efforts are still made to proselyte

the pagans in the interior of Africa, and every year adds fresh tribes to the Moslem community. The Galla tribes are converted one by one; and in Malabar the Mohammedans purchase or procure children of the lower classes to bring them up in the "true faith." But while the Islam advances among races inferior to the original Mohammedans in point of civilization, its foremost representative among the great nations, the Ottoman empire, lives avowedly at the mercy of the great powers of Europe; Persia has felt the superiority of Russia, and Morocco has been defeated by Spain. The consciousness of this superiority of the Christian nations has been spreading for years throughout the extent of the Mohammedan world, and has gradually kindled those sentiments of fierce and uncompromising hostility to the Christian name, which have manifested themselves within the last few years in so bloody a manner in India, Arabia, northern Africa, and Syria. The approach of another holy war to revive the glory of the Islam is extensively preached; but those who stand highest among the Mohammedans and have seen and tasted the fruits of Christian civilization, no longer exhibit any confidence in the power of the Islam.—The total number of Mohammedans at the present time is estimated at about 160,000,000. In Europe they are almost confined to Turkey, and even there they form in the European part of the empire a minority of the population—6,000,000 out of 16,000,000. In Russia, European and Asiatic, they count 2,557,335 souls. They prevail in Asiatic Turkey, Persia, Afghanistan, Beloochistan, Arabia, and Tartary, and are largely represented in India and the Malay archipelago, and to some extent in China. In all their number in Asia is estimated by Dietrich at about 50,000,000. In Africa, the Islam is still the predominant religion in the entire north, and its rule extends far down eastward and into the centre of the continent; and it is believed that full one half, or about 100,000,000 souls may be set down as Mohammedans. In America and Australia they are not represented at all. More detailed accounts of the several national branches of Mohammedans will be found in the articles in this work devoted to the Mohammedan countries. On the cultivation of literature and art by the Mohammedans full information may be obtained in the articles on the Arabic, Persian, and Turkish literatures. One of the best treatises on Mohammedanism is that of Döllinger, *Muhammed's Religion und ihrer innern Entwicklung und ihrem Einflusse auf das Leben der Völker* (Ratisbon, 1845). See also Taylor, "History of Mohammedanism"; Mill, "Mohammedanism" (London, 1817); Arnold, "Ishmael, or a Natural History of Islamism" (London, 1859).

MOHAMMERAH, a town of Persia, on the left bank of the Euphrates, about 40 m. from the sea; pop. about 4,000. Its position gives it great commercial advantages. A canal connects it with the Karun and with the Persian

regions of Khuzistan, while by means of the Euphrates it communicates with Bassorah, Bagdad, and the Persian gulf. During the war of 1857 it was bombarded and taken by the British under Sir James Outram; after the conclusion of peace it was restored to the shah.

MOHAWK, a river of New York, which rises in Oneida co., about 20 m. N. from Rome, from which place it flows S. E. and E. through Herkimer, Montgomery, Schenectady, and Saratoga counties, falling into the Hudson at Waterford, 10 m. above Albany; length, 135 m. At Little Falls, Herkimer co., and "The Noses," Montgomery co., the river has forced its way through the mountain barriers, and flows through deep, rocky ravines; and at Cohoes, 1 m. from its mouth, it falls over a precipice 70 feet in perpendicular height. During its course it supplies great and valuable water power. The Erie canal and the New York central railroad follow its banks as far as Rome. Rome, Utica, Little Falls, Schenectady, and Waterford are the principal towns on its banks.

MOHAWKS, a tribe of American Indians, one of the six nations named collectively by the French the Iroquois. According to their own tradition, confirmed by those of other tribes, they were the eldest people in the league. They believed that they were liberated from subterranean confinement by Tareya-wagon, who guided them into the valley of the Mohawk; thence they passed to the Hudson and to the sea; but the valley in which they at first established themselves was the seat of their power from the discovery of the country until the American revolution. Their dominion extended from Lake Champlain to the head waters of the Susquehanna and the Delaware. Renowned above all the other nations for their skill as warriors, they carried terror wherever they went. Their forays were pursued as far as the Connecticut river, and their influence prevailed among the small independent tribes about the region of the present city of New York. During the French and Indian war they supported Sir William Johnson, following him in his most perilous expeditions, and aiding him in the contests of Lake George and Niagara. After his death they transferred their attachment to his family, and were forced to flee from their ancestral home to Canada. A few of them now reside with their brethren, the Senecas, Tuscaroras, and Oneidas, but the greater portion occupy lands appropriated for their use by the British government, at Brantford, on the Grand river of Canada West. To this place they followed their leader Thayendanegea (Joseph Brant) at the close of the revolution.

MOHEGANS, or MOHICANS, a tribe of American Indians, of Algonquin lineage, which inhabited during the early period of the Iroquois confederacy the country now forming the S. W. parts of New England, and that portion of New York E. of the Hudson. They retired before Iroquois conquests over the highlands into the valley of the Housatonic, but were early dis-

possessed of that territory by the whites. The few of them that now remain are scattered among other tribes.

MOHILEV, or MOGHILEV, a S. W. government of European Russia, bounded N. by Vitebsk, E. by Smolensk and Tchernigov, S. by Tchernigov, and W. by Minsk; area, about 20,000 sq. m.; pop. in 1856, 873,888. The surface is generally level, and the soil fertile. The climate is mild and dry. There are several small lakes and marshes. The principal river is the Dnieper. Bog iron is found in abundance.—MOHILEV, the capital, is situated on the right bank of the Dnieper, 212 m. W. S. W. from Moscow; pop. about 21,000, including many Jews. It is the seat of a Greek archbishop, and of the Roman Catholic archbishop and primate of Russia and Poland (in 1860, Wenceslaus Zylinski), and is also a favorite residence of the Russian nobility. It was taken by Charles XII. in 1708, and recovered by Peter the Great in 1709. A meeting of Joseph II. and the empress Catharine took place there in 1780. A portion of the Russian army was defeated there by the French, July 28, 1812.

MOHL, JULIUS VON, a German orientalist, naturalized in France, born in Stuttgart, Oct. 28, 1800. He studied at Tübingen and Paris, and in 1826 was appointed professor of oriental literature in the university of Tübingen, but was permitted to continue his studies for some time in Oxford and London. Subsequently, on being intrusted by the French government with the preparation of an edition of Firdusi's *Shah Nameh* for the *Collection orientale*, he relinquished his chair, and since 1832 has resided in Paris. In 1844 he succeeded the elder Burnouf as a member of the academy of inscriptions and belles-lettres, in 1845 Joubert as professor of the Persian language at the collège de France, and in 1852 Eugène Burnouf as inspector of the publication of oriental works in the *imprimerie impériale*, and as secretary of the Asiatic society, of which previous to that time he had been assistant secretary. His edition of Firdusi's celebrated poem is still in progress; the first 4 vols., in Persian and French, appeared between 1838 and 1854.

MÖHLER, JOHANN ADAM, a Roman Catholic theologian, born at Igersheim, Würtemberg, May 6, 1796, died in Munich, April 12, 1838. Having pursued his classical and theological studies at Mergentheim, Ellwangen, and Tübingen, he was ordained priest in 1819, and appointed in 1820 tutor in the seminary (*Wilhelmstift*) connected with the faculty of Catholic theology at Tübingen. His intention to devote himself to the study of classical philology was changed by an invitation of the theological faculty to lecture on theology. Before he entered on his new office, he was enabled by a stipend from the government to visit the principal Catholic and Protestant universities of Germany. On his return he commenced a course of lectures on church history, patrology, and canon law, which at once established his repu-

tation as an eminent theologian. At the same time he became a regular contributor to the "Theological Quarterly," published by the faculty of Tübingen, which was then and is still the leading journal for scientific theology in Catholic Germany. In his first articles he strongly sympathized with the reformatory movements which then agitated the Catholic church of S. W. Germany; he advocated the restoration of communion in both kinds, the abrogation of the use of Latin in the divine service, &c.; but in later years he abandoned these views, and the articles expressing them are not included in the collection of his minor works published by Dr. Döllinger (*Gesammelte Schriften und Aufsätze*, 2 vols., Ratisbon, 1839). In 1825 he published his first great work on "Unity in the Church, or the Principle of Catholicism according to the Church Fathers of the first three Centuries," which was regarded by Protestants and Catholics as one of the most important works of this century in defence of the Roman Catholic church, although not a few Catholic theologians were of opinion that Möhler had made too great concessions to Protestantism. Soon after the publication of this work (in 1826), he received a call as professor of theology to the university of Freiburg; and when he declined, the government of Würtemberg appointed him extraordinary professor at Tübingen. In 1827 he published his second important work, "Athanasius the Great, and the Church of his Times, especially in its Contest with Arianism" (2 vols., Mentz), for which the faculty of Tübingen conferred on him the title of D.D. His last and greatest work, "Symbolism, or Exposition of the Doctrinal Differences between Protestants and Catholics" (Mentz, 1832; 5th ed. 1838; English translation by Robertson), caused an extraordinary sensation in the theological world. The Protestant theologians conceded to him that he had succeeded in representing the Roman Catholic church in a more advantageous light than any other theologian since Bossuet; but they also maintained that he had not represented actual, but ideal Catholicism, and that he had misrepresented, at least partly, the doctrinal systems of the reformers of the 16th century. Some of the most distinguished Protestant divines wrote against him; especially Baur (*Der Gegensatz des Katholicismus und Protestantismus*, Tübingen, 1833; 2d ed. 1836), Marheineke, and Nitzsch. Möhler answered them, especially Baur, in his "New Investigations on the Doctrinal Differences between Catholics and Protestants" (Mentz, 1834). Baur replied again in the new edition of his work, but the continuation of the controversy was forbidden by the government, and Möhler was censured for having revived an obsolete contest. This turn of the controversy disgusted him with Tübingen, and when the Prussian government again offered him a professorship either at Bonn, Breslau, or Münster, he chose Bonn, but subsequently declined, when the archbishop of Cologne demanded that he should expressly retract his work on

"Unity in the Church," a condition to which he was unwilling to consent. In 1834 he accepted a call to the university of Munich, but his lectures were interrupted by sickness in 1836, and he never fully recovered. Two months before his death he wrote, on the imprisonment of the archbishops of Cologne and Posen by the Prussian government, his last article in the interest of his church, yet with such moderation and in language so dignified, that the Prussian government made a last and again unsuccessful effort to secure his services for one of the national universities. At the time of his death he was occupied in collecting materials for a history of monachism, fragments of which are published in the collection of his miscellaneous writings. This contains some other articles, which are counted among the most thorough works on their various subjects; especially on the relation of Islamism to Christianity, on the Pseudo-Isidore, on Gnosticism, on the history of the abolition of slavery, &c. A larger posthumous work on the Christian literature of the first three centuries was edited by Prof. Reithmayr of Marburg (*Patrologie*, vol. i., Ratisbon, 1839). A Catholic biography of Möhler, by Reithmayr, is added to the 5th edition of his "Symbolism." The best Protestant biography, which is that of Prof. Kling of Marburg, likewise classes him among the greatest theologians of the century.

MOHS, FRIEDRICH, a German mineralogist, born in Gernrode in 1774, died in Agordo, Lombardy, Sept. 29, 1839. He is known as the inventor of a new system of classification for minerals, which regards, in the collecting of species into higher groups, only their external characteristics. He left various works on mineralogical subjects.

MOIDORE, an old gold coin of Portugal, valued at £1 6s., or about \$6. There are also half and quarter moidores.

MOIGNO, FRANÇOIS NAPOLEON MARTEL, a French clergyman and scientific writer, born at Guémené, Morbihan, April 20, 1804. He studied under the Jesuits, became a member of the order, and in 1836 was appointed to the chair of mathematics in one of the Jesuit establishments in Paris. He became so deeply interested in scientific pursuits, that during the publication of his "Lessons in Differential and Integral Calculus" (2 vols. 8vo., 1840), being ordered by his superior to abandon his studies and accept the professorship of history and Hebrew in the university of Laval, he refused to obey, and after 4 years of dispute left the order. In 1841 he took charge of the scientific department of the *Époque* newspaper, and travelled throughout Europe as correspondent for that journal. He held similar positions on the staff of *La Presse* and of *Le Pays*. In 1848 he was appointed by M. Sibour chaplain of the lyceum of Le Havre. He has published a *Traité de la physique électrique* (1849); *Répertoire d'optique moderne* (1850); and essays *Sur le stéréomètre* and *Sur le saccharimètre* (1853). In 1851 he founded *Cosmos*, an encyclopædic review.

MOIR, DAVID MACBETH, a Scottish author, born in Musselburgh, Jan. 5, 1798, died in Dumfries, July 6, 1851. He was educated at the grammar school of his native town, and at the age of 13 was apprenticed to a medical practitioner named Stewart for a term of 4 years, after the expiration of which he attended medical lectures at the Edinburgh university, and obtained a diploma as surgeon in 1816. At first he intended to enter the army, but abandoned that plan, and in 1817 formed a partnership with Dr. Brown in Musselburgh. He worked hard in his profession, and spent his nights in literary pursuits, contributing both in prose and verse to Constable's "Edinburgh Magazine" and to "Blackwood." His serious poems were signed with the Greek letter Δ , and hence he was more commonly known to readers by the designation of Delta. In 1824 he published "The Legend of Genevieve, with other Tales and Poems," and in the same year began in "Blackwood" a serial novel, "The Autobiography of Mansie Wauch," which became very popular. His marriage took place in 1829. In 1831 he published a work on the "Ancient History of Medicine," and in 1843 another volume of poetry called "Domestic Verses," which contains some of his best known poems. In 1846 he met with an accident which made him lame for life. In 1851 the Edinburgh philosophical association invited him to deliver a course of 6 lectures on the "Poetical Literature of the Past Half Century," which were afterward published; and in the same year he made his 870th and last contribution to "Blackwood." A selection of his poetical contributions, together with a memoir by T. Aird, was published in 1852, and a new and complete edition of his works in 1857. Notwithstanding Dr. Moir's literary activity and celebrity, he adhered through life to his profession, having a large practice as the leading physician of Musselburgh, and writing only at odd moments and late at night. He died at Dumfries while on a tour of relaxation.

MOIRA, EARL OF. See **HASTINGS, FRANCIS.**

MOKANNA, or MOCANNA. See **ATHA BEN HAKIM.**

MOLA. I. **PIETRO FRANCESCO**, an Italian painter, born in Coldre, duchy of Milan, in 1612 or 1621, died in Rome about 1668. He was a pupil of Cesare d'Arpino and Albano. Establishing himself in Rome, he was much employed by Innocent X. and his successor Alexander VII., as also by Queen Christina of Sweden. Mola was a good colorist, and designed with correctness and taste. He was one of the best of the Italian landscape painters. II. **GIAMBATISTA**, a painter, sometimes erroneously called a brother of the preceding, born in France about 1620, died in 1661. He studied in Paris, and subsequently under Albano at Bologna. He excelled in landscapes.

MOLASSES (Fr. *mélasse*), the sirup which remains in the manufacture of brown sugar, after separating from the juice all the saccharine matter that can be made to crystallize to advan-

tage. "Sugar house" molasses is the sirup which remains in the conversion of brown into refined sugar, and contains too little cane sugar to repay its further treatment. By fermentation and distillation molasses mixed with the skimmings of the sugar boiling is made to produce rum. (See **SUGAR**).—The imports of molasses into the United States in the year ending June 30, 1859, chiefly from Cuba, reached nearly 83,000,000 gallons, valued at about \$5,000,000, mostly used for home consumption.

MOLBECH, CHRISTIAN, a Danish scholar and author, born in Sorø, Oct. 8, 1788, died in Copenhagen in June, 1857. He passed from the university of Copenhagen to a position in the royal library in 1804, of which he became chief librarian in 1823, when he became also professor of literary history in the university. In 1811-'18, and again in 1819 and in 1830, he travelled in the principal countries of Europe. From 1830 to 1842 he was one of the directors of the royal theatre, and as dramatic censor sought to raise the national stage to a more artistic character. The list of his writings, and of the reviews of them, in Erslew's *Forfatter Lexicon*, occupies over 11 closely printed pages. His work on bibliography has been translated into German, and is considered one of the best on the subject.—His son, **CHRISTIAN KNUD FREDERIK**, born July 21, 1821, has held an office in the royal library since 1848, and since 1853 has been professor of literature at Kiel. He has published lyric poems, a dissertation on statuary, a drama entitled *Dante*, and a lively narrative of travels in Spain.

MOLDAU, a river of Bohemia, which rises in the Bohemian forest, on the frontiers of Bavaria, flows in a S. E. direction as far as Rosenberg, and then pursues a N. course to Melnik, opposite to which town it falls into the Elbe. It is about 300 m. long, and for nearly half its course is navigable. Its chief tributaries are the Luschnitz, Sazava, Beraun, and Wattawa. The principal towns on its banks are Rosenberg, Budweis, and Prague. Vessels of 60 tons burden can ply on it to Prague.

MOLDAVIA (Turk. *Bogdan*), a country of Europe belonging to the Turkish empire, and now together with Wallachia forming the vassal state of the Danubian principalities. It is situated between lat. 45° and 49° N. and long. 25° and 29° E., and is bounded N. E. and E. by Bessarabia, from which it is separated by the Pruth, S. by the Bulgarian district of Dobrodja and by Wallachia, being separated from the former by the Danube, W. by Transylvania, and N. W. by Bukovina; area, including the lately reannexed districts of Bessarabia, 18,400 sq. m.; pop. in 1860, 1,400,000. It is traversed in the N. and W. by various offshoots of the eastern Carpathians, through which several passes lead into Bukovina and Transylvania. The principal rivers are the Danube, which during its short course on the S. boundary receives the waters of all the others, the Pruth, and the Sereth. The chief affluents of the Pruth are the Baglui and Shisha;

of the Sereth, the Bistritza, Moldava, Milkov, and Birlat. The largest lake is between the mouth of the Pruth and Sereth, in the S. E. corner of the country. Moldavia is rich in pastures, and produces wheat, maize, and other grains; excellent melons, which form a considerable part of the food of the peasantry; wines of various kinds, some of which rival those of Hungary; fruits, honey in great abundance, and several minerals, among which salt holds a prominent place. The forests contain bears, wolves, lynxes, and the aurochs, and yield excellent timber; the rivers abound in fish. Locusts often appear in destructive multitudes. The climate is rough in winter, but pleasant in summer. The inhabitants consist of Moldavians proper, of the Wallach race, Greeks, Armenians, Jews, Osángo-Magyars, Franks, and gypsies. The dominant religion is the orthodox Greek. The general language is the Wallachian, in which the preponderant Latin or Romanic element is largely mixed with Slavic, Turkish, and Tartar words. Agriculture, horticulture, and grazing are the principal occupations of the inhabitants, manufactures being almost entirely undeveloped, and commerce almost exclusively in the hands of the Greeks, Armenians, and Jews. Wine, honey, wax, cattle, hides, horses, and timber are the chief articles of export. The country is divided into Upper (or western) and Lower (or eastern) Moldavia, and subdivided into 18 *sinuts* (districts) and 64 *okols* (circles). The most important towns are Jassy, the capital and seat of the Greek archbishop, on the Baglui; Galatz, the chief emporium, on the Danube; Fokshany, on the Milkov; Roman, on the Sereth; Bakeu, on the Bistritza; and Botashany, on the Shisha. Moldavia is ruled by a hospodar (now sovereign of both the Danubian principalities), under the suzerainty of the Porte, and the protectorate of the great European powers. He is elected for life by the boyars or nobles, and limited by a divan or senate and a legislative assembly. He appoints the ministers. There is a civil, commercial, and canonical code. The military force consists chiefly of militia. The most influential class of citizens is that of the boyars, who enjoy ample privileges, and also represent the political life of the people. Education, in general, is still in its infancy. (For further details on the constitution and the financial and literary condition of the united principalities, see WALLACHIA, and WALLACHIAN LANGUAGE and LITERATURE.)—In ancient times the country, which at various periods of its history extended beyond its present limits, was occupied by the Getæ. Darius Hystaspes invaded it on his expedition against the Scyths. It was subsequently an object of contention between the Scyths and the rulers of Macedon. In the latter part of the 1st century it belonged to the Dacian kingdom of Decebalus. Parts of it were attached, after his defeat, to the Roman province of Dacia. During the great migration of northern nations it was successively invaded by the Goths, Huns, Bulgarians, and Slavic tribes.

The Avars became dominant in the 6th century, but had soon to yield to the Bulgarians and their allies. After a few centuries the Bulgarians were overpowered by the Khazars, Petchenegs, and others. The latter tribes successfully warred with the Magyars, but continual dissensions prevented the inhabitants of the country from forming a well organized state, and the introduction of Christianity in the 11th century was almost without effect. Wars with the Greeks depopulated the country, which was soon after invaded by the Cumanians. These were in their turn subdued by the Mongols. Toward the close of the 13th century the inhabitants consisted chiefly of disunited Tartar, Cumanian, Petcheneg, Greek, Italian, and Wallach elements. In the earlier part of the following century a new Wallach immigration took place from Hungary under Bogdan, who together with his son Dragosh succeeded in establishing a dynasty of waywodes known in history under the name of the Dragoshites. The country now received the name of Moldavia from the river Moldava. The Greek creed was made predominant. But conflicts for the succession, insurrections, conspiracies, fratricidal feuds of every description, combined with external wars against Russians, Lithuanians, Poles, Crimean Tartars, Hungarians, Wallachians, and Turks, to make the long reign of the Dragoshites one of the bloodiest in history. One of the most warlike princes of the period was Stephen VI., surnamed the Great, son of Bogdan II., who died in 1504; but his son and successor Bogdan III. was unfortunate in his war against the Hungarians and Poles, and having also suffered an invasion of the Tartars, he submitted himself to the suzerainty of the Porte. Bogdan's son, Stephen VII., leaned toward the Christian powers; but his successor, Peter VI., an illegitimate son of Stephen VI., allied himself closely with Sultan Solymán the Magnificent during his expedition against Vienna, receiving the acknowledgment of princely dignity in exchange for tribute. Moldavia was now a vassal province of the Ottoman empire, and soon after lost its eastern division, situated between the Pruth and Dniester, and now known as Bessarabia, which was constituted a separate Turkish province. This part was subsequently often reannexed and again detached. The suzerainty of the Porte little if at all ameliorated the condition of the distracted country. Civil wars, assassinations of the rulers, insurrections, depositions, and restorations were common events. For some time the boyars exercised the privilege of electing the waywodes. Later, however, the sultans were called upon to appoint them. Waywodes of various nationalities were now successively appointed, but their rule proved as inefficient in establishing a permanent condition of subjection, as it was distasteful to the boyars. One of the more distinguished foreigners was Basil Lupulu, a Greek of Epirus, who promoted civilization and science but was deposed in the middle of the 17th cen-

ury, during the latter part of which, as well as in the following period, Fanariote Greeks mostly succeeded each other under the title of hospodar or prince. The principal families from which hospodars were selected were those of the Cantacuzenos, Cantemirs, Ducas, Rakovitzas, Mavrocordatos, Ghikas, and Ypsilantes. Of neighboring states, Poland and Transylvania having lost their influence over Moldavian affairs, Russia now became the most important. Most of the Fanariote hospodars leaned toward it, some of them secretly conspiring with Peter the Great and his successors. In the Turko-Russian wars which now followed each other, Moldavia was a principal object of contention. Peter the Great was near perishing with his army on the banks of the Pruth in 1711. In 1737 and 1738 Moldavia was more successfully invaded by the Russians under Münnich. In the first Turkish war of Catharine II. it was occupied by Rumianzoff and Panin, and organized as a Russian province, but restored to Turkey by the peace of Kutchuk Kainarji (1774), which, however, secured to Russia a kind of protectorate. Soon after, Moldavia, which had in the meanwhile been robbed of various important places, converted into Turkish fortresses, also lost its northern district, the Bukovina, which was claimed on trivial grounds and annexed by Austria (1777). The same power afterward combined with Russia for a new attack on Turkey, and Moldavia again became a seat of war. Leopold II., the successor of Joseph II., terminated the war by the peace of Sistova in 1791, Catharine II. more advantageously by that of Jassy in the following year. The succeeding Turkish wars were closed by the treaties of Slobosia (1807) and Bucharest (1812), by the latter of which the czar Alexander gained Bessarabia. The Greek insurrection under Ypsilante was a source of terrible suffering to the province. The treaty of Akierman (1826) restored the right of electing hospodars, for 7 years, to a divan of boyars, the Porte retaining the right of confirmation, and Russia its protectorate. The subsequent war of 1828 again brought Moldavia, as well as Wallachia, into the hands of the Russians, who occupied it, under Kisseleff, even after the peace of Adrianople (1829), which excluded all Turks from a permanent abode in it, a new statute being elaborated by a commission of boyars. This being confirmed by the Porte, the Russian army left the principalities, and Michael Sturdza, a native boyar, was elected hospodar of Moldavia for life. To unite the two principalities, as an independent Dacian or Rouman state, became now the chief tendency of the national party. Sturdza often gave umbrage to the representatives of Russia, and a revolutionary outbreak in Wallachia in 1848 was again followed by a Russian occupation. A new treaty was concluded by the Porte and the czar Nicholas at Balta Liman in 1849, in consequence of which Sturdza resigned his office, and another boyar, Gregor Ghika, was elected hospodar for 7 years. The war of

1853 destroyed the new basis. The Russians again occupied the principalities, but the military events on the Danube and in the Crimea compelled their troops to evacuate them, when they were occupied by the neutral armies of Austria. The peace of Paris in 1856 referred the affairs of the principalities, which were to be united, to a conference at Paris of the representatives of the great powers, the Porte, and Sardinia, which, in Aug. 1858, finally agreed on a new plan of organization. Soon after Alexander Couza was elected hospodar for life in both principalities, which being an unexpected event, as two elections were anticipated in accordance with the protocol of the conference, led to new complications. The influence of France, however, prevailed, in favor of the tendency to national union, and the election was confirmed by the Porte, and acknowledged by all other parties. (See WALLACHIA.)

MOLE, the name of many insectivorous mammals of the family *talpida*, embracing several genera agreeing in having a stout, thick, clumsy body, without visible neck, no external ears, minute auditory foramina, very small eyes, short limbs, anterior much the broadest and largest, with strong claws, short tail, and soft, velvety, and compact fur. Moles are generally distributed over the earth, except in South America and within the tropics, though the genera are closely restricted within certain regions; thus *talpa* is found only in Europe and Asia, *scalops* and *condylura* in North America, *chrysochloris* in Africa, and *urotrichus* in Japan and N. W. America. In *talpa* (Linn.) the dentition is: incisors $\frac{1}{1}$, canines none, and molars $\frac{1}{1}-\frac{2}{2}$, the first of the molars representing a canine (the upper in front of the lower), and the last 8 tuberculate; by some writers the 4th tooth on each side in each jaw is called a canine, which would make the teeth equal in number and alike in kind in both jaws. The nose is lengthened, truncate at the point; feet 5-toed, the soles of the fore feet turned backward, with toes connected and strong claws. The European mole (*T. Europaea*, Linn.) is 5 or 6 inches long, with a tail of 1 inch; the fur is very fine, of a blackish color; the bones of the fore limbs are very short and strong, supported by firm clavicles, and ending in a shovel-shaped hand, strengthened by the elongated falciform carpal bone, armed with large claws, and moved by muscles of great power; the sternum is keeled for the attachment of the pectoral muscles, the principal ones employed in digging their burrows; the muscles of the head are also powerful assistants in loosening the earth as the animal pursues its underground passage, preparing the way by its pointed, movable, hog-like snout. The senses of smell, hearing, and touch are very acute, in accordance with its subterranean mode of life. The eyes are 2 black glittering points, of about the size of mustard seed, concealed and protected by the surrounding skin and hairs. The popular belief that the mole is blind is an error; the mole of Greece mentioned by Aristotle as blind is either

the species *T. caeca* (Savi), in which there is no visible ocular fissure, or perhaps a burrowing rodent or rat-mole (genus *spalax*, Guld.), in which the very small eyes are hidden under the hairy skin. The openings of the ears and mouth may be closed by membranous folds to prevent the entrance of earth; the vent is considerably prolonged upon the tail. For interesting peculiarities in the reproductive system, see article "Insectivora" in the "Cyclopædia of Anatomy and Physiology." The food of the mole consists of worms, insects, and tender roots, in search of which it burrows in the ground; these excavations also serve as a place of residence and as a highway of travel from one field to another; its abode is in some firm hillock in a secure situation, in which are 2 circular galleries communicating with each other, the chamber being excavated in the centre of the lower gallery; these communicate by intricate passages with the high road, through which the animal passes with considerable speed, though very slow-moving on the surface of the ground; the road is placed at a depth of from 4 to 14 inches, according to its exposure to pressure from above. The mole frequently comes to the surface for the purpose of getting rid of the loosened earth, thus forming the little heaps known as mole hills; it is very voracious, and is soon killed by hunger; it is active all winter, though at a depth of a foot or more, and in summer at night frequently seeks its prey at the surface; it is a good swimmer; when irritated it bites severely, and the males in the love season often engage in deadly combats. The colors vary somewhat, and individuals are seen of white, ash, or fawn color; the soft fur is manufactured into light robes and very fine hats, and has been employed for artificial eyebrows. This industrious miner is frequently very detrimental to cultivated lands, but the loss is more than counterbalanced by the destruction of noxious insects and weeds. Four or five young are produced at a time, twice a year, in spring and autumn. This mole is generally distributed over Europe and Asia.—The golden moles of Africa (*chrysochloria*, Lacép.) have incisors $\frac{3}{4}$, the middle lower ones small and narrow, and molars $\frac{7}{8}$ — $\frac{1}{4}$; the eyes are covered by skin, nose naked and leathery, fore feet 4-toed, with 4th toe very small, hind feet 5-toed, and no tail. The best known species (*C. Capensis*, Desm.) is of a brownish color with green and golden reflections; it inhabits the Cape of Good Hope, and has the form, size, and habits of the mole.—The star-nosed mole of North America (*condylura*, Illiger) has the end of the nose surrounded by 22 movable fleshy filaments, radiating in the form of a star, which serve as delicate organs of touch; the incisors are $\frac{3}{4}$, the upper middle ones broad, the lower ones procumbent, canines $\frac{1}{2}$ — $\frac{1}{4}$, molars $\frac{7}{8}$ — $\frac{1}{4}$; eyes very small; feet 5-toed; tail moderate, thinly haired. The *C. erikata* (Desm.) is about 4 inches long from tip of nose to base of tail, the latter being 8 inches more; it has the general

form of the moles; the hands resemble those of terrapins, and with the hind feet (considerably larger) are furnished on both surfaces with a covering of brown scales, with a horny tubercle on the inner edge of the soles; the under surface of the fingers is extended into fringed horny processes. The fur is rather coarse, of a sooty brown color; it is found in the northern parts of America from the Atlantic to the Pacific.—The most common American moles belong to the genus *scalops* (Cuv.), called also shrew moles from the resemblance of their dentition to that of the shrews; the incisors are $\frac{3}{4}$, canines $\frac{1}{2}$ — $\frac{1}{4}$, molars $\frac{5}{8}$ — $\frac{3}{8}$; in *scapanus* (Pomel), set apart for the Oregon and hairy-tailed moles, the incisors are $\frac{3}{4}$, canines $\frac{1}{2}$ — $\frac{1}{4}$, and molars $\frac{1}{2}$ — $\frac{1}{4}$. In the common mole (*S. aquaticus*, Cuv.) the teeth are 36, the eyes not covered by integument, tail nearly naked, and feet fully webbed; the color is dark plumbeous, with sometimes a brownish tinge, and the feet and tail are white; it is between 4 and 5 inches long, with the tail about an inch; it is found from Canada to Florida, and as far west as the Mississippi. The silver mole (*S. argentatus*, Aud. and Bach.) is a larger species of a silvery plumbeous color, found on the western prairies. The Oregon mole (*S. Townsendii*, Bach.) has 44 teeth; it is nearly black, with purplish or brownish reflections; it is about 5 inches long, with a tail of $1\frac{1}{2}$ in. The hairy-tailed mole (*S. Breweri*, Bach.) is dark plumbeous, glossed with ashy brown; it is about $5\frac{1}{2}$ inches long, and found in the New England and middle states.—The genus *urocyon* (Temm.) has incisors $\frac{3}{4}$, canines $\frac{1}{2}$ — $\frac{1}{4}$, and molars $\frac{5}{8}$ — $\frac{3}{8}$; the muzzle is prolonged into a cylindrical tube terminating in a naked bulb; tail short and hairy. A common species in Japan is the *U. talpoides* (Temm.), smaller than the common mole. A species (*U. Gibbii*, Bartsch) $2\frac{1}{2}$ inches long, occurs in Washington territory.

MOLE, LOUIS MATHIEU, count, a French statesman, born in Paris, Jan. 24, 1780, died Nov. 25, 1855. He belonged to a family which had long occupied distinguished places in the French magistracy. His father, President Molé, lost his life during the first French revolution, and the son passed most of his childhood with his mother in Switzerland and England. Returning to France in 1796, he studied at the central school of public works, afterward entered the polytechnic school, and in 1806 published his *Essai de morale et de politique*, in which he defended absolutist theories in politics with an ability which commanded immediate attention. Fontanes, editor of the *Journal de l'Empire*, presented him to Napoleon, who, anxious to identify with his government the influential names of the old monarchy, appointed the young author auditor and soon afterward master of requests in the council of state. In 1807 he represented the emperor in the grand sanhedrin of the Jews assembled to draw up a code of doctrine for their people, and in the same year he was made prefect of the department of Calvados d'Or. About this time he wrote an *éloge* in

ancestor Mathieu Molé, president of the parliament of Paris during the wars of the Fronde, the tenor of which was well fitted to further his prospects of advancement. He became councillor of state and director-general of bridges and roads, and in 1818 pronounced a glowing panegyric on the emperor before the *corps législatif*, for which he was rewarded in September of the same year with the post of *grand juge* (minister of justice), and the titles of count of the empire and commander of the order of *réunion*. While Napoleon was absent with the army, the count acted as one of the council of regency, remaining faithful to his post until the last moment, and attending the empress Maria Louisa in her flight to Blois on the approach of the allied armies to Paris in 1814. Released from his allegiance by the emperor, who advised him to serve the new régime as faithfully as he had served him, Molé gave in his adhesion to Louis XVIII., and was called to the municipal council of Paris. On Napoleon's return from Elba, he refused to sign the declaration of the council of state against the Bourbons, though he retained his office as director of bridges and roads and was made a peer of France. On the second restoration he was re-nominated to the council of state and confirmed in his peerage; but he never enjoyed the full confidence of Louis XVIII., and had but little influence in the government. Although he voted for the execution of Ney, he exerted himself to the utmost to save other victims of the royalist reaction. In May, 1817, he became minister of marine in the cabinet of the duke of Richelieu, and took an active part in all the measures of the administration. Resigning with the majority of his colleagues in Dec. 1818, he remained out of office until the accession of Louis Philippe, who appointed him minister of foreign affairs, Aug. 11, 1830. The ministry, formed by a coalition of parties in which Count Molé represented the bourgeoisie interest, fell to pieces in less than 8 months, the ostensible cause of rupture being the refusal of the king to dismiss Odilon Barrot from the prefecture of the Seine. In Sept. 1836, after the overthrow of the Thiers ministry, Molé returned to power as premier and minister of foreign affairs, at the head of a cabinet based on the principle of non-intervention in the affairs of Spain, and composed chiefly of *doctrinaires* and conservatives, with M. Guizot as minister of public instruction. By the exclusion of Guizot and the *doctrinaires* in the following April, he found himself the leader of the most conservative ministry of any since the revolution of 1830, and face to face with a powerful opposition, of which Thiers and Guizot were the recognized heads. He negotiated the marriage of the duke of Orleans, and procured an amnesty for political offenders; but several unpopular measures, such as the dotation of the duke of Nemours, and the proposed "law of disjunction," providing that when certain crimes had been committed by soldiers and civilians jointly, the former should be tried by

military and the latter by the civil courts, had prepared the way for the victory of the Thiers and Guizot coalition; and after twice dissolving the chambers, Molé was forced to resign, in March, 1839. In the following year he was chosen a member of the academy. At various times he was invited to form a cabinet, but did not succeed; and throughout his career he enjoyed the warm personal regard of Louis Philippe, who in 1837 conferred upon him the grand cross of the legion of honor. At the time of the revolution of 1848 he withdrew from public affairs, but without solicitation was chosen to represent the department of Gironde in the constituent assembly, where he placed himself among the leaders of the right. In this body, as well as in the legislative assembly, to which he was elected in 1849, he exerted no inconsiderable influence, although he seldom took part in debate. He was a member of the committee which framed the law of 1850 against universal suffrage, and was reckoned among the supporters of government until the course of the ministry began to run counter to the monarchical interests with which he was both by principle and hereditary association identified, when he went over to the opposition, and was one of those who protested to the mayoralty of the 10th arrondissement against the *coup d'état* of Dec. 1851. The close of his life was passed in retirement at his ancestral chateau of Champlâtreux. In politics Count Molé combined a certain proportion of liberal ideas with the high-bred tone and absolutist principles of the statesmen of the old régime. He belonged to the ultramontane party in religion, and was one of the staunchest supporters of the Roman Catholic church in France. A vast fund of historical information, a talent for debate, unaccompanied however by remarkable eloquence, industrious habits, and a grave, aristocratic bearing, gave him great influence in the chamber of peers; but, as Alison remarks, "he was better acquainted with France as it had been than as it was—a fault common to him with many aristocratic leaders, and which has led to many of the most unfortunate steps recorded in history."

MOLE CRICKET, a jumping orthopterous insect, of the family *achetada*, and genus *grylotalpa* (Latr.), meaning cricket mole. The European mole cricket (*G. vulgaris*, Latr.) has a most extraordinary and ugly form; it is nearly 2 inches long and $\frac{1}{4}$ of an inch wide, and of a dark brown color; the head, retractile within the prothorax, has 2 long and strong antennæ in front of its black reticulated eyes; the thorax is elevated and crab-like, covered with a velvety down; the wings, which when expanded are broad and triangular, when folded extend like 2 ribbons over the abdomen; the abdomen, soft and with 9 or 10 segments, has 2 filaments at the end as long as the antennæ; the fore legs are short, broad, and strong, the shanks being very wide, flat, and 8-sided, with 4 finger-like projections on the lower side, giving very much

the appearance and the digging powers of the hands of the mole, whence the generic name. The female lays 200 or 300 eggs in June in a gourd-shaped hollow in the earth, about 2 inches long, having a winding communication with the surface; the young are hatched in 5 or 6 weeks, and resemble black ants, not arriving at maturity till the 3d year; both young and old commit great ravages by feeding on the tender roots of grass, culinary vegetables, and flowers; they also eat insects and worms, and themselves furnish food for moles, lizards, snakes, and other insectivorous animals. The males emit a pleasing sound at night, at which time they are the most active. Rösel says this insect can push forward on a level surface a weight of 6 lbs. with its fore feet, indicating the power which it can exert in digging its subterranean passages. They rarely appear on the surface, but their presence may be known by the withered patches in the field and garden, and their retreats detected by the little hills of fresh earth, smaller than those of moles, which they throw up in soft and moist places. Late in the autumn they bury themselves deep in the ground, coming again to the surface in the warm days of spring. The surest way to prevent their depredations is to dig up the nests and destroy the eggs; other ways are to pour boiling water or oil into their holes. The American species (*G. brevipennis*, Serville) is about 1½ inch long, of a bright bay or fawn color, with the wing covers not ¼ the length of the abdomen, and the tips of the folded wings extending only ¼ of an inch beyond the covers. They have not yet proved very destructive in this country; if, as cultivation is extended, they should be injurious to vegetation, in addition to the above remedies, grated carrots or potatoes mixed with arsenic may be placed near their burrows, or swine be permitted to root them up. The *G. didactyla* (Latr.), having only 2 finger-like projections on the fore legs, has proved very destructive to the sugar cane in the West Indies and South America.

MOLESCHOTT, JACOB, a Dutch physiologist and naturalist, born in Bois-le-Duc, Aug. 9, 1822. He studied at the gymnasium of Cleves, Prussia, where Moritz Fleischer familiarized him with the philosophy of Hegel, and in 1842 went to Heidelberg, where Tiedemann and Delffs in chemistry. Physiology and anthropology became his favorite pursuits, though he continued to devote his attention to the Hegelian philosophy, and published in 1842 a Dutch translation of Karl Snell's *Philosophische Betrachtungen der Natur*. The university of Haarlem conferred in 1844 its principal medal upon his *Kritische Betrachtung von Liebig's Theorie der Pflanzenernährung* (Haarlem, 1845); and on Jan. 22, 1845, he obtained his diploma as doctor of medicine, surgery, and midwifery from the faculty of Heidelberg, when he produced a dissertation entitled *Ueber den Bau der Lungen*. In May, 1845, he returned to his native country, establishing himself as a physician

at Utrecht. At the same time Mulder's celebrated chemical laboratory in that city gave him opportunities of experimental labors in the science, while he continued to pursue physiological investigations in concert with his friend Donders, the results of which were embodied in the *Holländische Beiträge zu den anatomischen und physiologischen Wissenschaften*, by Van Deen, Donders, and Moleschott (Düsseldorf and Utrecht, 1848). The study of the writings of Feuerbach and of his countryman Schelling brought him into conflict with the system of Hegel, and he gained the conviction that the philosophy of the universe can only be satisfactorily explained by the light of the natural sciences, and not by that of abstract metaphysical speculation. With a view of disseminating these principles, he returned to his *alma mater* in 1847, at first teaching physiological chemistry and dietetics, and afterward experimental physiology, anthropology, and general and comparative anatomy. His activity as a lecturer and writer inaugurated in Heidelberg a new era in the study of physiology. According to Moleschott, man is a chemical compound, and his condition is determined by his food and other external circumstances; and hence he regards the study of dietetics as a principal step to the formation of a more comprehensive system of anthropology. These views, which he illustrated by the latest investigations of all branches of modern science, have caused him to be regarded as a materialistic philosopher, although he differs from Hegel only in the interpretation of the organic nature, which he regards as indivisibly united with spiritual forces. With Moleschott all phenomena of the universe are animated, spiritual as well as by material life, and have been so from the dawn of time. The fear of the advocacy of his views brought him into collision with the government of Baden, and a year after Kuno Fischer's dismissal on account of his pantheistic principles, Moleschott's writings were also arraigned (1853); but on that occasion he was supported by the medical faculty of Heidelberg, and the physiological laboratory which he had founded in the summer of that year, as an institution independent of the university, continued to be crowded with students. In 1854, however, the government renewed its persecution, and he was accused of propagating precepts dangerous to religion and morality. He protested against this imputation, and declared it to be the highest moral duty of a teacher to expound truth with the utmost freedom and independence. At the same time he relinquished his place in the university. On Aug. 6 he received a brilliant ovation from his principal pupils, who in vain called upon the government to specify the charges against the professor, and who continued to attend his lectures in his private laboratory until the summer of 1855, when he removed to Zurich, and on June 2, 1856, assumed a professorship in the newly founded federal polytechnic school. He delivered a remarkable discourse, entitled *Licht und*

ben (Frankfort, 1856), of which a 2d edition appeared in 1857. He is still (1860) professor of physiology in that institution, and at the same time practises his profession. Dr. Moleschott has largely contributed to the *Zeitschrift für rationelle Medicin*, *Archiv für physiologische Heilkunde*, *Müller's Archiv*, *Natur*, &c.; and he founded in 1856 a new physiological review under the title *Untersuchungen zur Naturlehre des Menschen und der Thiere*, which is published at Frankfort-on-the-Main. Among his principal works are: *Physiologie der Nahrungsmittel, ein Handbuch der Diätetik* (Darmstadt, 1850; 2d ed., 1857-'8); *Lehre der Nahrungsmittel* (Erlangen, 1850; 3d ed., 1856); *Physiologie des Stoffwechsels in Pflanzen und Thieren* (Erlangen, 1851); *Kreislauf des Lebens: physiologische Antworten auf Liebig's chemische Briefe* (Mentz, 1852; 3d ed., 1856); and *Georg Forster, der Naturforscher des Volks* (1854; new ed., 1857). He has also translated into German from the Dutch Mulder's essay on chemical physiology, and is now (1860) said to be engaged on an elaborate work on anthropology.

MOLESWORTH, SIR WILLIAM, an English statesman, born May 23, 1810, died Oct. 22, 1855. He studied at Cambridge and Edinburgh, and afterward in Germany, made the tour of the continent, and returned to England in 1831. He was returned to parliament for East Cornwall in 1832, reëlected in 1834, and in 1837 was a member for the city of Leeds, but retired in 1841, and devoted himself to the study of politics and social economy. In 1850 he was returned to parliament by the borough of Southwark, and continued to represent that constituency until his death. He was known as a philosophical radical in politics, and on the rise of the free trade party gave his influence in favor of that measure. On the formation of Lord Aberdeen's ministry in Jan. 1853, Sir William accepted the office of first commissioner of public works; and in July, 1855, he was appointed to the secretaryship of the colonies, but survived his appointment only a little more than 3 months. His speeches in parliament in the years 1837, '38, and '40 had shown an intimate acquaintance with the colonial system of England, and the London "Times" called him the "liberator and regenerator of the colonial empire of Great Britain." He was a frequent contributor to various periodicals and reviews, particularly to the London and Westminster review, of which he was for some years editor and proprietor in conjunction with John Stuart Mill. He edited and published at his own expense the first collection of the complete works of Thomas Hobbes (16 vols. 8vo., London, 1839-'45).

MOLFETTA (anc. *Respa*), a fortified seaport town of Naples, province of Bari, on the Adriatic, 16 m. W. N. W. from Bari; pop. 17,000. It is the see of a bishop, and has a cathedral, several other churches, a college, and a castle. Linen and saltpetre are manufactured, and small coasting vessels are built. In the vicinity are numerous oval caverns arranged in tiers, one

of which, called the Pulo di Molfetta, is 1,400 feet in circumference and 112 feet deep. Nitre abounds in all the caverns.

MOLIÈRE, the assumed name of JEAN BAPTISTE POQUELIN, the greatest comic poet of France, born in Paris, Jan. 15, 1622, died there, Feb. 17, 1673. He was both the son and grandson of *valets de chambre tapissiers* to the king, and aided his parents in this trade, to which he was himself destined, till his 14th year. His grandfather had a taste for theatrical representations, and occasionally took him to the hôtel de Bourgogne, where Bellerose then acted in genteel comedy, and Gauthier-Garguille and Turpin in farce. It was noticed that he always returned sad, thoughtful, and disinclined to business. The result was that he obtained permission to engage in study, and was sent in 1637 to the Jesuit college of Clermont in Paris, where he remained 5 years. He enjoyed the private lessons of Gassendi, who was combating Aristotle and Descartes, then the highest authorities in philosophy, and was associated with the prince of Conti, afterward his patron and friend, with Bernier, Hesnault, and Chapelle, all of whom became remarkable for their independence and philosophical humor. In 1642 he is said to have accompanied Louis XIII. on his journey to Narbonne, fulfilling his father's office, and to have witnessed on his way the execution of Cinq-Mars and De Thou. He soon after began to study law at Orleans, and was admitted an advocate in 1645; but his taste for the stage diverted him from the profession, and caused his return to Paris. The attractions of the actress Madeleine Béjart were reported also to have influenced his judgment. The example of Richelieu had created a general interest in the drama, and Poquelin became the head of a troupe of amateur comedians, which was soon transformed into a regular professional travelling company, known as *l'illustre théâtre*. He then assumed the name of Molière. Little is known of his life in the provinces, as strolling player, manager, and author, from 1646 to 1658, when he returned to Paris. He composed numerous slight pieces, imitations of Italian farces, some of which were the first sketches of his future comedies. At Bordeaux he was welcomed by the duke d'Épernon; at Lyons he obtained the accession of Mme. Duparc and Mme. De Brie to his company, which already included the brothers and sister Béjart; and at Pézenas there is still preserved the chair in which he was accustomed to sit every Saturday in a barber's shop to study the faces and conversation of the visitors, thus indicating the disposition for silent observation which increased with his years. His first regular comedy was *L'étourdi*, represented at Lyons in 1653, which is superior to those of Scarron and Scudéry that preceded it, and by its success induced the principal members of a rival company to join his troupe. He went thence to Béziers at the invitation of the prince of Conti, who was not yet a Jansenist, and who was so delighted

with *L'étourdi* and *Le dépit amoureux* that he vainly sought to engage Molière as his secretary to succeed the poet Sarrazin. At Avignon he was intimate with the painter Mignard. Having visited the principal cities of the south, he began to approach the capital, which he entered under the protection of Monsieur, duke of Orleans, in 1658. His first performance was the representation of Corneille's *Nicomède* and his own *Docteur amoureux* before the court and the comedians of the hôtel de Bourgogne, and was so satisfactory that his company was permitted to establish itself in Paris under the name of the *troupe de Monsieur*. It became the *troupe du roi* in 1665, and in 1680 was united with that of the hôtel de Bourgogne to form the *théâtre Français*. During the remaining 15 years of his life he produced more than 30 plays, half of which are masterpieces. He opened a new path in 1659 by his *Précieuses ridicules*, abandoning the traditions of the Italian and Spanish stage, and assailing the affectations encouraged in literature and society by coteries that ridiculously adopted the tone of the hôtel de Rambouillet. The price of admission was trebled on the second day, yet the play had a run of 4 months. The author was greeted from the pit by the cry of an old man: *Courage, Courage, Molière! voilà la vraie comédie*; a judgment confirmed by the public and by posterity. After witnessing its triumph, he declared that he no longer needed to study Plautus and Terence, but only the world. At brief intervals followed *Sganarelle, ou le cocu imaginaire* (1660), a somewhat scandalous farce; *Don Garcie de Navarre* (1661), which proved a failure; *L'école des maris* (1661), the leading idea of which is borrowed from the *Adelphi* of Terence, and in which the character of Sganarelle attains its fullest development; and *Les fâcheux* (1662), the first and one of the finest examples of a *comédie à tiroirs*, designed to be acted in the intervals of a ballet, and which was a principal attraction at Fouquet's famous and unlucky fête in the chateau of Vaux. In the same year occurred his marriage with Armande Béjart, a sister of the actress in his company, and whom the slanders of the time charged with being a daughter of his former mistress. The charge was however discredited by the king, who with Henrietta of England stood sponsors for his first child, and has been completely disproved by legal documents brought to light in 1821. His 3 next plays, *L'école des femmes* (1662), *La critique de l'école des femmes* (1663), and *L'impromptu de Versailles* (1663), successively increased the animosity against him, for which his own imprudence furnished the pretext. The first and second aroused the suspicions of the religious party, and gave rise to literary discussions like those which Corneille had caused by the *Cid* and Racine by the *Phèdre*; and the third drew upon him the unscrupulous assaults of the rival troupe at the hôtel de Bourgogne. All who had suffered by his satire or been eclipsed by his success combined to cir-

culate libels. Montfleuri, who may be said to have discharged the functions of liar-general, vainly tried to make himself heard at court. Unfortunately the host of indecent stories were embodied in an anonymous volume entitled *La fameuse comédienne, ou histoire de la Guerin* (Frankfort, 1688), which gained the attention of Bayle, whose dictionary has led many subsequent writers to repeat or to refer to them. In 1664, at the brilliant fêtes of Versailles Molière and his company contributed to the gayeties on 4 of the 7 days. He presented *La princesse d'Élide*, a romantic and gorgeous play, and the first 3 acts of *Tartufe*, a satire on hypocrites, which was deemed diverting at court, but the king forbade its representation in Paris. This ban stimulated public curiosity, and the piece was soon completed, and acted with great applause in Fontainebleau and other towns. The Jesuits and the Jansenists only made it more effective by each contending that the other was the real object of attack. Vexed at the prohibition which deprived him of the approval of a Parisian audience, he treated a kindred topic in the comedy of *Le festin de pierre* (1665), which portrays the multiple character of Don Juan at once as atheist, libertine, and hypocrite. This was preceded by *Le mariage forcé*, directed against the theologians of the Sorbonne, and followed by *L'amour médecin*, which began the war with the medical faculty that he continued through life. He was then in the period of his most productive and highest power. Within the next 3 years followed *Le misanthrope*, which Frenchmen pronounce the *chef d'œuvre*, partly from its faultlessness of style, and partly from its portrayals of Alceste, who runs counter to the conventional recognized, and therefore harmless hypocrisy of social intercourse, and of Celimène the coquette and Arsinoë the prude; *Le médecin malgré lui*, a rollicking farce, which had the greatest success; *Amphitryon*, an imitation of Plautus in reading which Voltaire confesses to have tumbled from his chair convulsed with laughter. *L'avare*, exhibiting in the character of Harpagon the comical relations of avarice; *Les Georges Dandin*, designed to expose the evils chief resulting from ill-assorted marriages, especially from the union of ruined aristocrats with wealthy *parvenus*. His *Tartufe* was also acted with signal applause at the Palais Royal, but its second representation was immediately forbidden, and within a week the archbishop had threatened excommunication against those who should act, read, or listen to it. It is the greatest effort of his genius, and those who take umbrage at it as bringing religion into ridicule have been advised to read it, since they are probably among those for whom benefit it was intended. In the 4 years between the performance of *Tartufe* in Paris and the death of Molière, the less important plays which he successively produced were the *Amant de Monsieur de Pourceaugnac*; the *Amant comique*; *Le bourgeois gentilhomme*; and *Le malin*, in which astrology is satirized:—

Fourberies de Scapin, containing the effective quotation: *Que diable alla-t-il faire dans cette galère? Psyché*; and *La comtesse d'Escarbagnas*. To this period belong two masterpieces, *Le bourgeois gentilhomme* (1670) and *Les femmes savantes* (1672), the former displaying the absurd conceit of plebeians in seeking the culture, manners, and acquaintance of the nobility, the latter aimed against pretenders to taste and science, who pride themselves upon what they neither possess nor understand. His dramatic career terminated with the *Malade imaginaire*. He had acted in its fourth representation, but his cough rendered the task difficult, and he returned to his chamber to die within an hour. Two sisters of charity, who had often experienced his hospitality, were by his side, but his eye vainly wandered to the door in hope of priestly consolation; and at first he was even refused burial in consecrated ground. "What!" said his widow, "refuse him sepulture! In Greece they would have raised altars to him." A multitude of anecdotes indicate the nobility and truthfulness of his nature, his scorn of every thing false, his unostentatious kindness and generosity. As an actor he attained high success by his tact and finesse, by dint of study and effort, despite physical disadvantages. He excelled in the most difficult parts, in those of Arnolphe, Orgon, and Harpagon, and in the original and typical characters of Mascarille and Sganarelle. Though the most inventive of comic poets, few writers have borrowed so freely from others. His imitations of Italian, Spanish, and Latin comedies are constant and undisguised, and are to be attributed to the occasional character of many of his pieces, written in the exigency of the moment at the command and for the entertainment of the court. The French maintain his superiority to all earlier and all later writers of comedy. La Harpe declares comedy and Molière synonymous terms; Chamfort calls him the most amiable teacher of humanity since Socrates, and believes that Julius Cæsar, who called Terence a half Menander, would have called Menander a half Molière; and even Hallam ventures to compare him only with Shakespeare, claiming that the latter had the greater genius, but admitting that the former wrote the better comedies. More than a century after his death (1778), the French academy, which had refused to receive him on account of his profession as comedian, decided to admit his bust into its chamber with the inscription proposed by Saurin: *Rien ne manque à sa gloire; il manquait à la nôtre.*—Among the best editions of Molière are those of Auger (9 vols., 1819-'25) and Aimé-Martin (8 vols., 1833-'6). The best biographies are by Taschereau (Paris, 1825; with supplement, 1827) and Barzin (1851).

MOLINA, Luis, a Spanish Jesuit, born at Valencia in 1585, died in Madrid, Oct. 12, 1600. He entered in early life the order of the Jesuits, and made his theological studies at Coimbra. Among his teachers was Peter Fonseca, who

inducted him into the doctrine of the *scientia media*, and who later, when the promulgation of this doctrine by his pupil began to agitate the theological world, confessed himself its author. Molina became later a distinguished professor of theology at Evora in Portugal, where he taught for 20 years. Among his works are: *De Justitia et Jure* (6 vols., Mentz, 1659); *Commentarii in Primum Partem D. Thomæ* (1593). But his principal work, which has immortalized his name in the annals of theology, is *Liberi Arbitrii cum Gratia Donis, Divina Præscientia, Providentia, Prædestinatione et Reprobatione Concordia* (Lisbon, 1588; an appendix, containing a defence of his doctrines, appeared the next year). The book came at once into general circulation, and editions of it were published at Lyons in 1593, at Venice in 1594, and at Antwerp in 1595. Molina affirms in it that the decree of predestination to eternal glory was founded upon a previous knowledge and consideration of the merits of the elect; that the grace from whose operations these merits are derived is not efficacious by its own intrinsic power only, but also by the consent of our own will, and because it is administered in those circumstances in which the Deity, by that branch of his knowledge which is called *scientia media*, foresees that it will be efficacious. By *scientia media* the theological schools understood that foreknowledge of future contingents that arises from an acquaintance with the nature and faculties of rational beings, of the circumstances in which they shall be placed, of the objects that shall be presented to them, and of the influence which their circumstances and objects must have on their actions. The doctrine of Molina was soon violently assailed, especially by the Dominicans, and it was even denounced to the inquisition at Valladolid. At length the controversy was brought before the pope, Clement VIII., who in 1597 appointed a congregation (*congregatio de auxiliis*) to investigate the matter. It was found that nearly the whole order of the Jesuits espoused the cause of their fellow member, while the Dominicans were just as unanimous in demanding the condemnation of his doctrines. The bishops who were consulted were divided in their opinions. The pope at length gave the decision, that both doctrines, that of Molina as well as that of his opponents, might be safely taught within the Roman Catholic church. A large majority of the Roman Catholic theologians have since declared against at least some of the points of Molina's system.—See Sotwel, *Bibliotheca Scriptorum Societatis Jesu*; Le Blanc (Dominican), *Historia Congregationis de Auxiliis* (Louvain, 1700), and on the other side, Theodorus Eleutherius (Jesuit), *Historia Controversiarum de Divina Gratia Auxiliis* (Antwerp, 1705); and Ranke, "History of the Popes," book vi. § 9 (London, 1853).

MOLINE, a village of Rock Island co., Ill., on the Mississippi river, and on the line of the Chicago and Rock Island railroad; pop. about

silurian to the present epoch; a species of *Lingula* has recently been discovered by Prof. Agassiz on the coast of South Carolina, the first on the American side of the Atlantic basin. *Lingulae* live near the surface, but some *terebratulæ* dwell beneath a pressure of 60 to 90 fathoms of water, explaining the strength and complexity of some parts of these minute animals. The brachiopods were most abundant and varied in geological ages, and are among the most ancient of existing types of animal structure, their range in space having been as extensive as their range in time. The brachiopods propagate by eggs, and, according to some, also by gemmation.—The last acephalous order is the *lamellibranchiata*, characterized by a right and left shell, enclosing a depressed body, covered on both sides by a layer of the mantle; the branchiæ are at the sides of the body, mostly lamellar (whence their name) and placed under each lobe of the mantle, but sometimes pectinated; they are generally two on each side, and sometimes the triangular interval between them on the dorsal surface is used as a temporary deposit for the eggs. Most have 4 lamelliform tentacles, in pairs on the sides of the mouth; the shells are opened by an elastic ligament at the back, and are closed by one or two internal muscles, in the former case being called *monomyaria*, and in the second *dimyaria*. The heart is arterial, consisting of a ventricle and usually of 2 auricles, the former being generally traversed by the end of the intestine. They inhabit both salt and fresh water, and usually live with the back uppermost, resting on the ventral edge of the shell; the sexes are in most cases distinct, and may often be recognized by the shape of the shell; some are hermaphrodite, and the young are sometimes considerably different from the adults; they are ovoviviparous. As a rule there are 8 central nerve masses, each consisting of 2 lateral ganglia, of which the first 2 are always distinct from each other. The valves of the shell are in most of the same shape and size, but in some of the fixed species the lower is the deeper; in the oyster the lower and larger is the left valve; in some the valves close tightly, in others they are open at one or both ends for the passage of the foot and other organs. Along a part or the whole of the margin of the mantle are conical cirri or organs of touch, and also tactile gill-like laminae around the mouth; and this class is frequently sensible of light. Some of this class, like the brachiopods, are fixed; others have a firm and muscular prolongation from the abdomen, called the "foot," possessing great contractility, by means of which they move about at the bottom of the water; at the base of the foot in some species is a bundle of thread-like filaments, called the *byssus*, secreted by a glandular tissue, and occasionally united into a common mass; a familiar example of this is seen in the common mussel (*mytilus borealis*, De Lam.), which attaches itself by its silken threads very firmly to rocks, shells, and sea weeds; a few, unprovided with a byssus, grow fast by one of

the shells to submarine objects. Many of the class are entirely fossil, and of some genera the extinct species are more numerous than those now living, the latter being in this case usually found in the Indian and S. Pacific oceans. Among the monomyarians may be mentioned the common oyster and the comb or scallop shell (*pecten*); among the dimyrians, the pearl oyster (*meleagrina*), hammer shell (*malus*), wing shell (*pinna*), mussel (*mytilus*), ark shell (*arca*), fresh water clam and mussel (*unio* and *anodonta*), cockle (*cardium*), the great clam or *bénitier* (used in Roman Catholic churches to contain holy water, sometimes 2 feet wide), genus *tridacna*, the largest of the class, the horse-foot clam (the beautiful *hippopus*), the edible quahang (*venus mercenaria*), the shell from which the wampum of the American Indians was made, the small fresh water cycla, the common clam (*mya arenaria*), the razor shell (*solen*), the *pholas* (piddock or stone-borer), the ship worm (*teredo*), so destructive to timber in vessels and dockyards, the waterpot shell (*aspergillum*), and the club shells (*clavagella*). All bivalves are very prolific; in those which like the oyster, are fixed, the sperm cells of the male are carried by the currents of the water to the cavity of the mantle of the female, as the pollen of the male tree is wafted by the air to the stigma of a distant female tree.—The remaining three fourths of mollusks are called *cephala*, from having a distinct head, commonly with eyes and tentacles, and a mouth with a complex masticatory apparatus; they have been divided into the class of *cephalophores* (head bearers) and *cephalopoda* (with the head surrounded by the feet). The *cephalophores* have been subdivided, according to the modifications of the locomotive organs, into the orders of *pteropoda*, *heteropoda*, and *gasteropoda*. The *pteropoda* are so called from 2 wing-like muscular expansions from the sides of the anterior part of the body, used as swimming organs and not, according to Owen, homologous with the foot of gasteropods; they are small, marine, floating, hermaphrodite, and oviparous; their form is very variable, some being globose, others long and slender; the heart, as in the whole class, is arterial, that is, receiving blood from the respiratory organs and giving off arteries to the body; the urinary sac, within the mantle and near the heart, communicates with the respiratory cavity and with the pericardial sinus, introducing water into the blood; some are naked, others are provided with very delicate shells of various forms; the eyes are generally well developed, but the acoustic sac exists in the naked species have 4 tentacles, the terebraceous ones only two. In the order *thamnota* the head is indistinct, and the shell fragile; the best known genera are *Hyalea* and *clavella*, found in the warmer temperate and tropical seas; some of them are beautiful objects as they swim through the water like butterflies in the air; one of the largest and finest is the *tridentata*, $\frac{1}{4}$ of an inch long, commonly known

poets have made to sail upon imaginary waters, propelled by 2 arms expanded to catch the breeze, and by the others used as oars; the scientific accuracy of this opinion will be discussed and fuller details given under NAUTILUS, though strictly speaking the argonaut belongs to a different order of cephalopoda. The shell is used only for protecting and hatching the eggs; the male has no shell, and impregnation is effected by a deciduous *hectocotylus*.—The local distribution of faunæ and the distinctness of zoological regions are well illustrated by mollusks; while some are very limited in their range, others, like the *cypræa*, are extensively spread even across ocean barriers; some are cosmopolite, wandering wherever their food is found; *helix cellaria*, attaching itself to water works, occurs in most seaports of the world, *H. imilaris* wherever the coffee plant grows, and *L. vitrinoides* follows the taro or *arum esculentum*. Local collections have an aspect peculiar to the region, and certain forms are eminently characteristic; analogous species are found in coördinate regions, more marked on the isothermal lines of longitude than of latitude; in the latter case we have analogous genera, but in the former not only the same genera, but closely allied if not identical species. As a general rule, according to Mr. Jeffreys "Annals and Magazine of Natural History," 2d series, vols. ii. and v., 1858-'60), specimens are larger toward the north than toward the south; colors are usually the brightest in the tropical seas, except in specimens from great depths. (For details on distribution, see "Mollusca and Shells of the U. S. Exploring Expedition," 1838-'42, by A. A. Gould, M.D., Boston, 1852.) The distribution of mollusks in time is also very interesting, extending as they do from the lower silurian to the present epoch, and affording precious materials for the geologist and palæontologist; all the classes are represented in the earliest fossiliferous strata; some families, like the ammonites and belemnites, have passed away; others, like the nautilus, are verging toward extinction; some, like the *ingula*, have continued with slight specific modifications from the silurian to the present day. On the whole, it may be said with Prof. Owen, that as far as we can see "through the dark vistas of geological time, we discern an ascent and progress in the main; lamelli-branchiate have superseded palliobranchiate bivalves; siphonate have succeeded asiphonate univalves; and the dibranchiate now vastly outnumber the tetrabranchiate cephalopods." Whole strata of the earth's crust are made up principally of the shells of mollusks.—Mollusks are useful to man in many ways; they supply an abundant, wholesome, and usually easily digestible article of food to nations civilized and savage; as for instance, oysters, clams, mussels, snails, and some cephalopoda, bivalves being considered the best, as having the least muscular fibre. In the arts, the ornamental purposes to which the pearl and cameo shells are put

are well known; from the cuttle fish is obtained sepia and India ink; from the *purpura* and *buccinum* of the Mediterranean came the famous Tyrian dye of antiquity; from the filaments of the byssus of *pinna* are made tissues much esteemed on the shores of the Mediterranean. On the other hand, mollusks are sometimes injurious to man; slugs and snails do mischief in gardens; the *teredo* pierces ship timber, and the *pholas* bores into and weakens stone dikes. Not only man but aquatic mammals, birds, reptiles, fishes, and many invertebrates find an ample supply of food in mollusks; and indeed they could hardly escape extinction, were it not for their great fecundity and the inaccessible places in which most of them dwell. The number of species of mollusks probably exceeds 25,000, surpassed only by the number of articulates. The collection of Mr. Hugh Cuming, of London, now (1860) contains about 20,000 species, and nearly 100,000 specimens, obtained from every part of the globe, and is altogether the finest in the world, not only in extent, but in perfection of the specimens; the collection is freely opened to students in this department.

MOLOCH, the national god of the Ammonites, who was worshipped by human sacrifices. The Hebrews seem to have been often addicted to his worship. Solomon, induced by his foreign wives, built a high-place to him; Manasseh imitated this impiety; and the idolatry continued from that time chiefly in the valley of Tophet and Hinnom, till the place was defiled by Josiah. Some of the rabbis explain the terms, which are generally thought to refer to the burning of children as sacrifices to this divinity, to mean only the passage between two fires, or the act of leaping over a fire, as a symbol of purification. Moloch is sometimes identified with the Phœnician Baal.

MOLOCH, an Australian iguanian reptile, of the family *agamidae*. The *M. horridus* (Gray) is the most ferocious-looking of any of the lizard tribe, and as ugly as any of the representations of fabled basilisks and dragons. The whole surface of the body is covered with irregular plates and strong sharp spines, and the upper surface of the head is crowned with two very large spines; on the back of the neck are large rounded protuberances, similarly armed with granular scales and spines. With all its spiny armature, it is an inoffensive creature.

MOLOSSIA, or Molossia, in ancient geography, a division of Epirus in N. Greece, extending across the province from N. to S. between Athamania on the E. and Thesprotia on the W. In early times it was peopled by various tribes of unknown race, with whom the Molossi, a Grecian people, who claimed descent from the Pyrrhus (Neoptolemus) of Homer, mingled in a later period. Though regarded as half barbarians, the Molossi became predominant in Epirus, and succeeded in establishing a royal dynasty over the whole country in the last quarter of the 4th century B. C., the capital being Ambracia (now Arta), on the gulf called after it.

MOLTKE, ADAM WILHELM VON, count, a Danish statesman, born Aug. 25, 1785. His family came originally from Mecklenburg. He was minister of finance under Christian VIII., and after the revolution of 1848 he became head of the administration, as well as finance minister. In November he became minister of foreign affairs, and continued at the same time his functions as premier until Jan. 27, 1852, when he withdrew from public life. He is known as using his great wealth for the promotion of science and art.—Another member of the same family, Count **ADAM GOTTLÖB DETLEV** (born 1765, died 1843), was devoted to the principles of the French revolution to such an extent, that he relinquished his title of count and signed himself Citoyen Moltke. His younger brother, Count **MAGNUS**, born Aug. 20, 1788, was a member and for some time president of the Schleswig provincial diet, where he became noted for his liberal political principles, which are further attested by his work "On the Nobility and on its Relations to the Bourgeoisie" (Hamburg, 1880), by the description of his travels in upper and central Italy (1881), and by other writings.—Count **KARL**, the eldest son of Count Adam, born Nov. 15, 1800, officiated as minister in Schleswig in 1852, was known for his sympathies with Russia and the absolutist party in Denmark, and died in 1858.

MOLUCCAS, or **SPICE ISLANDS**, a group of the great Indian or Asiatic archipelago, between lat. 2° N. and 9° S., and long. 122° and 131° E., and scattered over the sea which extends from the E. coast of Celebes to the W. coast of New Guinea; pop. about 600,000. The number of the islands is estimated at several hundreds; many of them, however, are small and uninhabited. The group is formed of 8 clusters, viz., the Gilolos or Moluccas proper, the Ceram, and the Timor Laut. The first of these comprehends the islands of Gilolo, Morty, Mandioly, Batchain, Ooly, Mysole, Ternate, Tidor, and many others of smaller size. The Ceram cluster, which lies in the centre of the group, contains, among others, the islands of Ceram, Booroo, Amboyna, and Banda. The third cluster lies further to the S. between Australia and the W. of New Guinea, and includes the Timor Laut, the Key, and Aroo islands. The outline of the coast of the Molucca islands is very irregular; in many places they rise abruptly from the water to a considerable elevation. There are many excellent harbors, but sand banks are frequently formed by earthquakes which render navigation intricate and dangerous. Nearly all the islands are mountainous, and some of them contain peaks which rise to a height of 7,000 or 8,000 feet. The formation of the group is volcanic; the surface is broken and indented in a singular manner, with enormous peaks and rocks piled up to immense elevations; there are several active craters and hot springs, and violent earthquakes are frequent. On account of the comparatively small size of the islands and the regular monsoons, the heat is never exces-

sive. Cereals cannot be cultivated to any great extent, and as a substitute for bread the people subsist almost entirely upon the pith of the sago palm. The most common tropical fruits and vegetables thrive well, and sugar cane, coffee, pepper, cotton, and small quantities of indigo are grown; but the Moluccas are especially remarkable for the production of cloves and nutmegs. The breadfruit tree, the cane, and all the fruit trees of India are found. There are over 400 different kinds of wood in the forests, including the *lingoa* (*protocarpus*), which is admirably adapted to cabinet work. No metals are found on the Molucca islands. The group has few indigenous animals; most of the domestic kinds have been introduced. The surrounding seas are exceedingly prolific, and the cachalot, which yields the spermaceti of commerce, is abundant and attracts many whale ships to the neighborhood. Pearls are frequently found on the coasts. Cloves and nutmegs are exported in large quantities; sandal and other valuable woods are obtained; and birds' nests, sea slugs, and shark fins are sent to China. The imports are chiefly opium and some Indian and European goods. The Dutch monopolies confined the commerce for many years within very narrow limits, but a more liberal policy has lately been adopted, and it is said to be improving.—The Moluccas include nearly all the islands which constitute the Indian archipelago, are inhabited by two races, the Malays and the Papuan or oriental negroes. The latter people, supposed to be of the same family as the aborigines of Australia and New Guinea, have in many of the smaller islands been exterminated by the Malays, and in the larger ones have only retained possession of the inferior and more inaccessible parts. The Malays of the group are very much mixed with Chinese and people of Arabian descent. They are in possession of the lower lands and sea coasts, where they cultivate the ground or gain subsistence by fishing. In disposition they are wild and ferocious. They are very expert in the construction and management of their vessels. The Malay is the common language; the Arabic character is employed in writing. Mohammedanism, mixed with some Hindu rites, is the prevailing religion; but some profess Christianity, and distinguish themselves by wearing black garments. The laws are chiefly founded upon the precepts included in the Koran.—Like other portions of the Indian archipelago, the Moluccas had been visited by the Arabs, and the Mohammedan religion spread among the people long before the arrival of the Portuguese in 1510, by way of the Cape of Good Hope, and of the Spaniards by way of Cape Horn shortly afterward. The Portuguese had only begun to form settlements when the Spanish vessels, under Magalhaens, arrived from the east, and a prolonged dispute arose between the two nations respecting the possession of the islands, which terminated in favor of the Portuguese. A system of violence and oppression

tion was maintained for 60 years, when the Dutch with the assistance of the natives expelled the Portuguese. The Dutch East India company, formed in 1602, had obtained in 1618 the supremacy over many of the native princes, and allowed them to retain their authority by paying tribute to the company. In order to secure to themselves the exclusive trade in nutmegs and cloves, the Dutch formed numerous small settlements throughout the group, by which means they kept the petty sovereigns in subjection, and with their assistance were enabled to extirpate the spice trees on all the islands except Amboyna and Banda, which two they reduced entirely under their authority. With the view of keeping up prices in foreign markets, the Dutch frequently burned whole cargoes of spices. The English were allowed at one time to have a mercantile establishment at Amboyna, when held by the Dutch; but the latter in 1623, after forcing some Chinese and Javanese soldiers by torture to make confession of a plot on the part of the English, seized on the leaders and put them to death with circumstances of the most horrible cruelty. In 1796 the British took possession of the Moluccas, and kept them until the peace of Amiens (1802), when they were restored to the Dutch. The British again took possession of them in 1810, and again gave them up to Holland by the treaty of Paris in 1814. In 1824 some of the more oppressive laws were repealed, and the free cultivation of the islands allowed. The seat of the Dutch governor-general is at Amboyna.

MOLYBDENUM, a white brittle metal, extremely difficult of fusion, first separated from its peroxide, molybdic acid (MoO_3) by Hjelm in 1782; symbol, Mo; equivalent, 46; specific gravity, 8.615 to 8.636. Scheele in 1778 first distinguished its ore, the bisulphuret, from graphite, with which it had been previously confounded, and obtained from it molybdic acid. This may be done by roasting the sulphuret. The product is reduced to the metallic state by exposing a mixture of it with oil and charcoal in a brasqued crucible to intense heat. It may also be reduced when exposed at high temperature in a porcelain tube to a current of hydrogen. In the pulverulent state it soon absorbs oxygen and loses its metallic character, and masses of the metal when heated undergo the same change. Molybdic acid is found in nature combined with lead in the yellow ore, molybdate of lead.—Sulphuret of molybdenum, MoS_2 , is a bluish lead-gray mineral, of hardness 1 to 1.5, specific gravity 4.55 to 4.65, consisting of sulphur 40 and molybdenum 60 per cent. It occurs in small laminated masses, or in small regular hexagonal tables, which cleave in planes parallel to the base of the crystal. It marks paper like graphite; upon porcelain its traces appear greenish. It occurs in granitic and other crystalline rocks, and, disseminated in small quantities, is not rare. It is obtained to small extent for chemical purposes, and for preparing blue dye, and is worth about \$8 per lb.

MOLYNEUX, WILLIAM, an Irish mathematician, born in Dublin, April 17, 1656, died there, Oct. 11, 1698. After graduating at Trinity college, he went to London, and entered the Middle Temple as a law student. He afterward on returning to Ireland applied himself to the study of mathematics. In 1683 he aided in forming the Dublin philosophical society, whose president he ultimately became. In 1685 the English government commissioned him to inspect the fortresses in Flanders. In 1688 the severities of Tyrconnell's administration compelled him to seek refuge in England; but after the revolution he repaired again to Ireland, and was chosen a member of the Irish parliament for Dublin. Among his correspondents were Newton, Locke, and other eminent men. His principal work is a treatise on optics (*Dioptrica Nova*, 4to., London, 1692 and 1709).

MOMBACHO, a principal volcano of Nicaragua, on the S. shore of Lake Nicaragua, a few miles from the city of Granada. It has an elevation of 4,600 feet, a broad base, and a wide and ragged crater, within which is a lake of water. The lake at its base is studded with conical, volcanic islets, many hundreds in number. The country around it bears marked traces of violent volcanic action of ancient date.

MOMBAS, **MOMBAZ**, or **MOMBASAH**, a town on a small island of the same name, in a bay on the coast of Zanzibar, lat. $4^\circ 4'$ S., long. $39^\circ 38'$ E.; pop. 4,000. The island is about 8 m. long and 2 m. wide; and the coasts consist of steep cliffs which render the town almost impregnable, while it is further defended by an old Portuguese fort. The town is in a ruinous condition, and is inhabited by Arabs and people of mixed race. The bay in which the island is situated is about 5 m. long and 3 broad, and forms the harbor of Mombas, said to be unsurpassed. There is very little trade, and the people are exceedingly poor. The Portuguese destroyed the native town in 1505, and again in 1529; from which time they held the place till they were driven out by the imam of Muscat in 1720. In his turn he was expelled by the natives, who hoisted the English flag, and from 1824 to 1826 the town was under the protection of the British; but they refusing to retain it, the flag was struck, when Mombas fell again into the hands of Sultan Seid Said, who received material assistance in its recovery from an American adventurer with a heavily armed ship. The London church missionary society established a mission at Mombas in 1844, chiefly with the view of having a convenient station as a centre from which to spread the gospel among the tribes of E. Africa.

MOMMSEN, THEODOR, a German historian, philologist, and jurist, born in Garden, Schleswig, Nov. 30, 1817. He studied at the gymnasium of Altona and the university of Kiel. His proficiency in classical philology, and particularly in that branch of it which the Germans call *Epigraphie*, and which has for its object the investigation of inscriptions on public mon-

uments and of other records of antiquity, gained him pecuniary assistance from the Berlin academy in his explorations in France and Italy, (1844-'7). In 1848 he was attached to the staff of the *Schleswig-Holstein'sche Zeitung*, a political journal. His participation in the movements of 1848-'9 caused him to be removed in 1850 from the chair of jurisprudence at the university of Leipzig, which he had filled for some two years. From 1852 to 1854 he was professor at Zürich, and from that time till the present (1860) at Breslau. His lectures on Roman law have given him a high rank among jurists, while his researches in classical archaeology and philology have placed him by the side of Böckh, K. O. Müller, and other distinguished German scholars in that department. His *Oskische Studien* (Berlin, 1845; supplement, 1846), *Die Unteritalienischen Dialekte* (Leipzig, 1850), and *Corpus Inscriptionum Neapolitanarum* (1851), have opened a new era in the study of the philology and archaeology of S. Italy, particularly the last work, which contains one of the largest and most remarkable collection of Roman inscriptions extant. He has prepared a similar collection of the ancient inscriptions in Switzerland (Zürich, 1854). Among his other works relating to Rome, that on Roman currency (*Ueber das Römische Münzwesen*, Leipzig, 1850) is held in high esteem, as is that on the municipal institutions of Salpensa and Malaga (*Die Stadtrechte der Lateinischen Gemeinden Salpensa und Malaga*, Leipzig, 1855). His "History of Rome" is still in progress; the first two volumes appeared in 1854, and a second edition at Berlin in 1857. The 3d volume appeared in 1857.—His brother JOHANNES TYCHO, born in 1819, has published an admirable metrical translation of Pindar (Leipzig, 1846), and scholarly essays on that poet (1845) and on Shakespeare (1855).

MOMOTOMBO, the loftiest volcano in the republic of Nicaragua, 7,200 feet high, standing at the head of Lake Managua, 25 m. N. E. from the city of Leon. It is still what the Spaniards call *vivo*, or alive; that is to say, it sends out constantly a light plume of smoke, and occasional showers of fine ashes. The superior 8,000 feet of its elevation seems to be made up of ashes and scorise. It has never been ascended, and tradition reports that the early priests who undertook to plant the cross on its summits were never afterward heard of. This tradition has been made the subject of a poem in *La légende des siècles*, by Victor Hugo. There are various hot springs at the base of the volcano, and a number of orifices or vents (*infernillos*) on its flanks. It is a prominent landmark from the sea, and constitutes one extremity of the volcanic range of the Marabios, which terminates in the high cone of El Viejo.

MOMUS, in Greek mythology, the god of mockery and censure, said to have been a son of Nox. Having been chosen by Neptune, Minerva, and Vulcan to decide on the merits of their respective works, he censured them all, in

consequence of which he was expelled from heaven. He is generally represented raising a mask from his face, and holding a small map in his hand.

MONACHISM (Gr. *μονος*, alone), a term denoting solitary life or retirement from the ordinary concerns of the world, with a view to a more or less entire occupation of the soul with religious objects. Monachism had been in existence when Christianity made its appearance, but its greatest prosperity and development took place in the Christian church, and it is to Christian monachism that this article will be exclusively devoted. It is generally agreed that the germs of it can be traced to the earliest period of the church. Some Protestant historians have been of opinion that monachism was originally foreign to primitive Christianity, and that it was transplanted from non-Christian religions into Christian soil; but we oppose this view, and regard monachism as a natural and almost necessary phase in the progress of Christianity. In the 2d century we find some ascetics, who lived in celibacy and voluntary poverty and shunned intercourse with the world; but they remained isolated. Monachism was characterized as a denomination by some of those peculiar features which distinguished it without interrupting the communion of the monks with the world, both clergy and laity. At the end of the 3d and the beginning of the 4th century monachism received through Paul of Thebes, Pachomius, Anthony, and other saints, a definite shape, and spread throughout the eastern church with amazing rapidity. From its beginning it divided itself into two great branches, the ascetic, who regarded a complete isolation from their fellow men as the best means for a closer union of the soul with the Deity, and the contemplative, who preferred to organize themselves into ascetic congregations, and to aim at exhibiting the world, in the convent, the model of a sanctified community. Anthony was the father of the former, Pachomius of the latter class. The second form soon prevailed, though the first has not altogether disappeared up to the present day. After the first settlements of Pachomius on the island of Tabenna (340), of Basil in the Egyptian desert, of Hilarius in Gaza, of Ammonius in the Nitrian desert, of Eustathius of Sebaste in Armenia, the East, Asia Minor, Palestine, and Syria abounded with convents. The number of monks after the middle of the 4th century increased to many thousands. A part of them was devoted to mechanical trades, among which we find ship building, and to agriculture; all their occupations and rules were directed to overcome the desires of the body, and to make it a willing servant and instrument of the soul in its religious aspirations. A complete abolition of individualism was aimed at, in order that man should be wholly possessed and owned by God. It was to guard man against attachment to

fellow men, poverty against attachment to earthly possessions, unconditional obedience to superiors against attachment to himself. The new phenomenon soon secured the entire confidence of the church. The greatest teachers of the church, as Gregory Nazianzen, Basil the Great, and Chrysostom, were its enthusiastic admirers and promoters. From the desert, monastic institutions were soon transplanted to the towns, where in agitated times they came to be regarded as safe places of refuge from the troubles of the world. The writers of the church soon had to lament that many fled to the convent only for the purpose of finding there an easy and comfortable life; that the mask of piety served frequently for concealing laziness and wickedness; that excessive and ill-directed asceticism led many to despair, suicide, licentiousness, and insanity; that gross ignorance and wild fanaticism made the monks the most dangerous tools in the hands of ambitious men, and that their zeal could be turned to acts of violence against Chrysostom as well as to the destruction of pagan temples or the suppression of Arianism. The emperor Valens and several of his successors sought, but in vain, to arrest the too rapid increase of monachism. The contemplative life led many astray into gross anthropomorphism, which caused their exclusion from the church. But though many censured the abuses of monachism, but few were found, like Jovinian, to assail the principle. The abandonment of the monastic state was regarded as a weakness, but in the earlier centuries was not forbidden, although the seceder had to take upon himself a public penance. Beside the more numerous cenobites, anchorites continued to exist, and often received recruits from the convents. They practised all sorts of self-torment, and tried to excel each other in rigor. The stylites, who were found until the 12th century, were the most celebrated among them. Under the growing influence of the Byzantine emperors, the eastern church, and with it eastern monachism, lost all vitality and became petrified. No attempts were made to revive its declining vigor by creating new organizations; traditionally all the eastern monks have followed up to the present day the so called rule of St. Basil, and have called themselves after either St. Basil or St. Anthony. They remain numerous in all the eastern churches, and some of their establishments, as the convents of Mount Athos, are still celebrated for their literary treasures or political influence; but they have ceased altogether to be powerful agencies of religious influence.—The West became acquainted with monachism through Athanasius the Great, who in 340, during his second exile, came to Rome in the company of some Egyptian monks. He soon prevailed on some men and women to embrace the monastic life, which was later particularly recommended by Ambrose, Jerome, and Augustine, and, in consequence of such patronage, soon struck deep roots. In Gaul it was introduced, before the close of

the 4th century, by Martin of Tours and Cassian, the latter of whom, by his work "On Monastic Institutions," awakened a desire for a perfection of the monastic constitution, and fixed certain hours for common religious exercise. In the West as well as in the East most of the monks were laymen, and only the abbot was a priest. The convents were dependent on the bishops, but exemption from episcopal jurisdiction began in Africa as early as the 6th century, and in Gaul in the 7th. It soon became customary to ordain monks to the priesthood, and after the close of the 4th century convents were commonly regarded as the nurseries of the clergy. Cassian, and after him Cassiodorus, recommended as a most suitable occupation for the working hours of the monks the copying of the classic authors and teaching, both of which became favorite occupations, the one remaining so until the invention of the art of printing, the other up to the present day.—A new epoch in the history of western monachism begins with Benedict of Nursia, whose rule (529) came gradually into general use, transforming the previously independent communities into a hierarchical religious order. Convents soon received a special importance as missionary schools, particularly in Ireland, whence a number of devoted monks went forth to complete the conversion of Germany and Switzerland. In these, as well as later in the Slavic countries, it was not only by preaching, but still more by the establishment of convents bearing the character of agricultural colonies, that the conversion of those pagan countries was advanced. The form which monachism took met so fully the approbation of the church, that attempts were made to subject all the secular clergy to similar regulations. This movement was inaugurated by Chrodegangus of Metz, who established the canons regular, but, though often renewed, could never be fully carried out. The rule of Benedict became the bond of union for most of the western convents; but the many favors received from church, state, and individuals, facilitated the growth of moral corruption to a much greater degree than in the eastern churches. The consciousness of this evil called forth attempts at reform, and for many centuries the history of monachism presents a continued struggle of reformers with the laxity, indifference, or immorality obtaining in a larger or lesser number of the convents of their times. The first of these reformers was Benedict of Aniane (died 821), whose commentary on the rule of Benedict of Nursia obtained later an equally authoritative character. Benno, who became in 910 abbot of Oluny, laid the foundation of the celebrated congregation of Oluny, a main pillar of the reformatory party, which was exempted by the pope from episcopal jurisdiction, and received the right of choosing an abbot with the dignity and authority of a bishop. Romoald founded the congregation of Camaldoli in 1028, Gualbert that of Vallombrosa in 1036. The Cistercians owed to their leader, St. Bernard, so great a celebrity, that

they were within a short time introduced into nearly all the European countries. The order of Grammont sought to excel all others in ascetical rigor, and that of the Carthusians adhered more faithfully than any other order to its original spirit. Other orders arose for special benevolent or religious purposes. The order of St. Anthony (1095) and the Hospitallers (1078) devoted themselves to the nursing of the sick, the order of Fontévrard (1094) to the correction of lewd women, and the Trinitarians (1198) to the redeeming of Christian prisoners. Even the warlike tendencies of those times sought a union with the monastic spirit by the establishment of several orders of knights, such as the knights of St. John, the templars, the Teutonic knights, the orders of St. Jago, Calatrava, Alcantara, Avis, and St. Maurice. The large increase of the number of orders called forth much opposition, and the council of Lateran in 1215 passed a resolution that no new order should be established. But notwithstanding this prohibition, the same period witnessed the birth of an entirely new class of orders, the mendicants (Franciscans, Dominicans, Carmelites, Augustinians, and several others), who inaugurated a new era in the history of western monachism. The dangers to which the church was exposed on the part of a number of new dissenting ecclesiastical bodies, required a more active and zealous agency, especially among the lower classes, than the older orders and secular clergy could afford. The mendicants tried to supply this want, and thus became more closely identified with and beloved by the people than any of the former orders had been. The rapidity of their success was astonishing, and very considerable privileges were conferred on them by the popes, frequently to the great annoyance of the bishops. They aimed at being the best soldiers of the church militant, and they had therefore a marked influence on subsequent church history. The Franciscans and Dominicans soon took the lead. Both created for themselves a numerous and influential party among the laity by the establishment of tertiarians, who bound themselves to the ascetic and devotional regulations of the order, without assuming its garb or entering the convent. Both secured also a number of chairs at the theological schools, in spite of the opposition of the secular clergy; and the most illustrious representatives of this and the following centuries (Thomas Aquinas, Bonaventura, Albertus Magnus, Alexander of Hales, &c.) were either Dominicans or Franciscans. Several of their members filled the highest ecclesiastical positions, even the papal chair. They raised monachism to the zenith of its power, influence, and prosperity. In the 14th century, though partly checked by the mendicant orders, a general degeneracy of monachism commenced, and the corruption from which hardly a single order kept itself entirely free became so overwhelming, that toward the close of the middle ages the name monk was often used by writers as synonymous with rudeness and ignorance.

Reformatory attempts were made in every century; a number of new orders, as the Jesuates, Brigittina, Servites, Hieronymites, and others, were founded; but their influence was weak in comparison with that of their predecessors, and frequently after an existence of 50 or 100 years they themselves departed from their primitive standard of rigid asceticism. The councils of Basel and Constance devised for a reformation of monasticism some highly important measures, which, however, could be carried out in a few places only. The Beguards or Beguins, who must be regarded as an offshoot of monachism, exhibited a freer and less hierarchical spirit; and their associational principle was further developed by the Brethren of the Free Spirit, who for some time seemed to be preparing the way for an entirely new phase of monachism, and in their reformatory labor came frequently in collision with the highest church authorities.—The reformation of the 16th century constitutes a new turning point in the history of monachism. The best and most influential men in the church cordially joined in the demand for a thorough reformation; they admitted that the crisis had been in part occasioned by the corruption of the clergy, secular as well as monastic, and they urged in particular the imperious necessity of a reformation of the religious orders. The reformers within the orders received therefore more energetic aid from bishops, popes, and councils. The internal history of nearly every order records, at this point of time, strong resolutions in favor of an enforcement of the rigorous primitive rules. In the most numerous and powerful orders, the Franciscans, in particular, the more rigorous party achieved a complete and permanent success over those inclined toward laxity, and several new reformed congregations branched off from them, among which the Capuchins were the most prominent. The council of Trent emphatically declared the usefulness of monastic establishments, and published a number of decrees which regulated their possessions, internal administration, and the election of superiors, provided for annual assemblies, and extended the rights of the bishops with regard to the inspection and superintendence of the convents. Beside the reformation of the old orders, the church showed herself most prolific in producing new ones. The character of the times expressed itself on most of the new societies. The monastic institutions of former days had been, as religious communities, essentially contemplative; the new ones were predominantly operative, the mendicant orders forming, so to speak, a connecting link between the two. Preaching, teaching, visiting the sick and poor, and similar objects formed the chief occupations of the new orders, to which their greatest energy was directed. The best known among the new orders are the Theatines, the Barnabites, the Oratorians, the Lazarists, and especially the Jesuits, and among the female orders the Elizabethines, Ursulines, and sisters of charity. The consti-

ion of the Jesuits was controlled, more than that of any other order before or after, by the principle of an absolute submission to the church and the pope. The order was to be an instrument in the hands of the church; the individual therefore was advised to become, with regard to the commands of his superior, as destitute of self-will "as a corpse," or "as a cane in the hands of an old man." No order ever carried out its fundamental principle more faithfully, and in all subsequent battles of the Roman Catholic church the Jesuits stood in the front rank. The culture of literature, against which in the middle ages some founders of monastic orders had expressly warned their members, showed itself, after the 16th century, so great a necessity, that it was practically observed by all orders, though but few gave it special attention. Among these few the French Oratorians and the Benedictine congregation of St. Maur hold by universal consent a prominent place among the great literary societies of the world. A more general attention was given by the religious orders to the cause of education, especially to primary instruction. Many congregations, both male and female, were instituted for this sole purpose, especially in France, and a large number of primary schools have ever since been under their direction.—The great losses of territory and membership which the Roman Catholic church suffered in consequence of the reformation, directed the attention of the monastic orders more than before to the foreign missionary cause. Most of the larger orders, especially the mendicants and the Jesuits, engaged in it with great zeal and emulation. The Jesuits took, in addition to the three common monastic vows, a fourth, binding them to go without hesitation as missionaries to any country where it might please the pope to send them. The extent of their missionary operations in Europe, Asia, Africa, and America, excelled any thing the Roman Catholic church had done in this field before. (See *MISSIONS*.) The great majority of the Roman Catholic missions in all pagan countries have ever since been conducted by the members of religious orders.—In the 18th century the productivity of the church, as regards monachism, greatly decreased; only the larger order, the Redemptorists or the congregation of the Most Holy Redeemer, founded by St. Alfonso di Liguori, sprang up during this time. Most of the orders, in the second half of this century, relapsed into either torpor or corruption, and made but a feeble resistance when the rationalistic views which became so prevalent among the educated classes in every European country, Catholic as well as Protestant, declared against them a war of destruction. Joseph II. suppressed as useless all convents of monks not occupied in education, pastoral duties, or the nursing of the sick; and many Catholic writers demanded the entire extirpation of monachism as both an outgrowth and a promoter of fanaticism. The pope yielded to the general pressure and abolished the most

powerful of all orders, the Jesuits. The French revolution soon afterward endangered the existence of monachism in most of the European states, but with the downfall of the Napoleonic rule its prospects began to brighten. Pius VII. in 1814 restored the Jesuits, who rose again to considerable strength and influence, wherever they were not forcibly suppressed. (See *JESUITS*.) In the countries of the Latin race, both in Europe and America, the fate of monachism was closely allied with the political strife of the conservative and the liberal or progressive parties, the former patronizing it together with all other ecclesiastical institutions, the latter subjecting it to prohibitive rules or suppressing it altogether. In consequence of the successes of the liberals, monachism was greatly reduced in South America, and in Italy (in 1848, and again in 1859 and 1860), and almost entirely suppressed in Portugal (1834) and Spain (1835). In France alone the vicissitudes of political rule in no way affected the rapid growth of monastic institutions, which, in point of zeal, activity, and general prosperity, were not behind what they had been during the golden era of their existence. Under the Bourbons and under Louis Philippe the liberal party occasionally demanded coercive measures against them; but since the establishment of the republic in 1848 even the liberals have given a wider interpretation to religious liberty, and accustomed themselves no longer to refuse the free right of association to the members of religious orders. Nearly every one of the old orders reestablished itself in France, and as a number of new congregations were formed, there is at present a greater variety of monastic institutions in that country than any state has possessed at any previous period. M. Dupin stated, in a speech before the French senate in July, 1860, that there were 4,982 authorized and 2,870 unauthorized establishments. Next to France, they are most numerous, wealthy, and influential in Belgium, where, as in France, public instruction is to a great extent under their control. Among the Germanic nations they partook, throughout the British possessions, North America, and Holland, of the blessing of truly liberal institutions, and peaceably lived in accordance with their rules, from which public opinion demanded only one departure, that no member wishing to leave their establishments should be restrained from doing so. Austria protected them, but kept them until 1848 under a bureaucratic guardianship, which has since been changed into a zealous support and encouragement. The revolution of 1848 procured them freedom in many other German states where before they had been either suppressed or tolerated under great restrictions; and even those states whose codes retain laws against their admission in general, as Sweden, Denmark, and Saxony, admitted the sisters of charity. In Russia they suffered severe losses, but Turkey became a prominent field for their missionary operations.—The number of monastic associa-

tions founded since the beginning of the 19th century is considerable, and exceeds the number founded during any other period of equal length. Most of them belong to France, and several have already attained a considerable extension. A peculiar feature which characterizes them as the offspring of the present age, and distinguishes them from all the preceding orders, is easily discerned in all of them; the marks which externally distinguish them from the non-monastic world are less visible, and the social wants of ecclesiastical and civil society stand preëminently forth as the primary cause of their origin and the chief object of their labors. A large number of them are devoted to the instruction of youth. Such are several congregations of school brothers and school sisters, brothers and sisters of St. Joseph, brothers and daughters of the holy cross, &c. Many others bind themselves to the service of the sick and the poor, as the little sisters of the poor, the most numerous and popular among them. Not a few cultivate the mission field; either the foreign missions, as the Picpus society, the Oblates, the brothers and the daughters of Zion (both for the conversion of Israelites, the latter consisting exclusively of converts); or the home missions, as the Paulists, established in 1858 at New York. In a literary point of view they are at present far from sharing the reputation of their predecessors in former centuries, though men like Lacordaire, Ravignan, and Gratry in France, Rosmini and Secchi in Italy, and Haneberg in Germany, occupy a high place in the annals of contemporaneous literature. In respect to their moral condition, Roman Catholics admit the existence in some places, particularly in Central and South America, of considerable corruption and ignorance in many convents of the older orders. In some of these also the ancient constitutions have fallen more or less into disuse. The regular connection of the general superiors with their subordinates has been in great part interrupted, and the holding of general assemblies has ceased. Pope Pius IX., at the beginning of his pontificate, proclaimed it as one of his chief tasks to carry out a thorough reform of monastic orders; and in some orders, as the Dominicans, an extensive reformation has since taken place. The number of monastic institutions in 1860 was estimated as follows: male orders and congregations 83, with about 7,065 establishments and 100,000 members; female orders and congregations 94, with 9,247 houses and a little more than 100,000 members. —The reformation of the 16th century rejected the monachism of the Roman Catholic and the eastern episcopal churches, as being based on the false principle of the meritoriousness of good works. One small denomination, the Dunkers, has retained nearly the whole of the monastic organization. In the church of England and the Protestant Episcopal church in the United States, sisterhoods have been formed at various times, and have of late increased in number under the auspices of what is common-

ly called the high church party. Solitary voices among the Protestant theologians of the 16th, 17th, and 18th centuries have expressed a regret that, with the monachism of the old churches, the principle of forming religious communities of men and women for the more efficient fulfilment of the duties of charity had been altogether discarded. Since the beginning of the 19th century both the "Evangelical" and the "High Lutheran" schools of Germany have approved the establishment of houses of deacons and deaconesses, also called brother houses and sister houses, the inmates of which associate for the purpose of teaching, of attending the sick, of taking charge of public prisons and for other works of Christian charity. Institutions of this kind are rapidly spreading in Germany and the adjacent countries. —The most important works on the history of monachism in general are: Hospiniani, *De Monachis libri II.* (Zürich, 1588, 1609); Helyot, *Histoire des ordres monastiques* (Paris, 1714-'19; new ed., with an additional vol. on the modern history of monachism, by Migne, 4 vols., 1849); and Döring, *Geschichte der Möncheorden* (2 vols., Dresden, 1822). A superior work was expected from Mühlert; he died after having barely commenced it; an interesting fragment is contained in his *Vermischte Schriften*, vol. ii. (Ratisbon, 1839). The most comprehensive work on the subject is Martene's *Les moines d'Occident*, the first two volumes of which were published in 1641 at Paris, and republished in English at Edinburgh and in German at Ratisbon. Another extensive work has been for some years in preparation by Dom Gueranger, the superior of the French congregation of Benedictines. The monastic statistics of the several countries may be found in Schem's "Ecclesiastical Year Book" for 1861 (New York, 1860). (See RELIGIOUS ORDERS.)

MONACO, a small principality of Italy, bounded S. by the Mediterranean, and surrounded on all other sides by the province of Nice, between the cities of Nice and Ventimiglia, extending 5 m. along the coast and about 3 m. inland, and consisting of the 3 communes of Monaco, Mentone, and Roccabruna; pop. about 7,000. The principal products are fruit and wine. The Genoese family Grimaldi was in possession of this territory under the protectorate of various governments from the 10th century until the early part of the 18th, when, by the marriage of the sole heiress of the name, it passed into the hands of Jacques de Goyon-Matignon, count of Thoiry. Under his grandson Honoratus it was united with the French republic in 1793, but restored to him in 1814, and ceded to Sardinia in 1815. The latter government acknowledged the independence of the principality, reserving to itself only the power of garrisoning it and of appointing the military commander of the town of Monaco. Honoratus V. succeeded his father in 1819, and died in 1841. His successor Florestan I. protested in vain in 1846 against the annexation of the communes of Mentone and Roccabruna by Sardinia, and

ed negotiations with foreign governments for the sale of his rights. He died in Paris, June 20, 1856, and was succeeded by his son under the name of Charles III., but his government in the principality was terminated by the events of 1859, which placed the whole territory under the control of Sardinia. Monaco, the capital, pop. about 2,000, is said to have become a rival of Nice as a watering place.

MONADNOCK, GRAND, a mountain in New Hampshire, near the S. W. corner of the state. The base covers an area of 5 m. by 8, and the altitude, according to Professor Dana in 1816, is 3,450 feet above the level of the sea. Several minerals are found on and around the mountain, and it contains talc, mica, and slate, distinctly stratified. It is visible from the dome of the state house at Boston, and is a conspicuous landmark for mariners approaching the coast. Seen from a distance, its summit appears of a rounded form, free from rocks and mural precipices. Many streams of water issue from Grand Monadnock, and from its top may be seen no fewer than 30 collections of fresh water, some of them large enough to contain islands of 8 or 10 acres.

MONAGHAN, an inland county of Ireland, province of Ulster, surrounded by Tyrone, Armagh, Louth, Meath, Cavan, and Fermanagh; area, 500 sq. m.; pop. in 1851, 141,758. The surface is in general hilly, except in the S. E., which is level, and forms the northern limit of the great central plain of Ireland. The principal mountains are the Slieve Beagh range, whose highest summit is 1,254 feet above the sea. The chief rivers are the Blackwater, Fane, Glyde, and Finn. There are several lakes, the largest being Muckno, or Barrac Lough, which is about 3 m. long and 1 m. broad. The soil is moory and peaty in the elevated districts, but fertile in the central and southern. The staple manufactures are linen, woollen, and earthenware. The minerals are iron, lead, coal, slate, marble, and building stone. Monaghan is divided into 5 baronies and 21 parishes, and returns 2 members to the imperial parliament. The chief towns are Monaghan, the capital, Clones, Castle Blayney, and Carrickmacross. It is traversed by the Ulster canal and various lines of railway.

MONASTERY, a house for the habitation of monks or nuns. When governed by an abbot or abbess, it is called an abbey; and when ruled by a prior or prioress, a priory. If the superior bears neither of these titles, it is generally known simply as a monastery, convent, or nunnery. The origin of monasteries may be traced to about the 3d century A. D., when the anchorites who inhabited the desert of Egypt began to build their cells adjoining one another, for the greater convenience of receiving the instructions of some hermit who enjoyed a reputation for peculiar sanctity. In the middle ages in Europe the monastery became almost a town in itself. Within it often could be found all the necessaries of life, many if not most of

which were the produce of the brethren's labor. Such were the famous convents of St. Gal, Fulda, Cluny, Cîteaux, and Clairvaux; and some of the Trappist monasteries retain much of the same character even to the present day. (See **MONACHISM**.)

MONBODDO, JAMES BURNET, lord, a Scottish judge, born at the family seat of Monboddoo, in Kincardineshire, in 1714, died in Edinburgh, May 26, 1799. He was graduated at the university of Aberdeen, and was sent to Groningen to study law. In 1788 he returned to Scotland, and practised at the bar till 1767, when he was made a judge. Boswell in his "Tour to the Hebrides" gives an account of a visit paid to him by Dr. Johnson, whom he resembled so much in some respects, that Foote the actor called him an Elzevir edition of Johnson. He was noted for his hospitality, and the guests at his learned suppers, as they were called, comprised the most eminent men of Edinburgh. He expressed an extravagant predilection for the language, literature, and philosophy of Greece, but at the same time held that the savage state was the happiest. He maintained that men were originally no better and possessed of no higher faculties than beasts, and that the orang outang is of the human species. His principal works are: "A Dissertation on the Origin and Progress of Language" (6 vols. 8vo., 1774-'92), and "Ancient Metaphysics" (6 vols. 4to., 1778).

MONCALVO. See **CACCIA**, GUGLIELMO.

MONCEAU. See **DUHAMEL DU MONCEAU**.

MONOREIFF WELLWOOD, SIR HENRY, a Scottish divine, born at Blackford, Perthshire, Feb. 6, 1750, died in Edinburgh, June 14, 1827. He was the son of the Rev. Sir William Moncreiff, and assumed the name of Wellwood in the latter part of his life. He was educated at Glasgow and Edinburgh, was ordained in 1771, and succeeded his father as minister in Blackford until 1775, when he was appointed minister of St. Outhbert's, Edinburgh. He early connected himself with the evangelical party in the church, and became in time its leader. The principal of his works are: "Discourses on the Evidence of the Jewish and Christian Revelations" (Edinburgh, 1815); "Account of the Life and Writings of Dr. John Erskine" (1818); and "Sermons" (3 vols. 8vo., 1829-'31), with a memoir by his son.

MONDAY (Lat. *Luna Dies*, Fr. *lundi*, Ger. *Montag*, the day of the moon), the second day of the week, which derives its designation from the Romans, who gave the names of the sun, moon, and 5 planets to the 7 days in modern use.

MONDOVI, an episcopal city of Piedmont, capital of a province of the same name, situated on the right bank of the Ellero, 1,810 feet above the sea, and 53 m. W. from Genoa; pop. 16,000. It is built partly on a hill, is walled, and has a citadel. The streets are adorned with many handsome edifices, among which are the cathedral of San Donato, 4 or 5 churches, and several convents. There are numerous schools and charitable institutions.* The

manufactures are of woollens, silks, &c. The city was founded in the 12th century by the people of the surrounding villages, as a place of refuge during the civil wars. It remained an independent republic until 1796, when it submitted to Amadeus of Savoy, titular prince of Achaia. On April 21, 1796, it was the scene of a battle between the French under Victor and the Sardinians under Colli, in which the latter were defeated with the loss of 2,000 men and 8 guns. In 1799 the city was subjected to acts of fearful violence by the French in punishment for its having risen against them.

MONE, FRANZ JOSEPH, a German historian, born at Mingolsheim, Baden, May 12, 1796. He studied and officiated as professor at the university of Heidelberg for nearly 10 years until 1827, when his work on statistics obtained for him the professorship of that science at Louvain, which he lost however after the Belgian revolution, when he returned to Heidelberg. In 1835 he became director of the Baden archives, and was appointed by the government to prepare a history of Baden, a portion of which has since appeared. His principal works are: *Geschichte des Heidenthums im nördlichen Europa* (2 vols., Heidelberg, 1822-'3), which may be regarded as the supplementary volume to the late Prof. Creuzer's "Symbolics and Mythology of the Ancient Nations;" an edition of *Reinardus Vulpes* (Stuttgart, 1832); *Uebersicht der Niederländischen Volksliteratur älterer Zeit* (Tübingen, 1838); and *Die Gallische Sprache und ihre Brauchbarkeit für die Geschichte* (Carlsruhe, 1851).

MONEY, the medium of exchange used by any people—at the present day, among civilized nations, confined entirely to metallic coins and bank notes. Money being an important instrument of association and combination in society, it is almost impossible to overestimate its power, or to exaggerate the disadvantages which follow from its absence or from a deficiency in its supply. The peculiar characteristic possessed by money, and that quality which gives to it its importance and influence, is the fact that in society it is the one thing which is acceptable to all men, and in exchange for which they will give any commodity which they possess. Labor being the cause of all wealth, the advance of any nation or community in material prosperity is dependent upon the extent to which labor is husbanded and directed to productive pursuits. The presence of a large supply of money in a country must therefore exert an important influence upon its advancement in prosperity, by furnishing the means wherewith labor can be paid, and thus preventing its waste; for it must be remarked that labor possesses a peculiarity in this, that "it is the only commodity that perishes at the instant of production, and that if not then put to use is lost for ever."—Very numerous and most dissimilar substances have been made to serve the purposes of money among the different people of the world. Of the aboriginal money of the American continent,

from the mounds in and adjoining the valley of the Mississippi, specimens have been found composed of lignite, coal, bone, shell, terra cotta, mica, pearl, carnelian, chalcedony, agate, jasper, native gold, silver, copper, lead, and iron, "which were fashioned into forms evincing a skill in art to which the descendants of the aborigines now surviving are strangers." Wampum, as is well known, was used by the Indians as currency, and consisted originally of strings of small spiral fresh water shells. The Carthaginians had a kind of money made of leather, which was probably of the nature of bank notes, and in the 18th century, Niccolo and Matteo Polo of Venice penetrated from Constantinople through Asia, to "Cambalu in Cathay," where they found the money then in use was made of the middle bark of the mulberry tree, cut in round pieces, and stamped with the mark of the sovereign. This money it was death to counterfeit, or to refuse in any part of the empire. In Britain, at as late a date as the Norman conquest (1066), two kinds of money were in use, known as "living money" and "dead money." The former consisted of slaves and cattle, which were usually transferred with the soil, and the latter of metal. The earliest recorded account of a purchase and sale is to be found in Gen. xxiii. Sarah, the wife of Abraham, being dead, he bought from Ephron a field in Machpelah for a burial place for her, and he "weighed to Ephron the silver which he had named in the audience," "four hundred shekels of silver, current money with the merchants." It will be observed that this money was not counted, but weighed; the money of that day being pieces of silver cut to certain weights, as shekels, talents, and drachms, but not coined. There is no evidence pointing to the practice of coinage by the Jews until about 144 B. C., under the Maccabees. In addition to the ordinary money, they had in use a description of "jewelry money," personal ornaments which in case of necessity could be used as currency. The invention of coinage is ascribed by Herodotus to the Lydians, to whom also by some authors is given the credit of the "invention of merchant money." By other writers the honor of the invention of coinage is given to the people of Ægina, who were among the first Greeks who applied themselves to commerce and navigation. It would appear probable, however, that to the Asiatics the world indebted for coinage as an art. It is doubtful whether any of the coins hitherto discovered date within some centuries of the original invention, though it is supposed that Lydian coins actually obtained indicate a high antiquity than that of any Greek specimens. In these coins the symbols were usually animal emblems, and it was not until after the age of Alexander that the portraits of sovereigns were introduced. From Greece the system of coinage penetrated into Gaul, and from the colony of Massilia, or Marseilles, extended to Britain, where coins somewhat similar to those issued by Philip and Alexander of Macedon took in part the place of

of the Celtic ring money. Asia Minor possessing native gold in abundance, its earliest coinage was of that metal; while, copper being found in Italy and Sicily, the money first used in these countries was of bronze. In the reign of Servius Tullius, king of Rome, 578-534 B. C., the pound weight of copper was first made current money; and from the fact that these coins bore upon them the images of cattle (*pecus*), they received the name of *pecunia*. It was not until 281 B. C. that the Romans issued silver coins, nor gold coins until 207 B. C. At the date of the invasion of Britain by Cæsar (55 B. C.), the ancient Britons had "both lozenge and gold money, or, instead of money, rings adjusted to a certain weight." They had also coins of tin, as well as of brass and iron. The brass of which the coins were made was imported, while the tin and iron were the product of their own mines smelted by themselves. It is related that under the emperor Claudius the coinage of the Romans took the place of that of the natives, and there circulated until the abandonment of the country by the conquerors, early in the 5th century A. D. About the close of the 2d century the Romans began to purchase peace from their enemies with money. Tribute money of this kind was paid by Lupus, the governor of the northern portion of Roman Britain, to the Caledonians. In the year 214 this was again done by the emperor Caracalla, who in consideration hereof was permitted by the chief of the nations of Germany to retire from that country. About this time Caracalla created a fictitious or base currency made of gilt copper, and of lead plated with silver, which was given to his poor subjects. It is recorded that about the middle of the 6th century the kings of the Franks were "permitted" by the emperor Justinian to coin money from Gallic gold, and to imprint it with their own portraits. The earliest coins of England, known to have been issued after the withdrawal of the Romans, are supposed to be the pennies of Ethelbert, king of Kent (560-616). By King Athelstan (930) it was decreed that throughout his entire dominions money should be uniform and be coined only in towns. The following places were indicated, with the number of coiners to each: Canterbury, Rochester, London, Winchester, Lewes, Hastings, Chichester, Southampton, Wareham, Exeter, and Shaftesbury. At all towns not named in this list there was to be but one coiner. This decree also makes mention of the fact that the clergy of superior rank shared with the king the privilege of coinage. Again, in the year 975, King Edgar decreed that the coinage should be uniform, from which it would seem that Athelstan's decree had not been fully complied with. During the reign of Canute (1016-'35) no fewer than 87 cities and towns were points at which the coinage of money took place, as is shown by specimens actually collected. In Saxon England the pound currency consisted of an actual pound of silver; and while it is well settled that the pound was coined into 240 pennies, authorities differ wide-

ly as to the number of shillings in the pound. Some have it 48 shillings of 5 pennies each, some 60, and some but 20. The date of the earliest use of the term "sterling" to denote the standard money of England has given rise to much discussion, and it has been pretty clearly determined as having been adopted in the reign of William the Conqueror, although some authorities fix it as late as Richard I. or John. Henry I. in 1108 attached severe penalties to the counterfeiting of money, and many of the pennies and halfpennies being bent and broken, he decreed that no one should refuse to receive them if they were entire. Prior to this time the halfpenny had been semicircular, being one half part of a penny; but Henry now ordered that halfpennies should in future be regularly coined. During the reign of Stephen the money had become very much debased, as well by the frauds of the legally constituted coiners, as from the fact that "almost every baron had usurped the prerogative of issuing money by his own authority." It does not seem that up to this time the right of bishops and abbots to coin money had been disturbed by any of the monarchs of England. At the commencement of his reign (1154) Henry II. found the money so much debased and reduced in value from various causes, that he provided for a new coinage, and punished all those convicted of tampering with it. In 1207 the places of coinage were still very numerous. In 1222 dies were given to the officers for the coinage of pennies, halfpennies, and farthings of silver. In 1248 it was found that the money of England had been so clipped and otherwise defaced that its real worth bore no proportion to its nominal value. Henry III. hereupon decided that the old coins should be brought to the mint and exchanged for new ones, weight for weight, which was the cause of such severe loss to the holders as to induce great complaint. In the reign of the same monarch, 9 years later, gold coins were made of the purest metal, and the standard was fixed at 20 times that of silver. To this the opposition was so great that the king decreed that all holders of it might have it exchanged for silver at his royal exchange on submitting to a deduction of 2½ per cent. Prior to this time gold had never been rated so high in comparison with silver. It may here be mentioned that by some writers it has been thought that no gold was coined in England earlier than the reign of Edward III. (1327-'77), but this is an error. In 1279 Edward I. gave orders for a new coinage of halfpennies and farthings, providing at the same time that the old, which was principally of mere fractions of pennies cut of sizes to suit, should no longer be current. Holders of the old coin were however allowed to exchange it at the mints for new, by paying a certain percentage as "change" or "exchange," as it was termed. During the same reign, 20 years later, so much trouble, annoyance, and loss were suffered from foreign coins of inferior value, known as "pollards," "crockards," &c., that it was en-

acted that all importers of such money should be punished by death and the confiscation of their property. All persons arriving from abroad were to be searched, and those having such money were to be immediately imprisoned. All good foreign money was to be taken forthwith on its arrival to the exchange, and all false English money imported was to be seized. No person was allowed to sell wool, hides, skins, lead, or tin, except for good sterling money, silver stamped at the king's exchange, or for a good and sufficient quantity of merchandise; and no money or bullion was to be taken out of the dominions without a license from the king, under penalty of seizure. Persons going abroad, or coming to England, were to be furnished at Dover with a quantity of money of the country to which they were going, sufficient to pay their expenses. The following year (1300) Edward positively prohibited the circulation of any money not of his own coinage. In 1301 he diminished the weight of the pound sterling 8 pennies, equal to one per cent. This was "a departure from the ancient strict and honorable adherence to the integrity of the national money; and a breach, once begun, was with less scruple enlarged by the succeeding kings." Edward II., having married a daughter of the king of France, gave permission to the French merchants to trade with England, and return with their goods and money, notwithstanding the edicts of preceding monarchs against the exportation of coin and bullion. In the reign of Edward III. (1335), among the extraordinary means which were taken to prevent the importation of money of foreign coinage from abroad, may be mentioned that of obliging innkeepers to be sworn to search their guests for the detection of such money. Exchanges were established at Dover, London, Yarmouth, Boston, Kingston, and Hull, for furnishing to travellers going abroad foreign money. This monarch, having by 1344 exhausted his exchequer, and embarrassed himself with debts, in his unsuccessful attempts to conquer France, ordered that in future 266 pennies should be made from the pound sterling, thus defrauding his creditors of 10 per cent. of their claims. Two years subsequently he increased the number to 270 pennies. In 1394 it was decreed that no silver money should be melted for the manufacture of plate or for any similar purpose. Counterfeiting of English money would seem to have been a very common practice in those days; and in 1416 parliament passed an act declaring it treason to counterfeit the money of the kingdom, and providing for the punishment by the judges of importers of base coin. Five years later the currency was in so bad a state that a law was passed by parliament providing that all gold money should be passed only by weight, and that all light and vitiated coins should be taken to the tower to be recoinced; in consideration of the loss sustained by the holders, the king remitted the usual charge for coinage. In the reign of Henry VII. (1504) a

law was passed against either taking English money into Ireland, or bringing Irish money into England. The following year a trifling number of shilling pieces were coined, being the earliest known to have been made. Under Henry VIII. enactments against the exportation of money, plate, and jewels were again passed; and in this reign (1528) silver things were coined for the last time. In the reign of Edward VI. (1551) the currency reached its worst condition of depreciation, and was "in such a state of confusion and fluctuation, that the sellers scarcely ever knew what value they were to receive for their goods," when the king applied active and vigorous measures for correcting the evil by raising the standard. Queen Elizabeth signalized the beginning of her reign by restoring the silver coin to a higher standard of purity than had been known since the accession of Henry VIII. In 1601 she caused to be coined for Ireland shillings, sixpences, and threepences of a baser kind, and established offices for exchange between the two countries. For many years the tradesmen of London had made and issued leaden tokens, which circulated instead of copper coins. This circulation was, however, to a great extent stopped about the beginning of the 17th century by the government; and the more general use of regular coins gradually took their place. James I. in 1613 debased a portion of the coin, having for some unaccountable and unexplained reason coins in circulation of two qualities of fineness. In 1627 Charles I. issued a proclamation, saying in effect that the buying, selling, and exchanging of all manner of coins and bullion were prerogatives of the crown, which from that time forth he intended to exercise; he interdicted the goldsmiths from prosecuting the business in any of its branches, and appointed Lord Holland and his deputies to have "the office of our changes, exchanges, and outchanges whatsoever in England, Wales, and Ireland." In 1682 he granted permission to the East India company to export to Persia and India £40,000 in foreign gold bullion; and being desirous of cultivating friendly relations with Philip IV. of Spain, he authorized under certain restrictions the export of the precious metals to the Spanish Netherlands. According to D'Avenant, the entire gold and silver coinage of England for 100 years, from 1558 to 1659, was of gold £3,723,000, and of silver £16,109,476, making in all £19,832,476. By the same authority it is estimated that in the year 1600 the amount of gold and silver currency in England did not exceed £4,000,000, and that in 1711 it did not exceed £12,000,000. In 1676, Charles II. being then on the throne, the money called in and recoinced. This amounted to £800,000; and by estimating that coinage as one seventh, and giving an allowance for money hoarded, writers of that day put the total currency of the country at £6,000,000. One of the most memorable events in the monetary

history of England, or of the world, was the establishment of the bank of England, April 25, 1694, William and Mary being then the sovereigns of England. (See BANK, vol. ii. p. 573.) This institution is indebted for its existence to the wants of the government, which had been obliged to pay interest at rates varying from 20 to 40 per cent. per annum. It at once relieved the government from embarrassments, and became the principal means of the success in the campaign of 1695, thus aiding materially and decidedly in bringing about the peace of Ryswick in 1697. The following table, derived from the "indentures" made with the masters of the mint, will exhibit the number of pounds, shillings, and pence which have at various times in England been coined out of a pound of silver, with the standard of fineness:

Dates.	Fine Silver.		Alloy. \textsterling s. d.		
	oz. dwt.	oz. dwt.			
Before A. D. 1800.....	11 2	0 18	1	0	0

1601, 43 " ".....	11 2	0 18	2	2	0

At the present day the standard of fineness is the same, but the weight of the coins has been reduced, the shilling weighing but 87 grains, and a pound of silver thus producing 66 $\frac{1}{8}$ shillings.—The currency of Scotland prior to the time of Robert I. (1306) was of the same standard as that of England at the same date, 1 oz. 2 dwt. of fine silver, and 18 dwt. of alloy, making one pound; but that standard was reduced gradually, until in 1424 it represented £1 17s. 6d. From this time forth it was rapidly reduced, standing in the under mentioned years as follows: 1451, £3 4s.; 1456, £4 6s.; 1475, £7 4s. In 1529, 11 oz. of fine silver and 1 oz. of alloy represented £9 12s.; in 1556, £13; and in 1565, £18. In 1571, 9 oz. of fine silver and 3 oz. of alloy were £16 14s.; in 1576, 8 oz. of fine silver and 4 oz. of alloy were £16 14s. In 1579, 11 oz. of fine silver and 1 oz. of alloy were £22; in 1581, £24; in 1597, £30; and in 1601, £36. In 1738, 11 oz. 2 dwt. of fine silver with 18 dwt. of alloy were £37 4s. The earliest coinage of Scotland is believed to have taken place in the reign of Alexander I., 1106–1124.—The early history of the money of England, in one respect at least, answers to a considerable extent for a history of the currency of all countries of the same era. Fluctuations, debasement, and feeble efforts to restore it, mark the progress of time. In France, Pepin, the first of the Carlovingian race, in his reign (752–768) increased the number of pennies in a

pound of silver from 240 to 264. This abuse was however corrected in the succeeding reign by Charlemagne. But Philip I. in his reign (1060–1108) caused his *deniers* or pennies to be made of $\frac{1}{2}$ copper and $\frac{1}{2}$ silver. The depreciations of the coin have since then been very great and numerous.—In America, "the several provinces in their infancy," says an English writer in 1767, "had but little trade, and consequently little money. The tools, utensils, and necessities for planting they were at first supplied with from Britain, involved them in debt before they were able to raise goods for exportation to pay their creditors; and the goods they first raised were often so ordinary in quality or so little in quantity that they were able to export to a foreign market, that the net proceeds of the same often turned out poorly; by which means the planters remained continually in debt to the British merchants, and occasioned the balance of trade to be always against them; and having neither goods nor cash sufficient to remit to their creditors, the consequence has been that many bad debts have been made and great losses sustained, as the merchants of Great Britain have but too fatally experienced." As the northern colonies improved in their condition, the British merchants received their claims in part; but this "prevented the cash staying with them" (the colonists), "and obliged them to ship it off with their other merchandise toward paying their debts." The provinces were now driven to the issue of paper money for circulation at home, and the writer above cited assures us that "gold and silver" were "as much merchandise as any they dealt in." This state of things went on, and with it the rate of exchange advanced rapidly, as will be seen by the following table:

Years.	Sterling exchange in Mass. currency.	Value of an oz. of silver in currency.
1702.....	183	6s. 10 $\frac{1}{2}$ d.
1706.....	185	7 0
1713.....	150	8 0
1716.....	173	9 8
1717.....	225	12 0
1722.....	270	14 0
1729.....	340	18 0
1730.....	350	20 0
1737.....	500	26 0
1741.....	550	28 0
1749.....	1,100	60 0

The currency of Rhode Island suffered such a depreciation between 1744 and 1759, that while in the former year it required £450 to obtain £100 sterling, in the latter it required £2,300. However, in or about the year 1767, measures were taken to place the currency of some of the colonies on a better footing. What was the nature of the reforms so made we are not informed; but in 1767 the following were the rates of sterling exchange in the provinces named: Massachusetts, 133 $\frac{1}{4}$; New York and East Jersey, 175 to 171 $\frac{1}{4}$; Pennsylvania and West Jersey, 165 to 160 $\frac{3}{4}$; Virginia, 125; Maryland, 145; North Carolina, 145; South Caro-

lina, 700; Georgia, 100; Jamaica, 140; Barbados, 135; Nevis and Montserrat, 175; Antigua and St. Christophers, 165. (For American revolutionary and national currency and coinage, see BANK, and COINS; and for further information, see MINT, and NUMISMATICS.)

MONGE, GASPARD, a French mathematician, born in Beaune in 1746, died July 28, 1818. In 1766 he was a tutor in the school of engineers in Mézières, and was afterward assistant to Bossut, and also to the abbé Nollet, whom he succeeded in the chair of natural philosophy. While in this school he made numerous experiments in physics and chemistry, and investigations into the principles of geometry, which led to the foundation of a new and important department of that science, to which he gave the name of descriptive geometry. In 1780 he was made a member of the academy of sciences, and soon after professor of physics in the lyceum of Paris. During the revolution he was for a short time minister of marine; and when materials for equipping the army were to be suddenly provided, and almost created, he devoted himself with great energy to the work. It was through his exertions that the normal and polytechnic schools were established, the one to supply teachers, and the other to furnish engineers; he taught in both schools. He accompanied the army into Italy and Egypt, where he formed a lasting friendship with Bonaparte, and on his return was made president of the Egyptian commission, head of the polytechnic school, and member of the senate with the title of count of Pelusium; but on the fall of Napoleon he was deprived of all his honors and emoluments. He was the first who applied the differential calculus to the general theory of surfaces. His best known work is the *Géométrie descriptive* (4th ed., 1820), which has never been surpassed as an elementary text book.

MONGOLIA, a country of Asia, and at present a part of the Chinese empire, lying between lat. 35° and 52° N. and long. 82° and 123° E., bounded N. by the Russian government of Irkootsk in Siberia, N. E. and E. by Mantchouria, S. by the Chinese provinces of Chi-li and Shan-si and the Yellow river, S. W. by Kansu, and W. by Cobdo and Ili; area, 1,400,000 sq. m.; pop. 2,000,000. It is chiefly a high plain, 8,000 feet above the sea, almost destitute of wood and water. In the central part is the great sandy desert of Gobi, which stretches from N. E. to S. W. with an area estimated at 600,000 sq. m. The chief mountain ranges of Mongolia are the Altai and its various subordinate chains, which extend eastward under the names of Tanguoo, Khangai, and Kenteh, as far as the Amoor; and the Ala-shan and In-shan ranges, which commence in lat. 42° N. and long. 107° E., and run N. E. and N. to the Amoor in lat. 53° N. The rivers of Mongolia are chiefly in the north. The Selenga, Orkhon, and Toola unite their streams and flow into Lake Baikal. The Kerlon and Onon rise near each other on opposite sides of the Kenteh range, and

flow in a N. E. direction to the Amoor. In the south, the Siramuren and its branches unite in the Lian river. Lakes are numerous, and some of them are large. South of the desert of Gobi are the Oling and Dzaring, and the Koko-nor or Blue sea, which according to the Chinese accounts is 190 m. in length and 60 in breadth. In the N. W. part of the country lakes abound, the largest of which are the Ursa-nor, Altai-nor, Alak-nor, and the Iki-aral.—Mongolia is divided into 4 principal regions: 1, Inner Mongolia, lying between the great wall and the desert of Gobi; 2, Outer Mongolia, between the desert and the Altai mountains, and reaching from the Inner Hingan to the Tien-shan; 3, the country about Koko-nor; 4, Uliassutai and its dependencies. Inner Mongolia is divided into 6 circles and 24 tribes, which are again divided into 41 standards, each comprising about 2,000 families commanded by hereditary princes. The Khotchin and the Ortous are the principal tribes. Another large tribe, the Taakhara, occupy the region immediately north of the great wall. Outer Mongolia is divided into 4 circles, each of which is governed by a khan or prince who claims descent from Genghis Khan. The Khalkas are the principal tribe, and their 4 khans are divided into 86 standards, each of which is restricted to a particular territory from which it is not allowed to wander. The country about Lake Koko-nor is occupied by Tourgoutia, Beshoita, Khalkas, and other tribes, arranged in 29 standards. Uliassutai is a town of 200 houses in the W. part of Mongolia, and lies in a well cultivated valley on the river Ili. Its dependent territories comprise 11 tribes of Khalkas divided into 81 standards.—Mongolia is supposed to be rich in metals and minerals but little is accurately known of its natural history. Its immense plains and gloomy forests are inhabited by multitudes of wild animals, among which are the elk, the stag, the wild goat, the wild ass, the yak, the brown and black bear, the ounce, and two species of tiger, besides hares, squirrels, and foxes. The wolves of Mongolia are large and fierce, and prefer to attack men rather than animals; they will pass through a flock of sheep to attack the shepherd. The Mongols wage against them incessant and destructive war. The announcement that a wolf has made its appearance in a neighborhood is a signal for every man to mount his horse. The horsemen run it down, capture it with a spear, drag it to the tents, and after torturing it for some time skin the animal alive and turn it loose in that condition. Among the birds of Mongolia are pheasants and eagles. The eagle is very common, and makes its nest where it places the people abstaining from molesting it in any way. The double-humped or Bactrian camel exists in both the wild and domesticated state. This camel endures the most intense cold not only without injury but apparently with pleasure. It delights to face the north wind in winter, or to stand motionless in places exposed to the severest blasts. Its milk is excellent, and

supplies large quantities of butter and cheese. The flesh is not esteemed by the Mongols, who generally eat only the hump.—The soil of Mongolia is poor, and little of it is fit for cultivation on account of the want of moisture, neither rain nor snow falling in sufficient quantities except on the acclivities of the mountain ranges. From the great elevation of the country and the dryness of the atmosphere, the climate is excessively cold. Mercury often remains frozen for weeks in succession. The winter lasts 9 months, and is immediately succeeded by summer, in which there are sometimes days of stifling heat. The nights, however, are almost invariably cool. At all seasons the weather is subject to great and sudden changes. In the southern part of the country, where the Chinese emigrants have introduced agriculture, it is noticed that the temperature has risen with the increase of cultivation, so that kinds of grain which formerly would not ripen because of the cold are now raised with success. In this part of Mongolia there are towns and villages, and a portion of the native race have adopted a settled life.—The Mongols belong to the great Mongolian division of mankind, which takes its name from them. They belong also to the great nomadic family of central Asia, who in Europe are commonly known under the vague general designation of Tartars. They are generally stout, squat, swarthy, and ugly, with high and broad shoulders, pointed and prominent chins, long teeth distant from each other, eyes black, elliptical, and unsteady, thick, short necks, bony and nervous hands, and short muscular arms. Their stature is equal to that of Europeans. They are, with few exceptions, nomadic in their mode of life, living in tents and subsisting on animal food, the produce of their flocks and herds. The Mongol tent for about 8 feet from the ground is cylindrical in form; it then becomes conical like a pointed hat. Its woodwork is composed below of a trellis-work of crossed bars which fold up and expand at pleasure. Above these, a circle of poles, fixed in the trellis-work, meets at the top, like the sticks of an umbrella. Over the woodwork is stretched a thick covering of coarse felt. The door is low and narrow, and is crossed at the bottom by a beam which serves as a threshold. At the top of the tent is an opening to let out smoke, which can at any time be closed by a piece of felt hanging above it, to which is attached a long string for the purpose. The interior is divided into two compartments, that on the left being for the men, while that on the right is occupied by the women, and is also used as a kitchen, the utensils of which consist chiefly of large earthen vessels for holding water, wooden pails for milk, and a large bell-shaped iron kettle. A small sofa or couch, a small square press or chest of drawers, the top of which serves as an altar for an idol, and a number of goats' horns fixed in the woodwork of the tent, on which hang various utensils, arms, and other articles, complete the furniture of this primitive habita-

tion. The odor pervading the interior of the Mongol tent is, to those not accustomed to it, disgusting and almost insupportable. "This smell," says M. Hue, "so potent sometimes that it seems to make one's heart rise to one's throat, is occasioned by the mutton grease and butter with which every thing on or about a Tartar is impregnated. It is on account of this habitual filth that they are called *Tao-Ta-Dze*, 'stinking Tartars,' by the Chinese, themselves not altogether inodorous, or by any means particular about cleanliness." Household and family cares among the Mongols are assigned entirely to the women, who milk the cows, make butter and cheese, draw water, gather fuel, tan skins, and make cloth and clothes. The occupation of the men consists wholly in conducting the flocks and herds to pasture, which, as they are accustomed from infancy to horseback, is an amusement rather than a labor. They sometimes hunt wild animals for food or for their skins, but never for pleasure. When not on horseback the men pass their time in absolute idleness, sleeping all night and squatting all day in their tents, drinking tea or smoking. Their education is very limited. The only persons who learn to read are the lamas or priests, who are also the painters, sculptors, architects, and physicians of the nation. The training of the men who are not intended for priests is confined to the use of the bow and the matchlock, and a thorough mastery of horsemanship. M. Hue says: "When a mere infant the Mongol is weaned, and as soon as he is strong enough he is stuck upon a horse's back behind a man, the animal is put to a gallop, and the juvenile rider, in order not to fall off, has to cling with both hands to his teacher's jacket. The Tartars thus become accustomed from a very early age to the movement of the horse, and by degrees and the force of habit they identify themselves as it were with the animal. There is perhaps no spectacle more exciting than that of Mongol riders in chase of a wild horse. They are armed with a long heavy pole, at the end of which is a running knot. They gallop, they fly after the horse they are pursuing, down rugged ravines and up precipitous hills, in and out, twisting and turning in their rapid course, until they come up with their game. They then take the bridle of their own horse in their teeth, seize with both hands their heavy pole, and bending forward throw, by a powerful effort, the running knot around the wild horse's neck. In this exercise the greatest vigor must be combined with the greatest dexterity in order to enable them to stop short the powerful untamed animals with which they have to deal. It sometimes happens that cord and pole are broken; but as to a horseman being thrown, it is an occurrence we never saw or heard of. The Mongol is so accustomed to horseback that he is altogether like a fish out of water when he sets foot on the ground. His step is heavy and awkward, and his bowed legs, his chest bent

forward, his constant looking about him, all indicate a person who spends the greater portion of his time on the back of a horse or a camel." The Mongols marry very young, and their marriages are regulated entirely by their parents, who make the contract without consulting the young people at all. No dowry is given with the bride, but on the contrary the bridegroom's family pay a considerable price for the maiden. A plurality of wives is permitted, but the first wife is always the mistress of the household. Divorce is very frequent, and is effected without the intervention of either the civil or the ecclesiastical authorities. The husband who wishes to repudiate his wife sends her back to her parents, without any formality except a message that he does not require her any longer. This proceeding does not give offence, as the family of the lady retain the cattle, horses, and other property given to them at the time of the marriage, and have an opportunity of selling her over again to a fresh purchaser. The women, however, are not oppressed, and are not kept in seclusion. They come and go at pleasure, ride out on horseback, and visit freely from tent to tent. In their manners and appearance they are, like the men, haughty, independent, and vigorous. The chiefs of the Mongol tribes and all their blood relations form an aristocracy who hold the common people in a mild species of patriarchal servitude. There is no distinction of manners nor of mode of living between these classes; and though the common people are not allowed to own land, they frequently accumulate considerable property in herds and flocks. Those who become lamas are entirely free.—The ancient religion of the Mongols was a species of Shamanism, but in the 13th century they embraced Lamaism. Their religious system at the present day is similar to that of Thibet, and they acknowledge the spiritual supremacy of the grand lama at Lassa. They are very devout, and are generous and even prodigal in their contributions for religious purposes. Mongolia abounds in well endowed lamaseries constructed of brick and stone, with elegance and solidity, and ornamented with paintings, sculptures, and carvings. The most famous of these monasteries is that of the Great Kouran, on the bank of the river Toola, in the country of the Khalkas. Thirty thousand lamas dwell in this lamasery, and the plain adjoining it is always covered with the tents of the pilgrims who resort thither from all parts of Tartary. In these lamaseries a strict monastic discipline is maintained, but each lama is at liberty to acquire property by practising as a physician, by casting horoscopes, or by working as a sculptor or painter, or in any occupation not inconsistent with his priestly character. Almost all younger sons of the free Mongols are devoted from infancy to the priesthood, and this tendency to monasticism is encouraged by the Chinese government in order to keep down the growth of population among the Mongols. Almost every lamasery of the first class possesses a living Bud-

dha, who like the grand lama of Thibet is worshipped as an incarnation of the deity. The influence of these personages is very great, and the Chinese emperors, who are constantly in dread of the Mongols, watch the living Buddha with anxious care, and spare no pains to conciliate them and to win over to their interest those who manage these deities.—The trade between China and Russia passes through Mongolia at Kiakhta, a town on the borders of the two countries. This trade, which is entirely under the supervision of Mantchoo officers, introduces among the Mongols European goods in moderate quantities.—The Mongolian is the least known of all the languages of Asia. It was reduced to writing about the 14th century, and its literature consists in great part of translations of Chinese books. It embraces, however, a few original histories and many poems relating chiefly to Genghis Khan and to Tamerlane. It is with Genghis Khan that the history of the Mongols properly commences. This greatest of conquerors was born about 1160 and died in 1227. At his birth the Mongols were divided into petty and discordant tribes. He united them into one nation, inflamed them with religious and warlike enthusiasm, and led them forth to conquer the world. Under his banners they subjugated the whole of Tartary, a great part of China, Corea, Afghanistan, Persia, and Russia. Under his son and successor, Hulei, the conquest of China was continued, the caliphate of Bagdad was overthrown, the sultan of Iconium in Asia Minor made tributary, and Europe overrun and devastated as far as the Oder and the Danube. The Mongol empire was at this time the most extensive that the world has ever seen. In 1260 Kublai Khan, the grandson of Genghis, completed the conquest of China. He is known in Chinese history as the emperor She-tsu, and as the founder of the 24th or Yuen dynasty. He was a vigorous and magnificent ruler, and the grand canal of China, which was dug during his reign, is a lasting monument of his enlightened policy. The Venetian Marco Polo was among the foreigners who were liberally entertained and employed at his court. Under him and his descendants the Mongols were masters of China for upward of a century, till in 1368 the native race rose in insurrection and established their independence under the Ming dynasty. The Mongol empire was split into several independent sovereignties in the 13th century, but was reunited and even enlarged by Tamerlane (1335-1405), who almost rivalled Genghis Khan as a warrior and a conqueror. After his death the Mongol power slowly declined, and in the early part of the 17th century they gradually submitted to the sovereignty of the Mantchoo emperors of China. They yield, however, little more than a nominal obedience, and are still a haughty and independent race, proud of their descent from Genghis, and fully conscious that their ancestors were once the masters of the world. The Chinese government watches and humors

them with incessant anxiety, and conciliates their chiefs by annual presents of considerable value.

MONGOLIAN RACE, one of the great ethnological divisions of mankind. Its characteristics are: an olive yellow skin; thin, coarse, and straight hair; scanty beard; broad, flattened face, low forehead, wide and small nose; oblique eyes, thick lips, and a stature inferior on the whole to that of the Caucasian race, but superior to the Malay. The head is less compressed at the sides than in the other races, so that it presents, when viewed in front, a more rounded contour. The complexion is always sufficiently light to show a flush, and in the extreme north is sometimes decidedly florid. Prof. Dieterici, an eminent Prussian statistician, in 1859 estimated the number of the Mongolians at 528,000,000; this, however, is probably an overestimate, though they are certainly more numerous than any other race. Dr. Pickering in "The Races of Man" includes the American Indians among the Mongolians. He says: "The arctic regions seem exclusively possessed by the Mongolian race; which beside is diffused through a greater variety of climates than any other, and over a far larger area. This comprises about one half of Asia, and with a slight exception all aboriginal America, or more than two fifths of the land surface of the globe. Notwithstanding the recent encroachments, the greater portion of the American continent is still inhabited by Mongolian tribes; and while some of them wander toward the north further than civilized man has hitherto been able to follow, others are still the nearest dwellers to the southern pole." By most writers, however, the American Indians are held to be a distinct race, and the term Mongolians is restricted chiefly to the following nations: the Mongols proper, the Mantchoos, Coreans, Chinese, Thibetans, Anamites, Burmese, Siamese, Japanese, Samoyeds, Koriaks, Oorals, Ostiaks, Kamtchatdals, Finns, Laplanders, Esquimaux, and the various tribes inhabiting Turkestan or Independent Tartary, who are commonly called Tartars by Europeans, though the term is not used by the people to whom it is applied.

MONGOUS. See *LEMUR*, vol. x. p. 452.

MONITEAU, a central co. of Mo., bounded N. E. by the Missouri river, and drained by Saline, Moreau, and Moniteau creeks; area, 400 sq. m.; pop. in 1856, 6,402, of whom 593 were slaves. Iron, limestone, and excellent coal are found; and the soil is generally fertile. The productions in 1850 were 843,914 bushels of Indian corn, 24,540 of wheat, 68,615 of oats, and 21,674 lbs. of wool. There were 8 grist mills, 3 saw mills, 9 churches, and 780 pupils attending public schools. Capital, California.

MONITOR, the common name of many of the old world slender-tongued lizards of the family *Cercasidae*, and genus *Saurus* (Merr.). They have an elongated head; long, extensile, thick, fleshy tongue, enclosed in a sheath at the base; no teeth on the palate, those of the jaws

flattened at the roots, lodged in a common groove or alveolus without internal border, with the crowns generally pointed and curved backward; the neck long; the head and body covered with tuberculated non-imbricated scales; the tail very long, sometimes containing 80 vertebrae, capable of reproduction, non-prehensile, compressed and keeled or rounded according as the species are aquatic or terrestrial; no femoral pores nor dorsal crest; eyes with 2 distinct movable lids; feet large, with 5 unequal, non-palmated toes, furnished with strong claws; in the fore limbs the 1st finger is the shortest, and the 3d and 4th longest; in the posterior the 4th is 3 times as long as the 1st. The monitors form a natural transition to the serpents, in the suspension of the bones of the face to the cranium and their mobility, in the incomplete circle of the orbits, in the long and narrow lower jaw loosely united in the middle, in the tongue, and in the scaly covering. The colors vary from black to more or less deep green, with lighter spots arranged in various ways so as to resemble mosaic work; many of these patterns are so admirable that the skin has been used to cover jewel boxes and cases requiring a material which will not readily tarnish by ordinary friction. These reptiles are, next to the crocodiles, the largest of living saurians; they live either in the neighborhood of rivers, or in dry sandy regions, the former class being said to give notice of the presence of crocodiles by a whistling sound, whence their common name; they do not climb trees nor scale precipices, though they run rapidly on the ground, in a sinuous serpent-like manner on account of the length of the tail. Their food consists principally of the larger coleopterous and orthopterous insects; they also eat the eggs of aquatic birds and reptiles, and such lizards, small tortoises, fish, and mammals as they are able to overpower. If the American genus *Heloderma* (Wieg.) be excluded (and this is now generally placed near the lizards proper), the true monitors, of which fewer than 20 species are described, are confined to Asia, Africa, and Australasia. Of the genus *Varanus*, erroneously called *tupinambis* by Daudin, the best known aquatic species is the monitor of the Nile (*V. Niloticus*, Fitz.), common in the rivers of Egypt and of western and southern Africa, and attaining a length of 5 or 6 feet, of which the head is about $\frac{1}{4}$, the neck $\frac{1}{3}$, and the tail nearly one half; the teeth are 30 above and 22 below; the general color above is greenish gray with black dots, with 4 or 5 yellow V-shaped marks pointing backward upon the nape, bands of yellow eye-like spots on the back, a wide black band on the shoulder, and a narrow one edged with pale green on each temple; whitish below, with brown transverse bands, and the claws black. From its supposed usefulness in devouring the eggs of the crocodile, it was highly esteemed by the ancient Egyptians, and was frequently represented on their monuments. Other aquatic species are found in the East Indies, and in Australia and

its archipelago. Of the terrestrial monitors the best known is the *V. acincus* (Merr.), the skink of the ancients, the land crocodile of Herodotus, the *ouaran* of the Arabs, and the genus *psammosaurus* of Fitzinger. This is very common in the sandy deserts of Egypt; it is about 8 feet long, of which the rounded tail is more than one half. The color of the upper parts varies from brown to yellow, spotted and banded with one or the other; it is less carnivorous and ferocious than the aquatic monitors. Another species is found in the island of Timor, of a brownish color marked with black and yellow, about 2 feet long.—Cuvier, in his *Ossemens fossiles*, has referred to the family of monitors several gigantic fossil reptiles, as the *protosaurus* (H. de Meyer), 8 feet long, from the coppery schists of Germany; the *mosasaurus* (Conyb.), over 30 feet long, intermediate between the monitors and iguanas, from the calcareous strata of Maestricht; the *geosaurus* (Ouv.), 12 or 18 feet long, from an iron mine near Mannheim; and the *megalosaurus* (Buckland), about 40 feet long, from the vicinity of Oxford, the last placed by Pictet among the dinosaurians, or those having certain mammalian characters.—The name of monitor is sometimes given to some American lacertian lizards, especially of the genus *salvator* (Dum. and Bibr.), more properly called safeguards, corresponding in part to *tupinambis* (Daud.) and *tejus* (Merr.), and to *monitor* (Fitz).

MONK. See MONACHISM.

MONK, GEORGE, duke of Albemarle, an English general, born at Potheridge, Devonshire, Dec. 6, 1608, died in London, Jan. 8, 1670. He was of a good family, and at the age of 17 he entered the military service, and was present in an expedition sent against Spain, and in that to the isle of Ré. For several years he served in the Low Countries, and was made a lieutenant-colonel in the force which Charles I. employed against the Scotch in 1638. On the breaking out of the Irish rebellion in 1641, he was sent to Ireland, with the rank of colonel. His conduct there was so good, that the lords justices would have made him governor of Dublin, but the parliament party had possession of the place, and he was ordered to England by the commander of the royal army. His political opinions were favorable to the parliamentary cause, and when he arrived in England he was deprived of his regiment by the king's order; but he was allowed to go to Oxford, where he won the royal favor, and was made a major-general in an Irish force, then employed in England. This force was defeated by Fairfax, and Monk made prisoner. After being confined for some time in the tower of London, he accepted service in the parliamentary army, and returned to Ireland in 1646, in company with the deputy, Lord Lisle. The king was so strong there that they effected nothing, and returned to England. Again going to Ireland, with command of the army in the north, he was distinguished for his energy and cruelty. A treaty which he made with the Irish in 1649

was condemned by parliament, and he was unemployed for some time thereafter. Cromwell, when he commenced the war with Scotland in 1650, made Monk colonel of a foot regiment, and lieutenant-general of the artillery. He performed important services, and was appointed to the chief command in Scotland in 1651. He completed the conquest of that country, which he governed with considerable skill and was a commissioner to bring about the union of England and Scotland that existed in the days of the protectorate, and acquitted himself well in the office. He served in the navy against the Dutch, and had his share in the victories that were won. At first he was opposed to Cromwell's usurpation, but an interview with the protector changed his opinions; and he was again sent to Scotland, where he quelled a rebellion. For a time he governed that country alone; and when a council of state was there established, he controlled its action. His rule was arbitrary, but not severe, and the Scotch prospered under it. The royalists early had hopes that a restoration could be effected through his aid, and Charles II. wrote a letter to him, which he sent to Cromwell. While Cromwell lived, Monk knew it was impossible to act for the Stuarts, and he devoted himself to the immediate duties of his station with substantial success. The protector is represented to have been jealous of him, but on his death-bed he recommended him to his son and successor. Monk gave good advice to Richard Cromwell, and showed every disposition to support his government, proclaiming him in Scotland. When Richard failed, and matters were falling into confusion in England, Monk marched with his army to London, where he declared for a new parliament, the government having virtually passed into his hands. He might have become lord protector, but his ambition was not of a lofty order. For months after he left Scotland it was uncertain what his purpose was; but at length, in the spring of 1660, he took measures for the restoration of the house of Stuart. Charles II. returned to England, and Monk was lavishly rewarded with offices, titles, and estates. He was made Baron Monk, earl of Torrington, and duke of Albemarle; the order of the garter was bestowed upon him, and he received the offices of privy councillor, master of the horse, and commander of the forces. Later he was made lord lieutenant of the counties of Middlesex and Devonshire, and of the borough of Southwark. In 1664 he was placed at the head of the admiralty, and in 1667 at the head of the treasury. His income was £12,000, an enormous one for those days, and exceeded that of only two other subjects, the duke of Buckingham and the duke of Ormond. In 1668 he served in the fleet against the Dutch, with no distinction. On his return his health failed, and he died of dropsy. He was buried in Westminster abbey, and the king attended his funeral. His titles and estates descended to his son Christopher, who died without issue.

1688, and the family became extinct the same year that saw the final fall of the royal house which George Monk had vainly restored to the British throne. Guizot says of Monk: "He was a man capable of great things, though he had no greatness of soul."—See Skinner, "Life of Monk" (London, 1751), and Guizot, *Monk, chute de la république et rétablissement de la monarchie en Angleterre* (Paris, 1851; English translation, edited by Lord Wharncliffe).

MONK, JAMES HENRY, an English prelate and author, born in Huntingford, Herts, early in 1784, died at his palace, Stapleton, near Bristol, June 6, 1856. He was a nephew of Sir James Monk, formerly chief justice of Montreal. He studied at the Charterhouse, and at Trinity college, Cambridge, of which he became a fellow in 1805. In 1807 he became assistant tutor, and in 1808 succeeded Porson as regius professor of Greek, but resigned that office on his promotion to the deanery of Peterborough in 1822. In 1830 he became bishop of Gloucester at the recommendation of the late duke of Wellington. He was a devoted member of the high church party, but took little part in political debates in the house of lords. His principal work is the "Life of Bentley" (2 vols. 4to., 1831), of which a second and revised edition appeared in 1833. In conjunction with the late bishop of London he published *Ricardi Porsoni Adversaria* (1812), and excellent editions of the *Alcestis* and *Hippolytus* of Euripides.

MONKEY, the common name of the family *Simiada* of the order *quadrumana*. The teeth are 32 to 36 in number, and more or less approximate; the canines are larger than the incisors, the upper ones separated by a considerable interval from the latter; the face denuded; the fore feet often larger than the hind, and the middle finger of both hands and feet the largest; opposable thumbs on fore and hind limbs, chiefly formed for grasping; mammae pectoral, 2 or 4; stomach simple. Their food consists of vegetables and insects. Their habits are generally arboreal, and their habitats the forests of tropical America, Asia, and Africa. The monkeys of the new world are entirely distinct from those of the old; the former have been called *simia platyrrhini*, or broad-nosed monkeys, and the latter *simia catarrhini*, or narrow-nosed monkeys.—The *platyrrhini* have the nostrils wide apart, on the sides of the nose as it were; they have no cheek pouches nor callosities on the rump, and their long tails are generally prehensile; the hands have either 4 or 5 fingers, the first or thumbs very slightly if at all opposable; the teeth are: incisors $\frac{1}{2}$, canines $\frac{1}{2}$ — $\frac{1}{2}$, molars $\frac{3}{4}$ — $\frac{3}{4}$ = 36; they inhabit the warm parts of South America. The marmosets have been described under that title, and the remainder of the tribe may be divided into howlers and sapajous. The howling monkeys belong to the genus *myctes* (Illiger), and are characterized by a pyramidal head, bearded face, pentadactylous hands and feet, and tail naked at the end on the lower surface; the lower jaw is very

high, and the hyoid bone is expanded into a kind of drum, which renders the voice so resonant and loud that their troops make a most frightful noise during the night, leading the traveller to think that all the wild beasts of the forest are engaged in fighting for their prey; they are the largest and fiercest of the American monkeys, resembling the baboons in disposition and facial angle, and the gibbons (*hylobates*) in their noisy and gregarious habits. The species are most abundant in Guiana and Brazil, where 80 or 40 are often seen on a single tree. The brown howler or araguato (*M. ursinus*, Humb.) is reddish brown, with long hair and beard, and bluish black face; it is nearly 8 feet long, exclusive of the tail. The red howler (*M. seniculus*, Ill.) has a redder tinge to the hair, with black face, and nearly bare under parts. There are several other species. The sapajous are more slender in form, with flatter faces, longer tails, and milder dispositions than the howlers, resembling the guenons or long-tailed monkeys of the old world. In the genus *ateles* (Geoffroy), the head is rounded, the limbs very long and slender, the fore hands without thumbs, or with very rudimentary ones, and the tail long and prehensile and bare at the tip beneath. The coaita (*A. paniscus*, Geoffr.) is entirely black; they are timid, mild animals, rather sluggish when not excited, but exceedingly agile among the trees; as they swing from the branches by their tails they look not unlike large black spiders, and are commonly called spider monkeys; the tail is not only a 5th hand for purposes of progression, but an exquisite organ of touch. There are several species, which live in troops on the banks of the Amazon and Orinoco. *Lagothrix* (Geoffr.) differs from the last chiefly in the hands having a thumb and in the greater fineness of the hair; the *L. Humboldtii* (Geoffr.) is of a grayish black color, about 2 feet long, with the prehensile tail longer than the body. In the genus *cebus* (Geoffr.) the head is rounded, and the long tail is hairy throughout and prehensile; the monkeys of this genus are very active, excellent climbers, with well formed hands; the size is small, the disposition mild and playful, and the habits gregarious. The horned sapajou (*C. fatuellus*, Geoffr.) is blackish brown, with the face surrounded with whitish, and the hair of the forehead rising in 2 lengthened tufts above the eyes. The capuchin monkey (*C. capucinus*, Erxl.) varies from grayish white to olive, with a black crown like a monk's cap. The weeper monkey (*C. apella*, Geoffr.), so called from its plaintive cry, is deep brown above, with darker feet, crown, and tail, and lighter around the face. The white-throated sapajou (*C. hypoleucus*, Geoffr.) is black, with the front and sides of the head, throat, and shoulders white; it exhales an odor of musk. There are several other species, all lively and mild in disposition, inhabiting Guiana. In the genera hitherto alluded to, the nails are flattened and rounded; in the next three they more resemble claws, and

the animals included in them have more carnivorous propensities, eating meat, insects, and small birds which they seize. In *callithrix* (Geoffr.), of which the type is the siamiri or squirrel monkey (*C. sciureus*, Geoffr.), the ears are proportionately large, the body slender, the tail longer than the body, entirely hairy, and not prehensile; the color is grayish brown, lighter beneath, with reddish limbs and black muzzle; the body is 7 or 8 inches long, and the tail 10 or 12. Other species are described, all active and beautiful animals, with carnivorous propensities; they inhabit principally Brazil and Guiana. In *aotes* (Humboldt) the 2 middle upper incisors are broad, and the canines moderate; the eyes large; hind feet longest; tail longer than the body, not prehensile; nocturnal in its habits, living in pairs, resembling the lemurs of S. Africa. The douroucouli (*A. trivirgatus*, Humb.) is covered with a soft grayish white fur, with a dorsal brown line, 3 dark stripes on the head, and is yellowish brown below; it looks more like a cat than a monkey, and the mouth is surrounded by bristly white hairs; the body is about 9 inches and the tail 14; it sleeps during the day, and is active at night; the position when seated is like that of a dog, and when sleeping the head is bent forward between the feet; it is difficult to tame, and its voice is loud and disagreeable. The last genus which need be mentioned of the American monkeys is *pithecia* (Desm.), characterized by a round head, short muzzle, long canines, tail generally shorter than the body, entirely hairy, and not prehensile; they are nocturnal and gregarious, greatly resembling human pigmies, and said to be active, strong, and almost untamable. The couxiu or black saki (*P. satanas*, Humb.) is dusky black, with a purplish tinge beneath, and with the tail is about 2½ feet long. The monk saki (*P. chiropotes*, Humb.) is brownish red, and of all the American species bears the closest resemblance in its features to man; the expression of the face is fierce and melancholy, the chin is covered with a thick beard, and the eyes are large and sunken; it is said to drink from the hollow of the hand, and to be very careful not to wet its beard. The cacajao or black-headed saki (*P. melanocephala*, Desm.) is about a foot long; the color of the body is yellowish brown, with the head black; there is no beard, and the tail is so short that Spix has placed it in a new genus *brachyurus*; it is weak, inactive, and very timid. The yarke (*P. leucocephala*, Audeb.) is black with the head whitish; the hair is very long. These and several other species inhabit the woods of Guiana in troops, where they are generally called night or fox-tailed apes.—Of the old world monkeys, or *catarrhini*, the largest have been mentioned in the articles APE, BABOON, CHIMPANZEE, GORILLA, and MACAQUE; so that it only remains to notice the smaller and long-tailed species. This division of the monkeys has the same number of teeth as man, viz., 32, and similarly arranged, except that the

incisors are more prominent, and the canines larger and separated from the incisors; there is a thin septum between the nostrils, hard naked skin or callosities on the rump, pouches on the sides of the face between the cheeks and the jaws; they generally have tails, though these are absent in the larger anthropoid apes; they are found in the warmer parts of Asia and Africa, only one species being naturalized in Europe (the Barbary ape on the rock of Gibraltar). The first of the monkeys not already noticed, connecting the guenons or long-tailed monkeys with the gibbons or long-armed apes, is the *presbytis* or capped monkey; this has no cheek pouches, but has naked callosities, a long tail, and arms reaching to the knees. The *P. mitrula* (Eschsch.) has the body 1½ feet long, and the tail about as long; the hair is bluish gray above and grayish white below, with a black line from the ears across the head; it is a native of Sumatra. In the African genus *colobus* (Ill.) there are no thumbs on the hands, and the limbs are long and slender as in the spider monkeys (*ateles*) of the new world. The king monkey (*C. polycomus*, Geoffr.) is remarkable for the long, coarse, and flowing hair on the head, like a full-bottomed periwig; the body is shining black, and the tail is pure white. Other species are described, all natives of Guinea and Sierra Leone. The proboscis monkey (*nasalis larvatus*, Geoffr.) has a short muzzle, but the nose is lengthened into a kind of proboscis 4 inches long, at the end of which the nostrils are placed; the body is thick and the limbs stout; there are cheek pouches and callosities, and the tail is longer than the body; the color is reddish brown, with lighter patches on the lower back, and the face black; the body is about 2½ feet long; they are very active and noisy, and inhabit in large troops the forests of Borneo. The Cochin China monkey, or douc (*lasiohyga nemae*, Ill.), is a very singularly marked species; the muzzle is slightly elongated, the face bare, the hands longer than the forearm with short and slender thumbs; it has cheek pouches, but no callosities, and the tail is long. The colors are brilliant, the upper part of the head being brown with a chestnut frontal band, long hair of cheeks dirty white, forearms and tail white, the hands and thighs black, legs chestnut, and body olive gray; it stands nearly 4 feet high. The first genus of the guenons is *semnopithecus* (F. Cuv.), with round head, flat nose, long limbs, short thumbs, small cheek pouches and callosities, slender form, very long and thin tail, and canines much longer than the incisors; they inhabit India and its archipelago. The *S. entellus* (F. Cuv.) has a body about 1½ feet long and the tail 2 feet; the hind limbs are much longer than the anterior; the color is yellowish white, paler beneath, with the face, forearms and hands, knees and feet, black; it appears slow, sad, and stupid when at rest, but when roused is extremely active; it is very sensitive to cold, and is therefore rarely seen in menageries. It is called

hoonuman by the Hindoos, and so venerated by them that it is considered a crime to kill one; it is believed that the person who should destroy one will surely die within the year; it occupies a conspicuous place among their divinities. The negro monkey (*S. maurus*, Horsf.) has soft and silky hair of a general black color, the lower parts, inner side of limbs, and base of tail grayish; the body is about 2½ feet long and the tail nearly as much, and the proportions are robust. They are numerous in the forests of Java, and are hunted by the natives, who use the fur for various decorative purposes. There are several other species in Sumatra. The genus *cercopithecus* (Ersl.) differs from the last in the larger facial angle, more elegant shape and coloring, longer posterior limbs, and milder and more affectionate disposition; it has only 4 tubercles to the last lower molar, instead of 5 as in *semnopithecus*. The varied monkey (*C. mona*, Geoffr.) is the handsomest of all; the body is chestnut, upper part of head bright yellowish green, cheeks yellow, outside of limbs and tail blackish, with a spot of white on the nates; it is a native of Africa, cunning, active, intelligent, and playful. The Diana monkey (*C. Diana*, Geoffr.) is so called from the white crescent on the forehead; the chin and throat are white; it is about 1½ feet long with a tail of 2 feet. The golden guenon (*C. auratus*, Geoffr.), from Asia, is golden yellow above, paler below, with a black spot on the knee. There are many other species, most, like the first two, from Africa. The mangabeys (*cercopithecus*, Geoffr.) begin to come near the baboons in the more lengthened muzzle and receding forehead, though they have the long tail of the guenons; they are found in Africa and India. The green monkey (*C. sabaeus*, Geoffr.) is a native of Africa and the Cape Verd islands, and is very often seen in captivity on account of its lively and playful manners; the color is olive green above, shading into white below, and the face is black. The malbrouck of Bengal (*C. cynomorus*, Geoffr.) is olive brown above, shading into white, with a white band over the eyes; it is an excellent climber and very active, and is often seen in menageries. The white-eyed mangabey (*C. fuliginosus*, Geoffr.) is of a sooty black color, with white and very conspicuous upper eyelids; it is a native of Africa. These and the numerous other species of Asia and Africa are generally easily domesticated when young; they are good-natured, playful, and free from the disgusting habits of the larger baboons.—The restriction of the *catarrhini* to the old and of the *platyrrhini* to the new world prevailed in the tertiary geological epochs. Fragments of a jaw and some teeth found in the eocene sand of Suffolk, England, were referred by Owen to the genus *macacus* under the name of *M. eocenus*; this furnishes a remarkable proof of the former more elevated temperature of Europe, monkeys having lived during the eocene period 15° further N. than at the present time. In the miocene of France, in lat. 43° N.,

were found portions of a jaw and teeth, very anthropoid in appearance, belonging to what De Blainville has called *pithecus antiquus*, which some have thought nearer to man than is the chimpanzee. Other fragments have been found in England, Greece, and France, which have been referred to the genera *macacus*, *pithecus*, and *semnopithecus*. In the Sivalik hills of India have been discovered specimens of *semnopithecus* nearly as large as the orangs, and some resembling baboons. In South America, M. Lund found in Brazil, in lat. 18° S., specimens which he referred to the genera *cebus*, *callithrix*, *primæus* (twice the size of any living species), and *protopithecus Brasiliensis*, which must have attained a height of 4 feet; he also found there *omistitis* (*J. grandis*) twice as large as any now living.

MONMOUTH, a central co. of N. J., bordering on the Atlantic ocean, drained by the Neversink, Shrewsbury, Shark, and Tom's rivers; area, about 800 sq. m.; pop. in 1855, 84,978. Its surface is generally level, with elevations toward the N. E. The productions in 1850 were 841,072 bushels of Indian corn, 152,904 of wheat, 778,272 of potatoes, 158,546 of oats, and 31,548 lbs. of wool. There were 82 grist mills, 20 saw mills, 4 woollen factories, 14 tanneries, 14 distilleries, 6 newspaper offices, 60 churches, and 6,029 pupils attending public schools. A railroad is in operation between Port Monmouth and Long Branch; and a branch railroad connects the capital, Freehold, with the Camden and Amboy railroad at Jamesburg.

MONMOUTH, BATTLE OF, an encounter between the American and British forces, the former commanded by Gen. Washington and the latter by Sir Henry Clinton, which took place at Freehold, Monmouth co., N. J., June 28, 1778. On June 18 Sir Henry Clinton, acting under peremptory orders from the British ministry, evacuated Philadelphia, which had been occupied by his army since the preceding September, and proceeded across New Jersey toward Brunswick, with a view of embarking on the Raritan. On hearing of this movement, Washington broke up his camp at Valley Forge, and, having sent forward some light troops to harass the enemy, started in pursuit. Owing to excessive heat the march of both armies was slow, and the British were moreover encumbered by a baggage train 12 miles in length. At Allentown Clinton suddenly turned to the right by a road leading through Freehold to Sandy Hook, to embark at the latter place; and Washington, who had hitherto been deterred by the advice of his officers, and particularly of Gen. Charles Lee, from attacking the enemy, determined at once to give him battle. The evening of the 27th found the main body of the enemy encamped on high ground near Monmouth court house in the town of Freehold, while the American advance, about 4,000 strong, under Lee, was posted at Englishtown, 5 miles distant, with the main body about 3 miles in the rear. The command of the advance had

originally been given to Lafayette, with the consent of Lee; but the latter subsequently applied for and obtained it. Early on the 28th Lee engaged the rear division of the enemy, his orders being to hold it in check until the main body under Washington could come up. The Americans were at first successful, but owing to causes which have never been satisfactorily explained, the whole body soon after fell into a confusion in which their commander seemed to participate, and commenced a disorderly retreat, closely followed by the British. Washington, who was advancing hastily with the main body, received the first intimation of this movement in the crowds of fugitives who poured along the road. Exasperated beyond measure at the failure of Lee to execute his orders or to apprise him of his retreat, he rode up to that general and reprimanded him with a vehemence which surprised those accustomed to the habitual self-control of the commander-in-chief. Then, rallying by his voice and presence the fugitives, he re-formed them on a piece of rising ground, and hastened back to bring up the main body. Lee, resuming his command, held his position with spirit until compelled to retire, and brought off his troops in good order. The main body, which had meanwhile taken a favorable position on an eminence, with a morass in front and a wood in the rear, opened an effective cannonade from both wings upon the British. The latter, after an ineffectual attempt to turn the American left under Lord Stirling, directed their chief efforts against the right commanded by Greene, where Wayne, under cover of an orchard, was harassing their centre by a severe fire. To dislodge him, Col. Moncton advanced with a column of royal grenadiers, but fell at the head of his troops, who were repulsed with considerable loss. The enemy at length fell back to the ground occupied by Lee in the morning, whither Washington was preparing to follow them when the approach of night and the exhaustion of his men induced him to defer the execution of his plan until the morning. During the night Clinton effected a noiseless retreat, and at daybreak was many miles away from the scene of battle. The excessive heat of the weather and the fatigued condition of the troops rendered a pursuit impracticable, and the royal army was suffered to proceed unmolested to the place of embarkation. The American loss in this engagement was 69 killed and 160 wounded; that of the British probably nearly 800 killed and 100 prisoners including wounded. Their total loss by desertions and the casualties of battle during their march through New Jersey has been estimated at 2,000. On both sides many men died from the effects of the heat alone. For his conduct in this battle Lee was court-martialled and suspended for one year from his command.

MONMOUTH, a market town and municipal and parliamentary borough of England, capital of Monmouthshire, situated in a picturesque valley at the confluence of the Wye and Mon-

now, 129 m. N. W. from London; pop. in 1851, 5,710. The Wye fisheries in the vicinity are flourishing. The borough, in conjunction with Newport and Usk, sends one member to parliament. Henry V. (Harry of Monmouth) and Geoffrey the chronicler were natives of this town. The battle of Monmouth, in which Owen Glendower was defeated by Henry, prince of Wales, was fought May 11, 1405.

MONMOUTH, GEOFFREY OF. See **GEOFFREY**.

MONMOUTH, JAMES SCOTT, duke of, a supposed son of Charles II., king of Great Britain, born in Rotterdam, April 9, 1649, executed in London, July 15, 1685. His mother was Lucy Walters, daughter of a gentleman of Pembroke-shire. She was first the mistress of Algernon Sidney, who was then a colonel in the parliamentary army, and next of his brother, Col. Robert Sidney, with whom she became acquainted in Holland. Robert Sidney was by some reputed the father of Monmouth. Charles was then in Holland, and Lucy Walters became his mistress. He acknowledged her son to be his offspring, and was throughout life strongly attached to him. The boy was known as James Crofta, because he was for some time in the charge of Lord Crofta, and passed for his relative. When he was taken to England, in 1662, he was very accomplished and very handsome. The king treated him as kindly as if he had been his legitimate son. He was first made duke of Orkney, but the title was changed to that of Monmouth. He was also created baron of Tyndale and earl of Doncaster at the same time, Feb. 19, 1668; and on March 28, 1668, he was elected a member of the order of the garter. Oxford and Cambridge conferred on him the degree of A.M. He served on board the fleet of the duke of York in 1665, and was in the battle of Lowestoffe, June 8. In 1667 he was married to Anne Scott, daughter and sole heir of Francis Scott, earl of Buccleugh. He and his wife were created duke and duchess of Buccleugh, earl and countess of Dalkeith, and baron and baroness of Whitcheater and Ashdale in Scotland, in 1673. He was made master of the horse about the date of his marriage, and captain of the horse life guards in 1668; and on the death of the duke of Albemarle, in 1670, he succeeded him as captain-general of all the king's fortresses. He became a privy councillor the same year. He was allowed privileges at court which could be claimed only by persons of the blood royal. The people, who loved him because of his amiability, bravery, and personal beauty, were led to believe him the king's legitimate son. They forgave him the part he had in the licentiousness of the period, and also when he caused Sir John Coventry to be brutally mutilated for having spoken severely of the king's conduct in parliament. At first, Monmouth and his uncle, the duke of York, were friends, but they soon became rivals in love and politics. Those persons who dreaded the accession of York to the throne (the king having no legitimate children, nor expecting

any) endeavored to have Monmouth recognized as heir presumptive; and they hinted to Charles II. that it would not be difficult to have his marriage with Lucy Walters proved by competent false witnesses; but the king promptly replied that, "much as he loved the duke, he had rather see him hanged at Tyburn than crown him for his legitimate son." When England joined France in the war against Holland, Monmouth was sent at the head of 6,000 troops to act under Louis XIV. in 1672. He served in two campaigns with considerable distinction, and was made a lieutenant-general by the French king, who gave him a splendid sword. In 1674 he was elected chancellor of the university of Cambridge. When England changed her policy, and joined the Dutch, Monmouth was continued in his position as lord-general of the king's forces in Flanders, and took part in the battle of St. Denis. He had been made commander-in-chief of the armies of England and Scotland, and was known as "the Protestant duke." On the breaking out of the delusion known as the popish plot, he was among its encouragers, and his designs on the succession to the throne were much favored by Shaftesbury and his associates, and by the extreme unpopularity of the duke of York, heir presumptive, who was a Catholic, and who was compelled to leave the country. On the revolt of the Scotch Covenanters in 1679, Monmouth was sent to act against their forces, and defeated them, June 22, at Bothwell Brig. As he treated the rebels mildly, and would willingly have spared them all, he was accused of favoring rebellion. His entire conduct in Scotland was statesmanlike, and in strong contrast with that of Lauderdale and Claverhouse. Monmouth was compelled to resign his office of lord-general, and to go to Holland. Thence he returned to England without leave, and upon his refusal to quit the kingdom his offices were taken from him. He now became the principal person of the opposition to the court, and his pretensions to the crown were vigorously but not wisely pressed by his followers, rather on a popular than on a legal basis; but when the duke of York returned to court, the story of the marriage of Charles II. and Lucy Walters was gravely urged, and the king deemed it necessary to deny it in the most public and formal manner. The part he had in the conspiracies of 1688 led to his flight to Holland, after considerable negotiation with the king for pardon. He was well received at the Hague, and was in expectation of an early recall to England, and a full restoration to the king's favor, when Charles II. died, Feb. 6, 1685. He left the Hague, but instead of following the wise counsel of the prince of Orange, which was to enter the imperial service, he allowed himself to be deluded by the suggestions of British exiles, and placed himself at the head of a small expedition, which left Holland, and arrived at Lyme Regis, June 11, 1685. At first the duke met with some success; but being joined only by persons from the lower

ranks, and the government acting with great energy, his forces were beaten at Sedgemoor, July 6, and on the 8th he was captured and taken to London, where he had an interview with James II., of whom he begged his life in abject terms; but the king refused his request, and he was executed under an act of attainder two days after his arrival in the capital. His followers continued to believe that he was alive for many years, and it was supposed by some that he was the man with the iron mask who was so long a prisoner in the Bastille. His wife, a woman of superior talents, from whom he had been separated, survived him nearly 47 years, and married Charles, third Lord Cornwallis. Monmouth is the Absalom of Dryden's "Absalom and Achitophel."

MONMOUTHSHIRE, a maritime county of England, bounded S. by the Bristol channel and the estuary of the Severn; area, 576 sq. m.; pop. in 1851, 157,418. The coast, which is 22 m. in extent, is exposed to the high spring tides that rush up the Severn from the Bristol channel, and sometimes attain an altitude of 60 feet. Vast sea walls and earth works have been erected. The surface toward the N. is mountainous and rocky; adjoining the Severn and the sea is a spacious plain, which the river Usk divides into two parts, called the Wentloog and Caldecot levels. The principal mountains are: Penny-Val, or the Sugar Loaf, 1,856 feet high; Blawrenge mountain, 1,720 feet; and Skerryd Vawr, or Holy mountain, 1,498 feet. The chief rivers are the Wye, Usk, and Monnow, the two former of which are famous for their salmon. The soil of the vales and plains is generally fertile. Iron, coal, lead, and building stone are produced. The average proportion of iron yielded by the ore is from 18 to 55 per cent. The principal iron works are the Rumney, Tredegar, Victoria, Pentwyn, and Beaufort. The iron and coal of this county are almost entirely shipped at Newport. The area of its mineral districts is estimated at 89,000 acres. The county returns 2 members to parliament. Chief towns, Monmouth, the capital, Newport, Abergavenny, and Chepstow. Monmouthshire was originally a part of South Wales, and the Welsh language is still largely in use there.

MONOD, JEAN, a French Protestant clergyman, born in Switzerland about 1760, died in Paris in 1836. He was descended from a family of Huguenots, and officiated as pastor of the Reformed church in Paris until the outbreak of the first revolution, when he removed to Copenhagen, where he became the pastor of a small church, and where he married. While in Copenhagen the duke of Orleans, the future king Louis Philippe, enjoyed his hospitality, and afterward welcomed him to Paris, Monod having been repeatedly delegated by the Protestants of Paris to present the annual congratulations to the king. His widow, who was a woman remarkable for her intelligence and force of character, died in 1851.—FRÉDÉRIC, D.D., eldest

son of the preceding, born near Morges, Switzerland, May 17, 1794, received his theological education at Geneva, and after the death of his father became pastor of the Oratoire in Paris. From his ability as a preacher and his high character, he was regarded as a leader among the evangelical Protestants of France. After having officiated in the Oratoire for upward of 20 years, he seceded from the national Protestant church, April 22, 1849, not because it was recognized by the state, but because it did not insist upon "the acknowledgment of Christ as a divine Saviour" as a condition of membership. In his farewell sermon he says: "Whatever may be written or said to the contrary, I retire upon this ground, and not upon the question of a separation of church and state, nor any question of ecclesiastical discipline, nor any minor consideration whatever." In thus breaking off from the church Dr. Monod sacrificed a position of comparative affluence, honor, and influence. In conjunction with a small but influential body of evangelical Christians, he immediately set about the organization of the free church of France, resembling in some respects the free church movement in Scotland. In 1858 he visited the United States in order to enlist the sympathies of Americans in the movement. He is the editor of the *Archives du Christianisme*. He has a large family, and two of his sons are in the ministry. One of them studied theology at the Presbyterian (O. S.) seminary at Alleghany City, Penn., and afterward officiated as preacher in St. Anne, Kankakee co., Ill.—ADOLPHE, a brother of the preceding, born Jan. 21, 1802, died in Paris in 1856. He was also educated at Geneva, and held to the same views in regard to the divinity of the Saviour as his brother Frédéric, yet remained in the national church. In early life he became one of the pastors of the Reformed church in Lyons, whence he was dismissed in consequence of his rigid adherence to evangelical principles. He was afterward professor in the theological school at Montauban, and in 1849, on the secession of his brother from the national church, he was invited to fill his place at the Oratoire, with Athanèse Coquerel as his colleague. He held this position until his death, and gained a high reputation for pulpit eloquence. He is the author of "Lucille," "Woman's Mission," "Sermons," and other works, several of which have been translated into English.—GUILLAUME and HORACE, brothers of the preceding, are also favorably known in the French Protestant world. The former was pastor in Switzerland, in France, and in Algeria; and the latter has been for a long time established as pastor in Marseilles.

MONOGRAM (Gr. *μονος*, single, and *γραμμα*, letter), a character or cipher, formed by interweaving the initials or other letters of a name. Monograms were common in antiquity, especially on the coins of the Greeks. They came into general use in the countries subject to Charlemagne, not only on the coins, but the ecclesiastical and temporal lords chose each a monogram

for their signature. The explanation of modern monograms is important in the criticism of historical monuments and documents, and forms a special branch of diplomacy. An example of oriental monograms is the *theogra*, a figure on the coins of Turkey, in which the imperial name and insignia are obscurely involved. The signature which painters, engravers, and other artists inscribe upon their works is usually a monogram. The monogram of Christ, with which paintings, coins, tombs, precious stones, seals, rings, and ecclesiastical documents were adorned in the middle ages, is formed from the first two Greek letters of the name, X and P, the

✠ It may be traced to the age of Antonine Pius, and precisely the same conjunction of the letters appears on heathen monuments previous to the Christian era. With the monogram very often combined the letters alpha and omega to indicate that Christ was the beginning and end of all things. Abbreviations of his name and titles were also employed, as I. H. S., *Iesus hominum Salvator*. A mystical word or figure was often used instead of the monogram, a *Ixthyr* (a fish), formed from the initials of *Iesous Xristos Theou Yios Soter*. The figure of the cross sometimes took the place of the name.—Baudis, *Ad Analysis Monogrammatum* (Lipsic, 1787); Brulliot, *Dictionnaire des monogrammes* (new ed., 1832-'4); and Birtner, *Die vorzüglichsten Denkmäner der katholischen Kirche* (7 vols., Mentz, 1835-'45).

MONOMANIA. See **INSANITY**.

MONONA, a W. co. of Iowa, separated from Nebraska by the Missouri river, and intersected by the Little Sioux; area, about 900 sq. m. pop. in 1859, 885. It is covered with prairie and has a fertile soil. The productions in 1859 were 43,445 bushels of Indian corn, 1,544 of wheat, 2,536 of oats, 5,113 of potatoes, 1,122 tons of hay, and 18,771 lbs. of butter.

MONONGAHELA RIVER, one of the best branches of the Ohio, formed by the union of the West fork and Tygart's Valley river in Mingo co., Va., flows N. into Pennsylvania, where it receives the Cheat river, its principal tributary, and unites with the Alleghany to form the Ohio at Pittsburg; length, exclusive of branches, about 150 m., or including the Tygart's Valley river or East fork (which rises in Randolph co., Va.) 300 m. At its mouth the width is nearly 500 yards. It is navigable for large boats to Brownsville, Penn., 60 m. from its mouth, and for small boats to Fairmont, Va., at its head.

MONONGALIA, a N. W. co. of Va., bordering on Penn., and intersected by Monongahela and Cheat rivers; area, about 500 sq. m. pop. in 1850, 12,887, of whom 176 were slaves. The surface is uneven, being mountainous toward the E., where it is crossed by Letcher hill, an extreme western ridge of the Alleghanians; the soil is generally fertile. The productions in 1850 were 184,879 bushels of Indian corn, 111,252 of oats, 52,370 of wheat, 29,129 lbs. of wool, and 3,750 of tobacco.

There were 25 grist mills, 17 saw mills, 2 iron founderies, 3 furnaces, 81 churches, and 548 pupils attending public schools. Value of real estate in 1856, \$2,997,075, showing an increase of 25 per cent. over 1850. Capital, Morgantown.

MONOPHYSITES (Gr. *μονος*, single, and *φύσις*, nature), a sect who rejected the doctrinal decision of the council of Chalcedon (451), that there are in the one person of Christ two natures without confusion, but inseparably united, and maintained in opposition to it that there is in Christ only one nature, the divine one, which has become flesh. The forerunner of this sect was Eutyches, who maintained that every thing human in the nature of Christ was absorbed by his divinity and became one nature with it. This doctrine of Eutyches was condemned by a synod of Constantinople, held under Bishop Flavianus in 448, approved in the following year by the so called robber synod of Ephesus under the presidency of the patriarch Dioscurus of Alexandria, but in 451 again anathematized by the œcumenical council of Chalcedon. An Alexandrian monk, Theodosius, who had been present at the council of Chalcedon, induced about 10,000 monks of Palestine to refuse submission to the decrees of the council. They were willing to reject Eutychianism, but at the same time opposed the Chalcedonian doctrine, as inevitably leading to Nestorianism. They received from their opponents the name Monophysites, while they in turn called the adherents of Chalcedon Nestorians or Diophysites. The Monophysites soon took possession of the patriarchate of Jerusalem, but the emperor restored it to the Catholic party in 458. In Egypt, where 13 bishops had protested from the beginning against the Chalcedonian decrees, the Chalcedonian patriarch was murdered in a tumult, and Timotheus Melus, a Monophysite, appointed in his stead (457). In Antioch a leader of the Monophysites was raised to the patriarchal dignity after the Chalcedonian patriarch had been prevailed upon to resign. The usurper Basiliscus (476) patronized the Monophysites, but after his defeat (477) the Catholic party again gained the ascendancy. The emperor Zeno, following the advice of the patriarch Acacius of Constantinople, made an attempt to reconcile the parties by means of a creed called *Henoticon* (482), which entirely avoided the disputed articles; but this scheme found opponents among both parties. Felix II., the bishop of Rome, excommunicated Acacius as its author, and the extreme Monophysites in Egypt broke off ecclesiastical communion with the patriarch Peter Mongus, who had accepted the *Henoticon*. Justin I., and still more decidedly Justinian, employed severe measures for the suppression of Monophysitism, which found, on the other hand, an ardent supporter in Theodora, the wife of Justinian, who even made (538) an unsuccessful effort to fill the see of Rome with a Monophysite. Previously (533) Justinian had tried in vain to effect a union by allowing the Monophysites to use their formula

that one of the Trinity was crucified. When the Monophysites invoked for their support the authority of Origen, the Catholic party procured from the emperor the condemnation of his writings. Monophysites, on the other hand, induced the emperor to condemn the teachings of three of their chief opponents, of the Antiochian school, and thus to throw an apple of discord among the Chalcedonian party. An œcumenical council, convoked by the emperor at Constantinople in 553, confirmed the condemnation of Monophysitism on the one hand, and of the "three chapters," the epitome of the doctrines of the three Antiochian teachers, on the other. The Monophysites, in the meanwhile, had fallen out among themselves; some (the Severians) maintaining the corruptibility, others (the Julianists) the incorruptibility of the body of Christ. By adopting the latter doctrine Justinian made (in 564) a last attempt to draw over the Monophysites, but with no other result than to cause a new split among the Catholic bishops. Under his successor the efforts to make the Monophysites accept the decrees of Chalcedon were given up, and they organized as an independent body. The zeal of Jacobus Baradaeus, who in 541 was ordained bishop of Edessa, gave them in Syria and Mesopotamia a permanent organization with a patriarch, claiming to be the legitimate successor of the Antiochian patriarch, at their head. They also received from him the name Jacobites, by which they were henceforth commonly called. (See *JACOBITES*.) As early as 527, the bishops of Armenia rejected at a national synod, under the presidency of their patriarch Nerses, the decrees of Chalcedon, and organized, on a Monophysitic basis, an independent church. (See *ARMENIAN CHURCH*.) In Egypt nearly all the churches adopted Monophysitism; the few adherents of the imperial decrees were called Melchites (*i. e.*, royalists), while the Monophysites received the name of Coptic (*i. e.*, Egyptian) Christians. (See *COPPS*.) With this latter branch of Monophysitism, the Abyssinian church is in organic connection. Some smaller branches of these four Monophysitic churches spread in other parts of western and in central Asia, without, however, obtaining any importance.—The history of the Monophysites is most amply treated of by Walch, in his *Ketzehistorie*, vol. vi., vii., and viii. An extensive extract from this work is given in Schröckh's *Kirchengeschichte*, vol. xviii. Writings and fragments of the party leaders are contained in Mai's *Scriptorum Veterum Nova Collectio*, vol. vii. (Rome, 1838), and *Spicilegium Romanum*, vol. vii.

MONOTHELITES (Gr. *μονος*, single, and *θέλας*, to will), the name of a sect which accepted, in accordance with the council of Chalcedon, the doctrine of two natures in the person of Christ, but maintained that there was but one manifestation of will. The emperor Heraclius, following the advice of the patriarchs Cyrus of Alexandria and Sergius of Constantinople, hoped, by means of a formula expressing these views,

to reunite the Monophysites with the orthodox church. The attempt proved partly successful; but the resolute opposition of the patriarch Sophronius of Jerusalem reopened the controversy on the person of Christ throughout the church. An imperial edict, *Ekthesis* (639), composed by Sergius, patriarch of Constantinople, and approved by Pope Honorius, which proclaimed that there was but one Christ and but one will, seemed to secure the ascendancy of the Monothelites. But after the death of Honorius, the bishops of Rome placed themselves at the head of the opposition, and a new decree of the emperor Constans II., called *Typus* (648), designed to enforce peace by a prohibition of the controversy, had not the desired effect. The first council of Lateran (649) under Pope Martin I. condemned the Monothelites and the two imperial laws. The pope suffered imprisonment for this decree, but some years later (680) the sixth œcumenical council, held at Constantinople, recognized in Christ two wills made one by the moral subordination of the human, excommunicated Macarius, patriarch of Constantinople, and other leaders of the party, and "anathematized the former pope Honorius, because he had shared the impious opinions of the patriarch Sergius of Constantinople." The Monothelites obtained once more a transient victory under Philip Bardanes (711-713), who had been brought up by the patriarch Macarius; but after the elevation of Anastasius II. to the throne, all the Monothelites were forced to submit, and the sect maintained itself only in a corner of Asia, outside of the Byzantine boundaries, until the 12th century, when they united with the Roman Catholic church. (See MARONITES.)—A *Historia Hæresis Monothelitarum* has been written by Oombefis, in his *Auctuarium Patrum*, vol. ii. (Paris, 1648).

MONOTREMATA (Gr. *monos*, single, and *trēma*, opening), an order of implantal mammals, or those in which the embryo forms no vascular connection with the uterus; the name is derived from the fact that the intestinal, generative, and urinary organs open into a common cloaca, as in birds and reptiles. The order includes the ornithorhynchus and the porcupine ant-eaters (*echidna*), from Australia and Tasmania. They are the lowest mammals, and have many characters of birds and reptiles in their structure and mode of reproduction; they have no abdominal pouch, but the marsupial bones are present; at the top of the breast bone is an episternum with lateral arms forming the chief support of the scapular arch, on the top of which the true clavicles, like the furcular bone of birds, are situated; the coracoid bones extend also to the sternum, and are surmounted by epicoracoid bones; in the scapular arch, therefore, they resemble in some respects birds, in others lizards and enaliosaurians. The eyes are very small, the external ears absent, and the face projects in the form of a naked beak, without teeth or soft movable lips; the teeth are replaced by small horny plates; some au-

thors, as Wagner, have ranked them among edentates. The feet are 5-toed, with long nails; the males have a long spur on the hind leg, the groove of which communicates with a glandular organ, whose secretion has been erroneously supposed to be poisonous; the mammary orifices are mere slits in the skin of the abdomen, without elevated nipples, and the female sexual organs resemble those of birds; the young are born alive, and are suckled as in other mammals; the cæcum is small; the lungs are spongy and cellular, and enclosed in a thoracic cavity separated from the abdomen by a diaphragm; in the brain there is no corpus callosum, and the bigeminal bodies are simple. ORNITHORHYNCHUS, and PORCUPINE ANT-EATER.

MONRO, ALEXANDER, an English physician and anatomist, born in London in 1697, died in Edinburgh, July 10, 1767. He studied at Edinburgh, London, and Leyden, and in 1720 began at Edinburgh, in connection with another young physician named Alston, a course of lectures on anatomy and materia medica, which were the first regular lectures on the medical sciences that had ever been delivered in that city. On the foundation of the Edinburgh faculty of medicine in 1721, Dr. Monro was appointed professor of anatomy, but was not inducted into office till 1725. The royal infirmary of Edinburgh was founded under his direction, and he lectured there on surgical science till 1759, when he resigned his lectureship to his son. His most important work is "Osteology, or a Treatise on the Anatomy of the Bones" (1726), which has been translated into many foreign languages. Some of his contributions to scientific journals were reprinted under the titles "Medical Essays and Observations" and "Essays Physical and Literary." A collective edition of his works, with a memoir by his son, was published at Edinburgh in 1781.

MONROE, the name of 16 counties in the United States. I. A N. W. co. of N. Y., bounded N. by Lake Ontario, and drained by the Genesee river; area, 682 sq. m.; pop. in 1850, 96,324. The surface is generally level, with a slight inclination toward the lake. The soil is very fertile, and agriculture is the leading pursuit. The productions in 1855 were 2,635,000 bushels of wheat, 654,551 of potatoes, 50,000 tons of hay, 1,643,515 lbs. of butter, and 131,200 lbs. of cheese. The New York central, Rochester, Lockport, and Niagara Falls, Rochester and Charlotte, and the Auburn and Canandaigua railroads meet at Rochester, the capital. II. An E. co. of Penn., separated from the E. from New Jersey by the Delaware river, and drained by Tobyhanna and Broad creeks; area, 600 sq. m.; pop. in 1850, 13,500. The surface in some parts is mountainous, but the soil of the valleys is rich. Limestone and slate are found in the county. The productions in 1850 were 101,829 bushels of Indian corn, 14,620 of wheat, 67,485 of oats, 10,253 tons of hay, and 174,204 lbs. of butter. There were 80 flour and grist mills, 20 saw mills, 11 tanneries, 18 churches, 2 newspaper offices, and

1,199 pupils attending public schools. The Delaware, Lackawanna, and western railroad passes through Stroudsburg, the capital. III. A S. W. co. of Va., drained by Greenbrier and New rivers; area, 450 sq. m.; pop. in 1850, 10,204, of whom 1,061 were slaves. It has an elevated surface, and is bounded on the E. and N. by the main branch of the Alleghanies. It is one of the finest grazing counties in the state. The productions in 1850 were 250,456 bushels of Indian corn, 51,436 of wheat, 97,460 of oats, 1,073 tons of hay, and 175,254 lbs. of butter. There were 4 flour mills, 5 saw mills, 1 woollen factory, 5 tanneries, 27 churches, and 498 pupils attending public schools. Value of real estate in 1856, \$3,272,510, being an increase of 7 per cent. since 1850. Capital, Union. IV. A central co. of Ga., bounded E. by the Ocmulgee river, and drained by several branches; area, 70 sq. m.; pop. in 1859, 15,812, of whom 1,960 were slaves. The surface is diversified, and much of the soil fertile. Gold, iron, granite, and plumbago are found. The productions in 1850 were 15,012 bales of cotton, 724,70 bushels of Indian corn, 108,766 of oats, and 166,584 of sweet potatoes. There were 6 churches, 1 newspaper office, and 750 pupils attending public schools. The Macon and western railroad passes through Forsyth, the capital. V. A S. co. of Fla., forming the W. half of the extremity of the peninsula, bounded W. by the gulf of Mexico, S. W. by the bay of Ponce de Leon, N. by the Caloosahatchee river, and N. E. by Lake Okeechobee; area about 1,500 sq. m.; pop. in 1850, 2,645, of whom 481 were slaves. In the S. part of the county lie the "Thousand Isles," and the Florida Keys are included in it. The surface is mostly flat and marshy, and is partly occupied by the everglades. The orange and the cocoa palm are indigenous. The productions are confined almost entirely to a few sweet potatoes, and most of the population centres at Key West, the capital. VI. A S. W. co. of Ala., drained and bounded on the S. W. by the Alabama river; area, 980 sq. m.; pop. in 1850, 12,013, of whom 1,525 were slaves. The surface is moderately uneven and partly occupied by pine forests. The productions in 1850 were 6,977 bales of cotton, 109,506 bushels of Indian corn, 140,985 of sweet potatoes, and 100,031 lbs. of rice. There were 1 grist and saw mills, 1 turpentine manufactory, 1 tannery, 26 churches, and 282 pupils attending public schools. Capital, Claiborne. VII. A N. E. co. of Miss., bordering on Ala., and intersected by the Tombigbee river; area, 950 sq. m.; pop. in 1850, 21,172, of whom 11,717 were slaves. The surface is a level plain or savanna, with few trees, and covered with rank grass. The soil is a rich, calcareous loam. The productions in 1850 were 17,814 bales of cotton, 901,186 bushels of Indian corn, and 68,860 of sweet potatoes. There were 20 churches, 2 newspaper offices, and 600 pupils attending public schools. The Jackson and great northern railroad passes through Aber-

deen, the capital. VIII. An E. co. of Ark., watered by Cache and White rivers; area, 1,040 sq. m.; pop. in 1854, 2,569, of whom 899 were slaves. The surface is generally level, and occupied by cypress swamps and plantations of cotton and maize. The productions in 1854 were 89,650 bushels of Indian corn, 8,559 of oats, and 1,520 bales of cotton. Capital, Lawrenceville. IX. A S. E. co. of Tenn., bordering on N. C.; area, 500 sq. m.; pop. in 1850, 11,784, of whom 1,188 were slaves. It is drained by Tellico river, an affluent of the Little Tennessee. The Unaka or Smoky mountain lies on the S. E. border of the county. The soil is moderately fertile. The productions in 1850 were 671,167 bushels of Indian corn, 177,519 of oats, 42,499 of wheat, and 72,207 lbs. of butter. There were 16 churches, and 1,969 pupils attending public schools. The East Tennessee and Georgia railroad passes through the county. Capital, Madisonville. X. A S. co. of Ky., bordering on Tenn., and drained by the head streams of Big Barren river, and by the Cumberland river; area, 600 sq. m.; pop. in 1850, 7,756, of whom 881 were slaves. The surface is diversified, and the soil fertile. The productions in 1850 were 384,705 bushels of Indian corn, 12,443 of wheat, 77,151 of oats, and 392,762 lbs. of tobacco. There were 15 churches, and 899 pupils attending public schools. Capital, Tompkinsville. XI. A S. E. co. of Ohio, separated from Virginia by the Ohio river, and drained by Little Muskingum river and by Seneca and Sunfish creeks; area, 420 sq. m.; pop. in 1850, 28,851. The surface is hilly and well timbered. It contains beds of coal and some iron. The productions in 1850 were 617,667 bushels of Indian corn, 148,851 of wheat, 224,800 of oats, 8,681,705 lbs. of tobacco, and 6,798 tons of hay. There were 72 churches, 1 newspaper office, and 5,409 pupils attending public schools. Capital, Woodfield. XII. A S. E. co. of Mich., bordering on Lake Erie and Ohio; area, 540 sq. m.; pop. in 1850, 14,698. Huron river forms its N. W. boundary, and the Raisin river traverses the county. The surface is level and diversified by prairies and woodlands. The valley of Raisin river is celebrated for fertility and beauty. The productions in 1850 were 114,600 bushels of wheat, 198,818 of Indian corn, 78,248 of potatoes, and 18,191 tons of hay. There were 5 churches, 8 newspaper offices, and 8,817 pupils attending public schools. The Michigan central railroad passes through Monroe, the capital. XIII. A S. W. co. of Ind., watered by White river and its branches; area, 420 sq. m.; pop. in 1850, 11,286. The surface is hilly, and the soil fertile. The productions in 1850 were 710,465 bushels of Indian corn, 61,146 of wheat, 92,885 of oats, and 3,078 tons of hay. There were 24 churches, 8 newspaper offices, and 2,489 pupils attending public schools. The New Albany and Salem railroad passes through Bloomington, the capital. XIV. A S. W. co. of Ill., bounded W. by the Mississippi river; area, 360 sq. m.; pop. in 1855, 10,285.

The surface is moderately uneven, and the soil is fertile. In 1850 the productions were 899,250 bushels of Indian corn, 89,856 of wheat, and 58,546 of oats. There were 16 churches, and 759 pupils attending public schools. Capital, Waterloo. XV. A N. E. co. of Mo., watered by Salt river and its branches; area, 744 sq. m.; pop. in 1856, 10,358, of whom 2,382 were slaves. The surface consists in part of rich undulating prairies. The productions in 1850 were 798,145 bushels of Indian corn, 48,669 of wheat, 180,412 of oats, and 629,412 lbs. of tobacco. There were 25 churches, and 1,954 pupils attending public schools. The county abounds in coal, limestone, and freestone. Capital, Paris. XVI. A S. co. of Iowa, drained by several creeks; area, 480 sq. m.; pop. in 1859, 8,877. The surface is diversified and occupied partly by prairies, and the soil is fertile. The productions in 1859 were 265,279 bushels of Indian corn, 9,608 of wheat, 8,508 tons of hay, 98,545 lbs. of butter, and 9,054 galls. of sorghum molasses. Capital, Albia.

MONROE, a city and the capital of Monroe co., Mich., 40 m. S. W. from Detroit, on the Detroit and Toledo railroad, and on each side of the Raisin river, 2 m. above its entrance into Lake Erie, with which it is connected by a ship canal; pop. in 1860, about 5,000. It is the E. terminus of the Michigan southern railroad, and the principal market for the staples of several of the southern counties. It contains a female seminary and collegiate institute, a union school and branches, a fine court house, 10 churches, and manufactories of woollen goods, leather, and flour. It was first settled by the French in 1776; but its settlement and improvement by the Americans began in 1835.

MONROE, JAMES, 5th president of the United States, born in Westmoreland co., Va., April 28, 1758, died in New York, July 4, 1831. His father was Spence Monroe, a planter, descended from Capt. Monroe, an officer in the army of Charles I., who emigrated with other cavaliers to Virginia in 1658. He was first sent to a classical school in Westmoreland, under the direction of the Rev. Mr. Campbell; and at the age of 16 or 17 to William and Mary college. His intention was to practise law, but important public events soon drew him toward another theatre of action. In 1776, at the age of 18, he left college and entered the army as a cadet. Soon afterward he received the commission of lieutenant in the company of Capt. William Washington, and took an active part in the campaign on the Hudson. He was present at the battles of Harlem heights and White Plains, and accompanied Gen. Washington in his retreat through New Jersey. In the attack on Trenton, perceiving that the enemy were endeavoring to erect a battery, to rake the American line, he advanced at the head of a small detachment, drove the artillerymen from their guns, and took possession of the pieces. On this occasion he received a ball in the shoulder, and was promoted to a captaincy. As aide-de-camp to Lord Stirling, with the rank of major, he

served in the campaigns of 1777 and 1778, and distinguished himself in the battles of Brandywine, Germantown, and Monmouth. At the first named battle, he was fighting by the side of Lafayette when the latter was wounded. By accepting the place of aid to Lord Stirling he lost his rank in the regular line, which he was desirous of regaining. This was however impossible, under the circumstances; and in order to retain him in the army, Gen. Washington, who had formed a high opinion of his abilities, recommended the legislature of Virginia to authorize the embodiment of a new regiment, and bestow the command upon Monroe. The regiment was authorized, and Monroe appointed colonel: but such was the exhausted condition of Virginia consequent upon the large drafts previously made upon her by the general cause, that the enterprise was found impracticable. Finding his efforts useless, and all hopes of retaining the army as a commissioned officer at an end, Monroe determined to abandon military life, and return to the study of the law. This he proceeded to do, under the direction of Thomas Jefferson, then governor of the state. When the enemy, however, appeared soon afterward in Virginia, Monroe actively exerted himself in organizing the militia of the lower counties. The enemy, who had confined their attack to the seaboard, soon proceeded further southward, and Monroe's services were put in requisition by Gov. Jefferson, who sent him as military commissioner to the army in South Carolina. The surrender of Cornwallis took place soon afterward, and Monroe returned to pursue his pursuits. In 1782 he was elected to the assembly of Virginia from the county of King George, and in the same year was appointed by that body, although but 23 years of age, a member of the executive council. In 1783 he was chosen a delegate to congress for the term of 3 years, and took his seat on Dec. 18, just in time to be present at Annapolis and witness the surrender by Gen. Washington of his commission of commander-in-chief. Monroe fulfilled his duties in congress with zeal and efficiency. Becoming convinced that it was impossible to govern the country under the old articles of confederation, he advocated an extension of the powers of congress, and in 1785 moved to invest that body with authority to regulate trade between the states. The resolution was referred to a committee of which he was chairman, and a report was made in favor of the measure. This led to the convention at Annapolis, and the subsequent adoption of the federal constitution. Monroe also exerted himself in devising a system for the settlement of the public lands; and was appointed a member of the commission to decide upon the controversy between Massachusetts and New York, relating to their boundaries. Upon the question, which came up during his term, of a relinquishment of the right to navigate the Mississippi river, demanded by Spain, he sided with the southern states, and strongly op-

and the policy of acceding to the demand. He was married about this time to Miss Kortright of New York, a lady celebrated for her beauty and accomplishments. She proved an exemplary wife, and an ornament to every society in which she appeared. Having served out his term, and being ineligible for the next 8 years, Monroe returned to Virginia, and established himself at Fredericksburg, with the view of practising law. In 1787, however, he was re-elected to the general assembly, and in 1788 was chosen a delegate to the Virginia convention to decide upon the adoption of the federal constitution. He had opposed the old articles of confederation, and advocated an extension of the power of congress, as necessary for the good of the country; but the constitution framed by the convention of 1787 did not meet with his approbation. In common with Patrick Henry, George Mason, and other statesmen, he was apprehensive that the adoption of the instrument, without amendment, would confer too great an amount of power upon the general government. He therefore sided with its opponents, and strongly urged the policy of insisting upon previous amendments as the condition of its ratification by Virginia. "He could not conceive," he said, "that a conditional ratification would in the most remote degree endanger the Union, for that it was as clearly the interest of the adopting states to be united with Virginia, as it could be her interest to be in union with them." This policy was opposed by Madison, Pendleton, Marshall, and others; and the instrument was adopted by a vote of 89 to 79, with the proposed amendments simply recommended, Monroe voting in the negative. Although the federal party was in the ascendancy throughout the country, the course of the minority in the convention was fully approved by the great mass of the people of Virginia; and on the death of Mr. Grayson, one of the first senators under the constitution, Monroe was chosen in his place, and took his seat in 1790. He became a prominent representative in the senate of the anti-federal party, and acted with it throughout his term of office, which expired in 1794. In May of that year he received the appointment of minister plenipotentiary to France, to succeed Gouverneur Morris, who had been recalled at the request of the French government. He was received with enthusiastic demonstrations of respect, and publicly embraced by the president of the national convention. The flags of the two countries were intertwined, and Monroe presented the banner of America, receiving in return that of France. This marked exhibition of sympathy with the French republic was however regarded with extreme displeasure by the administration, as an impolitic departure from the neutral policy of the American government. John Jay had been sent to negotiate a treaty with England, and under these circumstances the course pursued by Monroe was considered injudicious and reprehensible, as tending to throw serious

obstacles in the way of the proposed negotiations. On the conclusion of the treaty, his alleged failure to present it in its true character to the French government excited anew the displeasure of the cabinet; and in Aug. 1796, he was recalled, under an informal censure of his official proceedings. On his return to America he published a "View of the Conduct of the Executive in the Foreign Affairs of the United States," in which he set forth the nature of his instructions and defended his action. This publication widened the breach between himself and the administration; but any feeling of personal animosity toward Washington or Jay subsequently subsided, and Monroe remained with both upon terms of warm regard. He did not appear again in public affairs until 1799. In that year, on the nomination of Madison, he was elected governor of Virginia, and filled the office for 3 years. On the expiration of his term in 1803, he was appointed by President Jefferson envoy extraordinary to the French government to negotiate, in conjunction with the resident minister, Mr. Livingston, for the purchase of Louisiana, or a right of depot for the United States on the Mississippi. Monroe was the confidential agent of Jefferson, intrusted with all his views in detail, and, it is said, carried with him verbal instructions to govern him in the proposed negotiation. The result exceeded the most sanguine expectations of the administration. Bonaparte needed money, and within a fortnight after the arrival of Monroe in Paris, the ministers secured for the comparatively trifling sum of \$15,000,000 the entire "territory of Orleans" and "district of Louisiana," thus adding to the United States an extent of country equal to the whole previous territory of the confederacy. Monroe is said to have always taken peculiar pride in the result of his efforts on this occasion, and to have regarded the part which he took in the acquisition of this vast tract as among the most important of his public services. In the same year 1803 he was commissioned minister plenipotentiary to England, as the successor of Mr. King, who had resigned, and exerted himself to conclude a convention for the protection of neutral rights, and against the impressment of seamen. In the midst of these negotiations he was directed to proceed to Madrid, as minister extraordinary and plenipotentiary, to adjust the controversy which had arisen between the United States and Spain in relation to the boundaries of the new purchase of Louisiana. In this he failed, and in 1806 was recalled to England to act with Mr. Pinkney, who had been recently appointed with instructions to negotiate a treaty for the protection of neutral rights. On the last day of that year a treaty was concluded, and soon afterward despatched to the United States. The ministers regarded it as advantageous, but the omission of any provision against the impressment of seamen, and its ambiguity in relation to the other great points of the rights of neutrals, rendered it strongly ob-

jectionable to the president, who refused to submit it to the senate, and sent it back to England for revision. All efforts to attain this failed, and Monroe returned to America. The course of the president in refusing to send the treaty to the senate had excited his strong displeasure, and other circumstances at the time tended to increase this sentiment toward Jefferson. The moment was approaching for the election of president, and a considerable body of the republican party had brought forward the name of Monroe as their candidate. The majority of the party, however, were in favor of Madison, and the preference of the president for him was well known. Monroe believed that the rejection of the treaty, and the preference expressed for his rival, indicated personal hostility on the part of Mr. Jefferson, and a correspondence upon the subject ensued, which proved honorable to both. Jefferson candidly, and with great kindness, explained his course, and showed that his preference for Madison was solely based upon solicitude for the success of the party, the great majority of which had declared in his favor. He further declared that he had not exerted himself in the matter, and should remain entirely neutral. The misunderstanding terminated, and Monroe withdrew his name from the canvass. In 1810 he was again elected to the general assembly of Virginia, and in 1811 chosen a second time governor of the commonwealth. Upon the resignation of Mr. Smith, in the same year, he was appointed by President Madison secretary of state. Gen. Armstrong having resigned the charge of the war department, after the capture of Washington, Monroe was appointed to discharge its duties, which he proceeded to do without abandoning the department of state. He found the treasury exhausted, the public credit at the lowest ebb, and the condition of the country such as would have driven a fearful spirit to despair. With his usual vigor, however, he set about the task of infusing order and efficiency into every portion of the departments under his charge, and proposed an increase of 40,000 men in the army, by levying recruits throughout the whole country. This unpopular measure he advocated without hesitation, although it was calculated to exert a fatal influence upon his prospects for the presidency. His attention was also urgently called to the defence of New Orleans; and finding the public credit completely prostrated, he pledged his private means as subsidiary to the credit of the government, and placed the city in a posture which enabled it to successfully oppose the forces of the enemy. Returning, on the conclusion of peace, to the department of state, he became the confidential adviser of President Madison in the series of measures for the reestablishment of public credit, and the regulation of the foreign relations of the United States. He continued to serve as secretary of state to the end of Madison's administration, in 1817. In that year he succeeded to the presidency,

as the candidate of his party, who were now generally known as democratic republicans with Daniel D. Tompkins for vice-president. The new president's appointments were from the ranks of the party which had placed him in power, and his administration commenced under favorable auspices. Soon after his inauguration he determined to make a personal examination of the condition of the military posts in the North and East, and accordingly set out on May 31, 1817. Passing through Baltimore, Philadelphia, and New York, he visited in all the eastern states, and examined the public works with a critical eye. From Maine he proceeded westward through Vermont to St. Lawrence, embarked for Lake Ontario, and terminated his explorations at Detroit, whence he returned through Ohio to Washington. During this extensive tour he thoroughly inspected arsenals, naval depots, fortifications, and garrisons; reviewed military companies, corrected public abuses, and studied the capabilities of the country, in view of future hostilities. The visit of the new president made him popular with the people, and he was met throughout his tour by civic processions, military escorts, and enthusiastic crowds. The costume which he adopted upon this occasion was calculated to render him popular with the old soldiers of the revolution, and all who remembered the struggle. It consisted of a blue military coat of homespun, light-colored underclothes, and a cocked hat—the undress uniform of officers in the revolutionary war. This suggestive dress added to his plain and unassuming manner, conciliated the people, and the old cocked hat and blue coat no doubt reminded every one of the services of Col. Monroe in the contest for independence. The society of the Cincinnati at New York presented him with an address; and he referred, in the reply which he made, to the times of Washington, and his own former connection, on the battle field, with many of the persons whom he saw before him. In every point of view this journey was auspicious. Party lines seemed about to disappear, and the country to return to its long past state of union. The president was not backward in his assurances of a strong desire upon his part that such should be the case. In reply to an address of the people of Maine, he said: "The further I advance in my progress in the country, the more I perceive that we are all Americans; that we compose but one family; that our republican institutions will be supported and perpetuated by the united zeal and patriotism of all. Nothing could give me greater satisfaction than to behold a perfect union among ourselves—a union which is necessary to restore to social intercourse its former charm and to render our happiness as a nation mixed and complete. To promote this desirable result requires no compromise of principle, and I promise to give it my continued attention and my best endeavors." This assurance was honestly made, and honestly carried out.

He had not appointed a republican cabinet from violent partisan motives. He defended his course in a letter to Gen. Jackson on the ground that "decided friends who stand firm in the day of trial" should "be principally relied on," and that "the administration should rest strongly on the republican party;" but he was in favor of "indulging toward the other a spirit of moderation, and evincing a desire to discriminate between its members." He believed, he said, that "the great body of the federal party were republican," that no second party was necessary to the well-being of the government; and his aim was to bring about a peaceable ascendancy of the principles which he represented. The course of the administration was in conformity with the assurances of the president on his tour, and conciliated the support of an overwhelming majority of the nation. Distinctions of party seemed scarcely any longer to exist, and republicans and federalists coalesced in support of the government. Mr. Clay was reelected speaker of the house, and the great body of recommendations in the president's message were approved by large majorities. The tone of debate was far more moderate; few of the bitter criminations which had been the fashion in the past were uttered; and those "former charms of social intercourse," referred to by the president, seemed about to be permanently restored. Among the important public events of the first term of President Monroe, were the admission into the Union of the states of Mississippi, Illinois, and Maine. At the first session of congress, an animated discussion of the constitutionality of internal improvements by the general government took place, and at one stage of the bill a majority of 15 appeared in the house in favor of using the public funds for the construction of canals, and for military and post roads. The subject was however postponed for the time. Other questions of importance were the policy of recognizing the independence of the South American colonies, and of approving the course of Gen. Jackson, who, having been sent against the Seminole Indians in Alabama, had pursued them into the Spanish possessions in Florida, seized the fortified towns of St. Mark's and Pensacola, and taken possession of the country in the name of the United States. On the first named measure Mr. Clay spoke with great eloquence, but the proposition was rejected by a large majority, though subsequent events vindicated the views of Clay. Gen. Jackson's course was strongly disapproved, as an unwarranted invasion of the territory of a power with which the United States were at peace; and the forts which had been seized upon were ordered to be restored to the Spanish authorities. A strong party, however, supported Jackson; and when, at the subsequent session of congress, a vote of censure upon his conduct was moved, it was rejected by a large majority. In 1818 a convention was concluded between Great Britain and the United States in relation

to the Newfoundland fisheries, the restoration of slaves, and other subjects; and in 1819 Spain ceded to the confederacy her possessions in East and West Florida, with the adjacent islands. In this year the country was first divided into two great parties upon a geographical line, and the debates in congress became angry and embittered. The occasion of this discussion was the bill authorizing the people of the territory of Missouri to form a constitution and state government, for admission into the Union. It was moved to amend the bill by the insertion of a clause imposing it as a condition of admission that the constitution of the new state should contain a prohibition of the extension of slavery within her limits; and upon this the debate took place. The restrictive amendment was rejected, and the bill passed the house with the proviso attached, "that in all the territory ceded by France to the United States under the name of Louisiana, which lies north of thirty-six degrees and thirty minutes north latitude, not included within the limits of the state contemplated by this act, slavery and involuntary servitude, otherwise than in the punishment of crimes whereof the parties shall have been duly convicted, shall be and is hereby for ever prohibited: provided always, that any person escaping into the same, from whom labor or service is lawfully claimed in any state or territory of the United States, such fugitive may be lawfully reclaimed and conveyed to the person claiming his or her labor or service, as aforesaid." The bill passed the senate and was approved by the president, March 6, 1820. The presidential election coming on in this year, Monroe and Tompkins were again nominated and reelected; the former by a vote of 231 out of 232, the latter by a vote of 218. The Missouri agitation was renewed on the question whether her votes for president and vice-president should be counted, but finally terminated with the adoption of a resolution reported by Mr. Clay from the joint committee upon the subject. This resolution provided that Missouri should be admitted "on an equal footing with the original states, in all respects whatever," on condition that the clause contained in her constitution prohibiting the emigration of free negroes into the state should never be construed so as to authorize the passage of any law by which "any citizen of either of the states in this Union should be excluded from the enjoyment of any of the privileges and immunities to which such citizen is entitled under the constitution of the United States." On Aug. 10, 1821, Missouri accordingly became one of the states of the Union. Other events of public importance during the administration of President Monroe were his approval of an act appropriating the sum of \$80,000 for the survey of routes for canals and public roads, by which he gave his sanction to the internal improvement doctrine; the recognition in 1822 of the independence of Mexico, and the provinces in South America formerly under the dominion

of Spain; and the promulgation, in his message of Dec. 2, 1823, of the policy of neither entangling ourselves in the broils of Europe, nor suffering the powers of the old world to interfere with the affairs of the new, now generally known as the "Monroe doctrine." On this occasion the president declared that any attempt on the part of the European powers to "extend their system to any portion of this hemisphere" would be regarded by the United States as "dangerous to our peace and safety," and would accordingly be opposed; a platform of principle upon this important subject which has been approved by the prominent statesmen of the country from the time of its proclamation to the present. The year 1824, the last of Monroe's administration, was signalized by the visit to the United States of the venerable Lafayette, who was received throughout the Union with enthusiastic exhibitions of public affection and respect. On March 8, 1825, Monroe retired from office, and returned to his residence of Oak Hill, in Loudoun co., Va. He was still, however, to serve the public in a useful, if humbler capacity. He was chosen a justice of the peace, and as such sat in the county court; he was also elected one of the board of visitors of the university of Virginia, and displayed great interest in its affairs. In 1829 he became a member of the Virginia convention to revise the old constitution, and was chosen to preside over the deliberations of that body, which he did with great efficiency and dignity. He was compelled, however, by ill health, to resign his post in the convention, and to return to Oak Hill. Pecuniary embarrassment was added to bodily infirmity; and although he had received \$850,000 for his public services, he was in his old age harassed by debt. Under these circumstances he removed in the summer of 1830 to the residence of his son-in-law, Mr. Samuel L. Gouverneur, in the city of New York, where the warmest filial tenderness soothed his latter days. Here he died, like his predecessors Adams and Jefferson, on the anniversary of the declaration of independence. In 1858 his remains were removed with great pomp to Richmond, Va., and reinterred on July 5 in the Hollywood cemetery.—Although not a man of brilliant endowments, Monroe performed an amount of public service which entitled him to the respect and thanks of the country. He held the reins of government at an important period, and administered the affairs of the confederacy with prudence, discretion, and a single eye to the general welfare. He went further than either of his two great predecessors in developing the resources of the country; and although the measures of his administration were not wholly acceptable to the strict republicans of the state rights school of politics, they were approved by the great body of the people, and secured for the president extended favor. The policy which he adopted resembled in important particulars that of the old federal party under Washington, and

conciliated to his support many of the most prominent men of that body. He encouraged the army, increased the navy, augmented the national defences, protected commerce, and infused vigor and efficiency into every department of the public service. His efforts to advance the interests and heighten the general prosperity of the whole nation were energetic and unceasing. On the great question of intervention by the European powers in the affairs of the western continent, he assumed a bold and uncompromising position, which was supported by the people, and has ever since operated as a check upon the governments of the old world. Other features of Monroe's administration have been noticed, to which may be added his approval of the bank of the United States. In relation to internal improvements by the general government, there was long continued hesitation on the part of the president and his cabinet; but the doctrine was eventually sanctioned in the last hours of his administration. When he retired from the presidency he left the country in a high state of prosperity, and carried with him the general respect and regard of the nation. He was well calculated personally to call forth these sentiments from men of all parties. His honesty, good faith, and simplicity were acknowledged by his contemporaries with scarcely an exception, and disarmed the political rancor of his strongest opponents. His friends were devotedly attached to him, and left numerous testimonials of their admiration of his manly integrity and truth of character. Jefferson said that "if his soul was turned inside out, not a spot would be found on it;" and Madison was his warm admirer. "Few men," said Madison, "have ever made more of what may be called sacrifices in the service of the public. When he considered the interests or the dignity of his country involved, his own interest was never regarded. Beside this cause, his extreme generosity, not only to the numerous members of his family dependent on him, but to friends not united by blood, has greatly contributed to his impoverishment." It was the opinion of Madison that the country had never fully appreciated the strong robust understanding of Monroe. The fact may be partially accounted for by his deficiency in the power of public speaking. He never acquired distinction in oratory, a showy talent which in America so largely influences the popular judgment in regard to intellectual endowments. His eminence lay rather in the capacity of administering important affairs with judgment, energy, and laborious industry. These talents he exhibited in a marked degree, and they enabled him to perform his executive functions with an efficiency which has proved of lasting benefit to the country. In person, Monroe was tall and well formed, with a light complexion and blue eyes. The expression of his countenance was an accurate index of the simplicity, benevolence, and integrity of his character. He was plain in his

manners and tastes, fond of the society of his friends, strongly "given to hospitality," and a very fair specimen of the kindly old race of Virginia country gentlemen.

MONROVIA, a seaport town on the W. coast of Africa, capital of the republic of Liberia, in lat. $6^{\circ} 18' N.$, long. $10^{\circ} 50' W.$; pop. about 2,000. It is built on the left bank of the Mesurado river, near its mouth, close to Cape Mesurado. Its appearance from the sea is picturesque; there are several well built stone houses, among which the legislative hall is conspicuous from its size. A stone fort occupies the highest ground in the place, and there are several churches and schools. An academy is supported by voluntary contributions, and there are 2 weekly newspapers. (See **LIBERIA**.)

MONS (Germ. and Flem. *Bergen*), a fortified city of Belgium, capital of the province of Hainault, on the river Trouille, 88 m. by railway from Brussels; pop. 25,000. It communicates with the Scheldt by the canal of Mons, and a branch railway between Mons and Manage opens a direct communication from Paris to Namur and Cologne. The E. side is protected by 2 large ponds, and the defensive capabilities are increased by the facilities for laying the surrounding country under water by admitting the river Trouille. The walls are in the form of a polygon, have 5 gates, and are flanked by 14 bastions. The principal church is that of St. Wandru (Waltrudes), a fine Gothic edifice. Among other principal public buildings are the castle, the Gothic town hall, court house, college, theatre, arsenal, and military hospital. There are several salt and sugar refineries. In the vicinity there are nearly 400 coal pits which give employment to over 26,000 persons. The coal basin in which the city is situated is called the Borinage, and the miners Borains. In coal, flax, hemp, grain, timber, horses, cattle, and manufactured goods, a very active trade is carried on. The number of public schools in 1858 was 181, and of scholars in the royal atheneum 289. Mons is supposed to occupy the site of the Roman station which Quintus Cicero defended against the Nervii during the Gallic war.

MONSEIGNEUR (Fr. *mon*, my, and *seigneur*, lord), a French title once common to saints, and subsequently applied to princes, nobles, certain high dignitaries of the church, and other titled personages. Under the monarchy the dauphin's eldest son was styled *Monseigneur*, without any addition. In France the title is now given only to prelates, French princes, and princes of the imperial family. The Italian *monsignore* has a signification similar to that once given to *monseigneur*.

MONSERRAT. See **MONTSEBRAT**.

MONSIEUR (Fr. *mon*, my, and *sieur*, sir), a French title of gentlemen, corresponding in its original signification and use to the female title *madame*. Under the monarchy it was applied without the addition of the name to the king's eldest brother. It is now given indifferently to Frenchmen of every rank and condition. Dur-

ing the first revolution, and for brief periods in 1880 and 1848, *monsieur* was replaced in general use and in public documents by *citoyen*, citizen. As long ago as the time of Shakespeare the term was applied in a contemptuous sense to Frenchmen by English writers.

MONSOON (Arab. *musim*, season, corrupted by the Portuguese into *mucdo*), an intertropical wind which blows part of the year from one point of the compass, and the remainder of the year in a contrary direction. Though occurring in other parts of the tropical world, these winds are more particularly known in the seas adjoining the great Asiatic continent and archipelago, including New Guinea and the N. part of Australia, whence they extend to about long. $160^{\circ} E.$ The natural causes which produce these currents of air are, in theory, the same as those generally supposed to cause the trade winds. When the sun is in N. latitude and comes over a large portion of Arabia, Hindostan, Burmah, and Cochin China, and these lands become heated to a much higher temperature than the surrounding equatorial sea and atmosphere, the cooler air flows toward these regions; and as they have less rotatory velocity than the latitudes bordering upon the equator whence the current comes, it acquires a relative S. W. direction in passing to the N. and is called the S. W. monsoon. In the northern hemisphere, when the land is cooled by the sun being in S. latitude, the regular N. E. trade wind prevails throughout these seas, and what is called the N. E. monsoon is in reality the N. E. trade wind. South of the equator the S. E. trade wind continues to blow over all that part of the ocean that has not large tracts of land to the S.; but where this is the case, as in the Java seas, and as far E. as New Ireland, where the great Australian continent lies to the S., we find the same causes operating again, and a N. W. monsoon taking the place of the regular S. E. trade wind when the sun has southern declination. These general laws, with trifling exceptions, apply to all monsoons; that is to say, when the S. W. monsoon blows N. of the equator, it blows from the S. E. to the S. of the equator; and when it blows from the N. W. in S. latitude, it blows from the N. E. in N. latitude.

MONSTER, a term limited by Isidore Geofroy St. Hilaire to the complex and grave congenital anomalies of conformation, disagreeable to the sight, rendering difficult or impossible the accomplishment of certain functions, and producing a disposition of organs very different from that ordinarily presented by the species, whether animal or vegetable—involving change in the form, structure, volume, position, and number of parts. This definition greatly simplifies the subject to be treated here, as it excludes simple vices of conformation, such as hare lip, club foot, fissured palate, gigantic and dwarfed stature, albinism, abnormal number of fingers and toes, unusual origin and insertion of muscles, vessels, and nerves; the symmetrical transposition of organs from the normal side of

the body to the opposite (as sometimes occurs in man without serious disturbance of the functions), the general inversion seen in gasteropod mollusks like snails, and the unsymmetrical formation of the flatfish family; it also excludes the varied cases of hermaphroditism. The phenomena of monstrosity were discussed by Hippocrates, Aristotle, Pliny, Galen, and others; but with all the facts collected and the ingenious theories promulgated, they were not examined in a philosophical spirit until the 19th century, when the sciences of comparative anatomy and embryology could be brought to their explanation; the principal workers in the field at this period were the elder Geoffroy St. Hilaire, Serres, and Meckel. The history of monsters, or teratology, is not a mere branch of pathological anatomy, nor of physiology, nor of embryology, nor of philosophical anatomy; it has intimate relations with all these, but must not be confounded with any; it is a science in itself, with its special facts, general laws, and medical and zoological applications. In the fabulous period of this science, ending about the beginning of the 18th century, monsters were regarded as exhibitions of the creative power of God, as proofs of his anger and the signs of some approaching public calamity, or as the work of demons; and as such, by the old Greek and Roman laws, they were at once put to death; even as late as the 17th century they were either destroyed or shut up from human sight. In the first half of the 18th century, when superstition and prejudice began to disappear, the causes of monstrosity were zealously sought for, and from the time of Haller the science made rapid progress; philosophical anatomy, with its proof of the unity of organic composition, and embryology with its facts of arrested development, led to important advances, and introduced order into the previous chaos. Many forms of monstrosity are embryonic conditions rendered permanent beyond the normal period, thus forming a series comparable to the ages of the foetus and to zoological divisions of animals; others seem to be formed by excess of growth, according to the theories of original excess of productive power or of eccentric development of the vascular system; double monsters, whether partial or complete, are united by homologous surfaces, side to side, back to back, or face to face, each internal organ of one having a corresponding organ in the other; and the laws regulating monstrosities, whether by excess or defect, are intimately connected with those presiding over normal organizations. Ia. Geoffroy St. Hilaire (*Histoire des anomalies*, &c., 3 vols. 8vo., Paris, 1832-'6) makes the 2 classes of single and compound monsters, which he divides into orders, tribes, families, and genera on the Linnæan zoological plan; in the 1st class he places all such as have the elements of only a single individual, and in the 2d those which have the parts, complete or incomplete, of 2 or more individuals; for details the reader is referred to the work itself, as only an outline of the divi-

sions can be given here. In the first class he makes 3 orders: A. *Autosites*, or such as are capable of sustaining life, sometimes extra-uterine, by their own organs, having a heart, lungs, almost all the digestive organs, and a portion at least of the head, most of the body remaining symmetrical and nearly normal. This order contains 4 subdivisions or tribes: I., in which the limbs are modified by deficient development or by fusion, or are absent; II., in which the viscera of the trunk are more or less seriously displaced and external, the limbs more or less normal, incapable of extra-uterine life; III., in which the principal anomalies are in the cranium and brain, the modifications of the face and limbs being of secondary importance; the brain is deformed, incomplete, partially or wholly outside the cranial cavity, or even entirely absent, with corresponding deficiency in the arch of the skull; this includes an extensive series both in man and animals, among others the so called anencephalous foetuses, all incapable of life beyond a few hours or perhaps days: in some the spinal canal is largely open, and the spinal cord as well as the brain absent; IV., in which the face is more deformed than the cranium, the nasal apparatus being atrophied or displaced, bringing the eyes more or less near together, or the central region of the face so deficient that the ears are joined on the median line; this includes the one-eyed monsters, like the fabulous Polyphemus (see *Cyclops*), and rhinencephalous foetuses; all these die speedily from the imperfection of the brain. B. The *omphalosites*, living a merely vegetative life ceasing with the separation from the parent, have many of the organs wanting and the existing ones very imperfect, with abnormal and asymmetrical forms; these include the parencephalous and acephalous foetuses, the former having some traces of cranium, but no heart sufficient to circulate blood, and the latter destitute of head except the merest rudiments, often having neither neck nor chest, and but few of the abdominal organs; they never reach the full term of gestation. C. The *parasites* include the imperfect products of conception commonly called moles; they are irregular in form, composed principally of bones, teeth, hairs, and fat, having no umbilical cord, and implanted directly on the parent organs, where they live a vegetative and parasitic life; in most cases they appear to be a deformed and abnormally developed placenta, with a few remains of the prematurely dead embryo; they have been found attached to the uterus and the ovaries, and the gestation has usually been much prolonged, even to years, some of the 2d teeth having been seen in their substance. In the 2d class, or that of compound monsters, the double ones he divides into *autositaires*, in which the 2 individuals present the same degree of development, each having an equal share in the life common to both, a union of 2 *autosites*; and *parasitaires*, composed of 2 very unequal or dissimilar individuals, one complete and the other imperfect.

and the latter capable of living only at the expense of the former. The tribes of the *autotaires* are: I. That in which the individuals are united only in a single region, the duplicity being complete in every other part. This tribe is naturally subdivided into 2 families, according as the umbilicus is double or single; in the former belong the double monsters united by any portion of the trunk or head, like the famous Hungarian sisters, Helen and Judith, joined back to back by the thighs and loins; these were born in 1701, and lived to their 22d year; they had neither the same temperament nor character, and Helen was larger, better looking, more active, intelligent, and gentle than her sister; they were very fond of each other, performed some physiological acts in common and others separately, and were sick and died together. Two black children, united back to back, were exhibited in the United States a few years since. Many interesting psychological, physiological, and pathological questions are connected with such monstrosities, for details of which the reader may consult the authors quoted by Geoffroy St. Hilaire. To the family with a single umbilicus belong such as are joined in the hypogastric and sternal regions, front and sides of thorax, and sometimes even by the neck and jaws. Among those united by the xiphoid region of the sternum are the Siamese twin brothers, Chang and Eng, having a single umbilicus in the centre of the moderate-sized connecting process; they were born in 1811, have been exhibited in most parts of Europe and the United States, and are now residents here, each being married and having a family of children; their respiration and circulation are said to be generally synchronous in the calm state, and their hours of sleep and waking, their joys and sorrows, anger and pain, ideas and desires, to be the same; they realize the idea of perfect friendship, the two being one and each one two in thought and act, and the inevitable confidants of each other; a description and figure may be found in Silliman's "Journal" for 1830. Though these have lived to the age of about 50 years, in the last named members of the group the anomaly is generally incompatible with extra-uterine life. Tribe II. comprises monsters in which the individuals are distinct at the pelvic extremity, but more or less intimately connected in the head and sometimes in the whole supra-umbilical region. In one family the bodies are united from the umbilicus upward, with the head more or less completely double, in some with the 2 faces directly opposite like the Janus of mythology; as far as known, this deformity is incompatible with life. In another family the trunks are joined above the umbilicus, with a single head bearing but few marks of duplicity, and with 2 or 4 thoracic limbs; both these families occur in man, but the latter very rarely. Tribe III. includes, on the contrary, such as have the head double, but the trunks more or less united into a single body and 2 lower extremities; sometimes the

bodies are distinct from the umbilicus upward, with generally a rudimentary 8d lower limb; in others the heads are united behind, but show 2 faces in front. In the *parasitaires* the smaller and less perfect individual may be attached near the umbilicus, or very far from it, and may be reduced to a mere head without body; in some cases the monster seems a single body, with supernumerary jaws, portions of the head or extremities; and in the least perfect of all the accessory growth is included within the principal body. The parasitic growth, from its small size, does not interfere with the birth, and such monsters have not only lived to be adults, but have become parents of well formed offspring. Most authors deny the existence of triple monsters, but Geoffroy St. Hilaire admits it, regarding the quadruple and quintuple cases as equally fabulous with the many-headed Lernean hydra. Under the class of fabulous monsters it will be sufficient to allude to the Minotaur, the centaurs, satyrs, dragons, tritons, sirens, and mermaids of the ancient mythology; to the hideous forms made to represent demons and gods in the pagan schemes of theology; and to such other zoological impossibilities, as creatures half human half animal, still admitted by the ignorant and credulous.—Considering the whole number of births, monstrosities are rare; after man they are most common in the hog, ox, cat, sheep, dog, and chick. Many, if not most, monsters give no indication of anomaly in the course of gestation, and are usually born of mothers in good health and who have previously had normal children; females which bring forth twins have been found most liable to produce monsters, the separate amnions of each from contiguity favoring the confusion or blending of parts; the birth is usually premature, though sometimes long after the natural time; the hereditary transmission of monstrosity is very rare, even when the reproductive functions are unimpaired; the female sex seems to predominate, taking the whole range of monsters. Monstrosity is more common and extraordinary in the vegetable than in the animal kingdom, from the easier derangement and displacement of parts; yet even here it is subject to and explicable by the laws of normal vegetable growth; some botanists consider double flowers and other similar products arising from peculiar culture as monsters, and such as these are perpetuated by seed. Monstrosity may be due to an absence of formation; to an arrest of development, an embryonic structure remaining permanent; to an excess of development; and to a union of parts, more or less normal, belonging to different individuals. Though it is impossible to admit the action of slight causes, of momentary continuance, popularly believed to be connected with monstrous or imitative growths, still the artificial production of variously deformed and imperfect chicks by the shaking, or malposition, or unnatural treatment of eggs, shows that appreciable external causes may occasionally be satisfactorily traced; it is

now generally conceded that long continued unfavorable circumstances acting during pregnancy may lead to monstrous growths. See the numerous works quoted by Geoffroy St. Hilaire, and especially the memoirs of Lemery in the *Histoire de l'académie des sciences de Paris*, 1788 and 1789.

MONSTRELET, ENGUERRAND DE, a French chronicler, born in Cambrai about 1390, died in 1458. Few of the events of his life are known. Throughout his chronicle he never makes the slightest allusion to himself save once, and then he tells us that he was present at the interview between the maid of Orleans and the duke of Burgundy, after the capture of that heroine. He appears to have been well educated, and probably took no part in warlike pursuits. He filled several offices in Cambrai, being bailiff of the chapter, provost of the city, and bailiff of Wallaincourt. His chronicle is in 2 books, extends from 1400 to 1444, and comprises an account of the capture of Paris and the conquest of the French monarchy by Henry V., and of the wars which resulted in the expulsion of the English from every portion of France except Calais. His style has none of the animation and picturesqueness of Froissart, but it is marked by dignity, simplicity, and accuracy. The best edition of Monstrelet's chronicle is that of Buchon (15 vols. 8vo., Paris, 1836). The best English version is that by the Rev. Thomas Johnes (18 vols. 8vo., London, 1810). Appended to the earlier editions of Monstrelet are two spurious books continuing the history to 1467.

MONT BLANC (Fr., "white mountain," so called from the snow which covers it), the highest of the Alps and the highest mountain in Europe, is in Savoy, France, in lat. 45° 50' N., long. 6° 52' E. It extends in length about 18 m. from N. E. to S. W., with a breadth of 5 to 6 m. Its highest elevation, which is but a narrow pinnacle, is 15,775 feet above the level of the sea; and its summit for a distance of 7,000 feet down either side is clothed with perpetual snow. It presents the most magnificent appearance when seen from the north, from the vale of Chamouni, whence it seems to rise into the sky like a dome high above all neighboring peaks. From the southern point of view, from the vale of Aosta, its aspect is wilder and darker with more irregular outlines. The higher parts of Mont Blanc are composed of primitive rock formed in parallel strata in a vertical direction; and its outlying flanks consist of calcareous strata turned up against the great central mass. The sides, to the height of 8,000 to 4,000 feet above Chamouni, are skirted with forests, the more elevated of which contain nothing less hardy than pines and larches. The surface of its higher parts is diversified and very irregular; there are numerous jutting rocks, called *aiguilles* or needles; large fields of ice, often broken into fissures of unknown depth; and grottoes excavated beneath the masses of ice by the warmer temperature below, and hanging with splendid stalactitic formations. Glaciers

frequently sweep down its sides. The beauty of Mont Blanc as it appears in the evening is the wonder of every traveller, and has often been described. Its summit shines with a fair light, almost as if it were one of the heavenly bodies, or as if it had some mysterious principle of light within itself. The phenomenon is thus accounted for: there is high in the atmosphere a zone of thin vapor which is still lighted by the sun after Mont Blanc has ceased to be within range of its rays, and this vapor reflects a part of the light which it receives upon the summit of the mountain. The first ascent of Mont Blanc was made with great danger and difficulty by Dr. Paccard and Jacques Balmat in Aug. 1786; but during the preceding 10 years several unsuccessful attempts had been made. They found the cold so excessive that they remained on the summit only half an hour. The next year De Saussure accomplished the ascent, and made a variety of scientific observations.—See "The Story of Mont Blanc" (London, 1854) by Albert Smith, whose ascent in 1851 and subsequent pictorial and dramatic descriptive entertainment gave unusual popularity to the subject in England for several years. Many ascents are now made every season; a record of two (1856-'9) by Prof. Tyndale is in "The Glaciers of the Alps" (London, 1860). The achievement has lost much of its terrors.

MONT DE PIÉTÉ, the name of a public institution in continental Europe, the original object of which was to deliver the needy from the onerous charges to which they were subjected by Jewish and Lombard money lenders. A Bavarian writer claims the origin of such institutions for the town of Freisingen, where one is said to have been founded in the 12th century under the auspices of a charitable association and with the sanction of Pope Innocent III. It is more generally believed, however, that the first mont de piété was established in Perugia, in the latter half of the 15th century, at the instigation of the pious Father Barnabas of Terni, and that it derived its name (*monte di pietà*) from the hill upon which it was situated. St. Bernard of Feltre founded a similar institution at Mantua, and St. Charles Borromeo prepared the charter for that of Rome. The popes Leo X. and Paul III. issued bulls to express their approbation of these institutions, which were soon established at Padua and in other parts of Italy. The name of SIXTUS V. is associated with the formation of that of Savona. They were introduced into the Netherlands by Wenzel Coeberger, an artist, during the latter part of the 15th century. The earliest one in France was probably that of Rheims. Marseilles, Montpellier, and other French cities possessed monts de piété toward the middle of the 17th century; as in Italy, they were supported by charitable endowments, but they charged interest at the rate of 15 per cent. up on all loans exceeding 5 franca, whereas the Italian institutions only charged a small rate, rarely exceeding 5 per cent, to cover the indispensable

expenses. The mont de piété of Paris was opened Jan. 1, 1778, and was authorized in 1779 to make a loan guaranteed by the income of the *hôpital général*. During the revolution it was closed; and the usurious rates of interest charged by the money lenders during the reign of terror caused its reopening in 1803 to be hailed with delight by the poor of Paris. In 1831 it was placed under the charge of an administrative council, the president of which was the prefect of the department of the Seine. In 1851 the monts de piété were placed under the superintendence of a select committee (*conseil de surveillance*), and were entirely separated from that of the hospitals, with which they had been previously connected. Their income is derived from the surplus funds of other charitable institutions; from the security money deposited in the French treasury by government employees; from the contributions of shareholders; and from loans which the monts de piété are authorized to contract, by issuing bills at 12 months payable to bearer, at the current rate of interest. The Paris mont de piété is situated in the rue des Blancs Manteaux and rue de Paradis, with a branch in the rue Bonaparte, and auxiliary offices in the rue de la Pepinière and de la Montagne Ste. Geneviève. There are also about 20 agents scattered over Paris, appointed by the administration, who are largely employed in the business of loans, but whose onerous charges give rise to considerable complaint. The mont de piété makes advances from 8 francs upward at a rate fixed in 1854 at 4½ per cent. per annum, which may be raised to 5 per cent. whenever the reserve fund deposited in the public treasury is less than 1,200,000 francs (\$400,000), beside which ½ per cent. per month is deducted for the expenses of the establishment; one ninth of these charges is payable in advance. There is also a charge of ¼ per cent. upon the amount of the loan. No money is advanced except upon securities, the value of which is assessed by a committee of 12 appraisers, ½ of the value being advanced upon articles of gold and silver, and ¼ upon all other articles. The articles pledged are sold at public sales at the expiration of a year, unless redeemed (the repayment being accepted in instalments as low as 1 franc) or renewed for another year, with the exception of certain perishable articles, upon which loans cannot be renewed. A receipt is issued for the article pledged, and made out to bearer. The sale of such receipts gives rise to much abuse, which the government has hitherto been unable to check, although a law was passed in 1851 which permits the depositor to demand the sale of his pledges, at the regular period of the public sales, 8 months after their deposit, and accordingly 9 months before the expiration of the loan. The annual receipts and expenditures of the mont de piété are respectively about 40,000,000 francs, with a balance of about 50,000 francs in favor of the institution. The most profitable customers of the mont de piété are not the poor, but the needy of

the higher classes, nearly 400,000 out of 1,200,000 articles deposited annually consisting of jewelry and articles of luxury, the value of which forms ¼ of the total amount advanced. On an average there are about 700,000 articles on hand at the mont de piété, valued at 14,000,000 francs. The daily number of loans made and redeemed is about 4,000, except on Saturdays, when the number redeemed is 5,000 to 6,000, and on the eve of New Year's day and Easter it rises to nearly 10,000. In 1857 the advances amounted to 85,458,914 francs, of which about 8,000,000 was for renewed loans, and the rest new loans upon 1,887,008 articles.—There are in France about 50 monts de piété, and upward of 100 in Holland, not including the small public loan banks in that country, where articles are deposited for the shortest period against the most trifling advances, but at the risk of incurring exorbitant charges, the great number of such offices constituting one of the most remarkable features in the Jewish quarters of Amsterdam. There are upward of 20 monts de piété in Belgium. The principal cities of Germany possess similar institutions, the best managed German mont de piété being in Hamburg. The rate of interest in Germany varies from 8 to 12 per cent.; loans rarely exceed the amount of \$150, and the smallest pledge must be worth at least about \$2, one month being the shortest and a year the longest term of the loan. The rate of interest in the Russian monts de piété is 6 per cent. China is said to possess very ancient institutions of the kind, under the direction of great public dignitaries, which seem to be conducted upon more charitable principles than those of Europe, the rate of interest there being only from 2 to 3 per cent. England and the United States possess no public institutions like the monts de piété, the pawnbrokers' offices in these countries being private establishments.

MONTAGU, BASIL, an English lawyer and author, born in London, April 24, 1770, died in Boulogne, Nov. 27, 1851. He was a natural son of John Montagu, 4th earl of Sandwich, and Miss Ray, who was shot in 1779 at Covent Garden by the Rev. Mr. Hackman, a frantic admirer. Basil was graduated at Cambridge, and after studying at Gray's Inn was called to the bar in 1798. He never attained eminence as a pleader, but acquired a large practice in cases of bankruptcy, to which he principally devoted his attention. He formed an intimacy with that literary circle of which Coleridge was a leader, and became a convert to the political theories of Godwin, under whose influence he meditated abandoning his profession as injurious to society, but was dissuaded from doing so by Sir James Mackintosh. In 1806 Lord Chancellor Erskine made him a commissioner of bankrupts, his experience in which office so impressed him with the evils of the law administered in his court that, by publishing a yearly detail of its pernicious results, and giving evidence against it before a committee of the house of commons, he ultimately induced its amelioration.

Under the new law Mr. Montagu was appointed accountant-general, in which capacity he compelled the bank of England to pay interest (never previously demanded) on the moneys that had been deposited there by his court, and thus recovered about £20,000 for the bankrupt fund. He also distinguished himself by his exertions for the abolition of capital punishment, in advocacy of which he published several works. He was a very voluminous author and editor, having published 40 volumes, and left behind him, it is said, 100 volumes in manuscript. His principal professional work is "A Digest of the Bankrupt Laws" (4 vols. 8vo., London, 1805). Of his editorial works the most important is his edition of "The Works of Francis Bacon, Lord Chancellor of England" (16 vols. 8vo., London, 1825-'84), the last volume of which contains a "Life of Bacon" by the editor.

MONTAGU, EDWARD WORTLEY, an English miscellaneous author, born in Wharfedale, Yorkshire, in 1718, died at Lyons in 1776. He was the only son of Edward Wortley and Lady Mary Wortley Montagu. He ran away from Westminster school, and hired himself as a cabin boy on board a ship bound for Spain, whence after some time he was restored to his friends in England by the British consul at Cadiz. He was next committed to the charge of a private tutor, and sent to travel on the continent. On returning to England he married a woman in very humble life, almost old enough to be his mother, lived with her a few weeks, and then abandoned her. In 1747 he was returned to parliament by the county of Huntingdon, but soon became so involved in debt in consequence of his extravagant habits, that he had to resign his seat and withdraw to France. From France he proceeded to Italy, where he became a convert to the Roman Catholic church; and from Italy to Egypt, where he turned Mohammedan, and is said to have espoused another man's wife. He was disinherited by his father, who ever regarded him with marked aversion. He was returning to England when he died. He wrote "Reflections on the Rise and Fall of the Ancient Republics," and "An Examination into the Causes of Earthquakes," and contributed some papers to the "Philosophical Transactions."

MONTAGU, ELIZABETH, an English authoress, born in York in 1720, died Aug. 25, 1802. She was the daughter of a Mr. Robinson of Horton in Kent, and a pupil of Dr. Conyers Middleton. In 1742 she married Edward Montagu, a grandson of the first earl of Sandwich, who died in 1775, leaving her a large fortune. She made her house a favorite resort for literary characters, and one of the principal places of meeting of the blue stocking club. Dr. Johnson was frequently one of her guests. For many years she gave annual dinners on May day to the chimney sweeps of London. She was the author of 8 "Dialogues of the Dead," published with Lord Lyttelton's (1760), and wrote an "Essay on the Genius and Writ-

ings of Shakespeare" (1799), in refutation of the criticisms of Voltaire. After her death 4 volumes of her epistolary correspondence were published by her nephew, Matthew Montagu.

MONTAGU, LADY MARY WORTLEY, an English authoress, eldest daughter of Evelyn Pierrepont, duke of Kingston, and Lady Mary Fielding, daughter of the earl of Denbigh, born in Thoresby, Nottinghamshire, in 1690, died Aug. 21, 1762. She was related through her father to Beaumont the dramatist, and through her mother to Fielding the novelist, who was her second cousin. She was but 4 years old when her mother died. Her beauty and wit made her the pet of her father, and she acquired the elements of the Greek, Latin, and French languages under the tuition of her brother's preceptors. At the age of 8 years she passed what she deemed the happiest day of her life in the Kit-Oat club, consisting of some of the most eminent men in England, into which she had been elected in a frolic; at 12 she wrote a poetical epistle from Julia to Ovid; at 15 she was meditating the establishment of an English nunnery, and was correcting her education, which she calls "one of the worst in the world," by extensive reading both of works of learning and fancy; and at 20 she made a translation of the *Enchiridion* of Epictetus, probably from a Latin version. Meantime she had lived principally at Thoresby and at Acton, near London, and as the eldest daughter of a widower was wont to preside at the dinner table and to exert her social powers in the entertainment of guests. In 1712 she was privately married to Edward Wortley Montagu, Esq., a country gentleman who had received a classical education, had travelled on the continent, and was intimate with Addison, Steele, Garth, and Congreve. A disagreement concerning the settlements had caused the duke of Kingston to withhold his consent, and the union did not prove a happy one. They lived in the country till after the accession of George I. in 1714, when Mr. Montagu joined the ministry as one of the lords of the treasury. Lady Mary, on her first appearance at St. James's, was hailed with universal admiration, as much for the unrivalled charms of her conversation as for her personal beauty. In 1716 she accompanied her husband to Constantinople, whither he was sent as ambassador to the Porte and as consul-general of the Levant. Her letters while abroad, descriptive of the court and society of Vienna, the scenery and customs of the East, of inoculation, of the sultana Hafsen, of the antiquities, baths, mosques, janizaries, and effendis, are among the finest in literature. They display an intelligence, sagacity, and careful observation, that were then especially rare in travellers, and a sprightliness, raciness, and elegance of style of which there are still few examples. They were published surreptitiously after her death (1762), against the wishes of her family and under circumstances which afforded no guaranty for their authenticity, which, however, is in general

proved by the coincidences of style with her other writings, though it is certain that the text has been tampered with and spurious letters introduced; a 4th volume was published in 1767. While in the East she often resided in Belgrade, once crossed the archipelago to the coast of Africa, and returned by way of the Mediterranean and Genoa. At Belgrade she first observed the practice of inoculation for the small pox, by which malady she had lost an only brother and her own fine eye lashes. In 1718 she applied the process after earnest examination to her only son, then 5 years old; and on her return to England the experiment was tried at her suggestion on 5 persons under sentence of death. The success of the trial did not prevent the most violent clamors against the innovation. The faculty predicted unknown disastrous consequences, the clergy regarded it as an interference with Divine Providence, and the common people were taught to look upon her as an unnatural mother, who had imperilled the safety of her own child. Although she soon gained influential supporters, the obloquy which she endured was such as to make her sometimes repent her philanthropy. On returning to England she had at the solicitation of Pope taken up her residence at Twickenham. A rupture soon took place between them, though he had been one of her most intimate correspondents, according to her statement, because she could not refrain from a fit of laughter when at an ill chosen moment he was solemnly and passionately making love to her; and from that time the poet of Twickenham treated her with constant malice. She wrote many witty verses which had success in society, and some of which were printed. In 1789 her health was declining in consequence of a cancer which ultimately proved fatal, and she went abroad with the intention of passing the remainder of her life on the continent. After short tours, she took up her abode in a deserted palace on the shores of Lake Iseo, in the Venetian territory, and afterward in the city of Venice, where she was residing when her husband died in 1761. She was then persuaded by her daughter, the countess of Bute, to return to England, and died within a year. As a lady of wit and fashion she was the most prominent in her time, and her letters still hold an eminent place in that species of literature. The best edition is her "Letters and Works" (3 vols., London, 1837), by her great-grandson Lord Wharnccliffe, containing full biographical notices; it is now (1860) being critically edited for Bohn's "Historical Library" by Mr. Moy Thomas. Her letters were edited by Mrs. S. J. Hale (New York, 1856).

MONTAGUE, CHARLES, earl of Halifax, a British statesman and poet, born in Horton, Northamptonshire, April 16, 1661, died May 19, 1715. His father was a younger son of the earl of Manchester. Charles was destined for the church, and after distinguishing himself as a foundation scholar at Westminster was sent to Trinity college, Cambridge, where he became a

pupil and friend of Newton. He wrote there in 1685 some verses on the death of King Charles II., which procured him from the earl of Dorset an invitation to London and an introduction to the wits of the town. In 1687 he joined Prior in the composition of a parody in prose and verse on Dryden's "Hind and Panther" under the title of "The Hind and the Panther Transversed to the Story of the Country Mouse and the City Mouse." He signed the invitation to the prince of Orange, was a member of the convention parliament, and soon afterward, having married the countess dowager of Manchester, gave up the church, and purchased the place of one of the clerks of the council. In 1690 he was again returned to the house of commons, where for some years his life was a series of triumphs. He was chosen in 1692 to conduct on the part of the commons a conference between the two houses of parliament relative to a bill for the regulation of trials in cases of high treason; and the eloquence and ingenuity with which he combated an amendment proposed by the lords which gave peers accused of treason the right of trial in all cases by the whole upper house, placed him in the front rank of parliamentary orators. He was soon called to the treasury board and the privy council, and in 1694 was appointed chancellor of the exchequer, in reward for having devised a scheme for the relief of the financial embarrassments of the government. This was no less than the establishment of the bank of England, the plan of which had been proposed by William Patterson 8 years before, but not acted upon. Montague was the originator of the great recoinage act (1695), of exchequer bills (1696), and of the tax on windows. On May 1, 1698, he was made first lord of the treasury, and appointed one of the regency during the king's absence on the continent; but on the reorganization of the ministry in 1699 he was removed to the auditorship of the exchequer. The next year he was raised to the upper house as Baron Halifax. Shortly after the meeting of the new parliament, in Feb. 1701, he was impeached by the commons, together with Portland, Oxford, and Somers, for advising the king to sign the partition treaties and for other alleged offences; but the prosecution was dropped, and the lords dismissed the articles. After the accession of Queen Anne, being now out of office, he was accused by the lower house of breach of trust in his management of the public accounts while chancellor of the exchequer; but he again escaped by the protection of the house of lords. Montague in fact had not borne with decorum his thickening honors. His arrogance, vanity, and neglect of his old friends had made him a host of enemies. Nevertheless, he proposed and negotiated the union with Scotland in 1707, and was one of the judges in Sacheverell's trial, when he voted for a mild sentence. On the death of the queen he acted as one of the regents, and after the accession of George I. was made earl of Halifax and Viscount Sunbury, knight of

the garter, and first commissioner of the treasury. The rank which Montague has held among the British poets is due mainly to his liberal patronage of letters and his high station.

MONTAIGNE, MICHEL, seigneur de, a French essayist, born at the chateau of Montaigne, in Périgord, Feb. 28, 1533, died there, Sept. 13, 1589. His father, supposed of English descent, was an eccentric feudal baron, who had served in campaigns in Italy, was capable of marvellous gymnastic feats, affected learning, and was famous for paradoxes. An athlete and a scholar, he zealously took charge of the physical and intellectual education of his son. The young Montaigne, "before he could speak," was delivered into the hands of a German tutor, imported expressly for the purpose, who could not speak French, and was directed to confer with his pupil only in the classical tongues. The whole household and even the artisans and peasants of the village learned Latin phrases in order to address the youthful lord, who subsequently states that the whole town had been in danger of losing its native speech, and that many Latin words were permanently introduced into its dialect. At the age of 6 years he was able to converse in Latin with ease and fluency; and his study of Greek had been transformed into a game, which, however, he never mastered. At that age he was sent to the college of Guienne at Bordeaux, then the most flourishing in France; was preferred to the first form on his entrance; and at 13 completed the academical course. His natural indolence seems to have counteracted the effect of his precocious scholarship. Love of liberty and laziness were, he says, his predominating qualities through life. Nothing displeased him more than a matter of deliberation. He never looked over his accounts nor revised his manuscripts; wrote so badly that often he could not read his own hand; particularly hated chess on account of the grave attention it required; never touched a book except when he was weary of doing nothing; had an amazing ignorance of common things, which seemed the greater in consequence of his defective memory; could not remember the names of his servants nor of the current coins; would read a book as new which he had scribbled over with notes a year before; would forget his idea while on the way to the library to record it; knew nothing about the agricultural implements, processes, and products amid which he grew up; and could not swim, fence, carve, guess a riddle, saddle a horse, nor make a pen. "Extremely idle both by nature and art," are his words, "I would as willingly lend a man my blood as my pains." With this disposition he soon forgot much even of his Latin, which was as his mother tongue, and confesses that he only nibbled on the surface of science, and that the only books of solid learning he could ever seriously devote himself to were Plutarch and Seneca. After quitting the college of Guienne he began the study of law, and at the age of 21 became a counsellor in the parliament of Bor-

deaux, an office from which he retired in 1573. There began his friendship with Étienne de La Boétie, whom he had loved before meeting him, whose early death he laments in one of the finest of his essays, whose works he edited, and for whom he mourned during the remainder of his life. He was inclined to an easy neutrality amid the religious and political conflicts of the time; declared that any government that was ancient and had been permanent was preferable to alteration; made frequent visits to court, where he was intimate under successive monarchs; married at the age of 33, which, he remarks, was 2 years below the standard of Aristotle and 3 above that of Plato; and at the age of 38 retired to his chateau. He soon after began the composition of his *Essais*, the first volume of which appeared in 1580, which was enlarged in subsequent editions, receiving its final form in 1588. He was already suffering from the stone and nephritic colic, the attacks of which no philosophy could transform into pleasures; and, with no faith in the medical faculty, he determined to seek relief by travelling through the principal countries of Europe. The journal of his tour was discovered and published at Paris in 1774, after having been for nearly two centuries entombed in the family chest in the chateau of Montaigne. The style as well as the antique spelling and handwriting are no doubt of its authenticity. The humors of a valetudinarian seem to have chiefly engrossed his attention. He gauges civilization by its resources and the art of the kitchen. It passes through the scenes of classical antiquity with scarcely a reference to any Roman author. His vanity appears in his ambition for the cordon of the order of St. Michael and for the title of Roman citizen, in his habit of fixing his coat of arms over the door of every room he occupied, in his detailed accounts of attentions received from the great, and in his designation of the burgomaster of Augsburg into the belief that he and his suite were a company of knights and barons. Some of his descriptions, especially of what he saw in Rome, are made with curious felicity. On his return, he was elected to the office of mayor of Bordeaux, which he held for 4 years, maintaining peace in a time of disorder; and after retiring to his domain, in the very focus of civil war, he refused to fortify his house, leaving it "to the stars and guard," and afterward boasted that his frankness had conjured away all dangers from it. He died, surrounded by his friends, prominent among whom was the theologian Charlevoix, at the moment of the elevation in the ceremony of the mass, which at his request was celebrated in his chamber. His *Essais*, to which alone he owes his reputation, profess to have been merely a work of amusement. Informal and irregular, without regard to the rules of art or the show of system, they offer the first modern examples of essays or attempts in distinction from successful and finished works. In an age of pedants, Montaigne appeared as the antagonist of literary

conventionalism, broke through the ceremoniousness of scholastic writing, and defied the domineering pretensions of erudition. His sagacious treatment of every-day life, rich and vigorous language, easy and indulgent gayety, genial egotism, and minute confessions, are among the charms of his work. He defines man as *un être ondoyant*, yielding to all thoughts and all impressions; and he dwells upon the vanity of his wisdom and achievements, the uncertainty, contradictions, fickleness, and failures of the human intellect, even in its best attainments. The motto: *Que sçay-je?* is illustrated by keen perceptions of the strangeness of the commonest things, of the mystery of first principles, of human weakness amid the immensities of the universe, of the force of customary beliefs, of the vast and varying conflict of opinions, and of the absence of any criterion of certainty. He employed the language of Christianity, and both Catholics and Protestants have claimed his sympathies; yet a practical and purposeless heathenism pervades his philosophy. He was a kind of imperfect Socrates, the cross-examiner of his generation, bold, inquisitive, and shrewd, taking nothing on trust, and hating pretence, yet too careless and selfish, and not pure and thorough enough, to give his ideas effect. A monument to him was inaugurated in Bordeaux, Sept. 6, 1858.—There are numerous editions of the *Essais* both in French and English. They were translated into English within 15 years after their publication, and very frequently reprinted in the 17th and 18th centuries. A copy of Florio's translation, the only book known to have been possessed by Shakespeare, is in the British museum with his autograph. The best biographies of Montaigne are by Grün (Paris, 1855), Payen (Paris, 1856), and Bayle St. John (London, 1857).

MONTALANT, MLLR. See DAMOREAU.

MONTALEMBERT. L. MARC RENÉ DE, marquis, a French military engineer, born in Angoulême, July 15, 1714, died March 26, 1800. He was descended from an ancient family of Poitou, and received a thorough scientific and literary education. He entered the army in 1731, took an active part in the sieges of Kehl and Philippsburg, in the campaigns of Italy, Flanders, &c., and in 1741 in the war of the Austrian succession. He afterward devoted himself to the study of military science, and in 1747 became a member of the academy of sciences, and about the same time established foundries for the purpose of casting cannon and heavy ordnance for the navy. During the 7 years' war he acted as French commissioner in the Russian and Swedish armies. His innovations in the art of fortification were opposed by the French engineering corps, but the doubts in regard to the efficiency of his system were dispelled by his successful construction of the fort of Ré. He was also employed in the fortifications of Anklam, Stralsund, and the islands of Aix and Oléron. The works in the last named island were constructed after his system. He became a partisan of the

revolution, and relinquished in favor of the national convention the pension which had been conferred upon him by the government in compensation for the loss of an eye in the public service. During the reign of terror he obtained a divorce from his first wife, who was known as an actress and novelist, and married the daughter of an apothecary. He had given up to the government his foundries, without receiving any equivalent for the large capital invested in them, and was involved in further difficulties by the expenses of publication of his works and of his various experiments for the improvement of the military art, and by the depreciation of the paper money which he had received in payment for the proceeds of one of his estates. He had also executed at his own expense and presented to the government various models relating to fortifications and artillery. He assisted Carnot by his advice, and his services as a military reformer were publicly acknowledged by the convention and by the council of 500, and some pecuniary relief was afforded to him, insignificant however in comparison with his great sacrifices and losses. He is said to have withdrawn his name as a candidate for the membership of the institute as soon as he discovered that Bonaparte was his competitor for the honor. He wrote on the war of 1757, on the siege of St. Jean d'Acre, and a historical essay on the founding of cannon, and contributed valuable memoirs to the academy. His great work, *La fortification perpendiculaire, ou l'art défensif supérieur à l'offensif* (11 vols. 4to., Paris, 1776-'96), with illustrations, absorbed in the publication a large portion of his fortune. The 1st volume shows the defects of bastioned fortifications constructed according to the principles of Vauban, and expounds his system of perpendicular fortification; the 2d treats of the construction of redoubts or small forts; the 3d suggests, as defensive works for seaports and as a mode of simplifying the art of fortification, the construction of a crenellated wall covered by a rampart on which are casemated traverses; the 4th reviews military matters under the reign of Louis XIV., and suggests the formation of lines of intrenchment for the defence of the frontiers of a state; the 5th is devoted to the construction of batteries for the defence of sea coasts; in the next 2 volumes the author refutes the objections against his system; the 8th comments on the forts at Cherbourg and on the island of Aix; the 9th is specially devoted to the illustration of the superiority of the defensive over the aggressive system of warfare, and suggests circular redoubts and casemated star forts; the 2 concluding volumes relate to artillery and fortification. Montalembert was a disciple of the German school, and the opponent of Vauban, which subjected him to the attacks of D'Arçon and of other adherents of the antiquated principles of fortification. His system of detached forts inaugurated a new era not only in fortification, but in the attack and defence of fortresses and in strategical

science generally. The superiority of his intrenched camps over those of Vauban has been fully tested in the wars of Napoleon I., and in more recent military operations. His principles have been adopted in the fortifications of Ehrenbreitstein, in the Maximilian towers at Lintz (imitations of the *tours de Montalembert*), in the forts of Cologne, Sebastopol, Cronstadt, Oberbourg, in the new batteries at the entrance of Portsmouth harbor, and in most modern forts for harbor defence against hostile fleets. Montalembert is justly regarded as one of the greatest engineers that France or any other country ever produced. (See *FORTIFICATION*, vol. vii. pp. 620, 621.) II. MARC RENÉ MARIE DE, count, son of the preceding, born in Paris, July 10, 1777, died June 20, 1831. He served in the army of Condé, and subsequently in the English army with the rank of lieutenant. His marriage with Miss Forbes, daughter of James Forbes, a British merchant resident in Guzerat, procured for him a place in the staff of the duke of Wellington during the Spanish campaign. After the restoration he returned to France, and afterward represented his country at the courts of Württemberg and Sweden. He was raised to the peerage in 1819, and in 1830 gave his adherence to the government of Louis Philippe. III. CHARLES FORBES, count, son of the preceding, a French statesman and author, born in London, March 10, 1810. He received his university education in Paris, and in his 19th year published a small work on Sweden, which introduced him to the acquaintance of M. Guizot. Though educated in the strict Catholic principles of his father, he showed little inclination for his father's absolutist politics, was a disciple of Lamennais, and associated himself with him and Lacordaire in 1830 in founding the democratic ultramontane journal *L'avenir*. While the doctrines of this publication were under examination by the Roman see in 1831, Montalembert and his fellow editors went to Rome to plead their own cause, but met with little encouragement, and in the following year the *Avenir* was formally condemned. In the mean time Montalembert had founded with Lacordaire and De Caux (1831) a free Catholic school in Paris, which was closed by the police. The directors were arraigned before an inferior court for infringing the ordinances on public instruction; but Montalembert, having succeeded to his title by the death of his father, June 20, 1831, availed himself of his rank to have the cause transferred to the court of peers, where in his own defence he delivered his first public speech. The trial, which was only one phase of a long quarrel between the clergy and the university on the subject of education, ended in the condemnation of the young peer to a fine of 100 francs. The papal censure which fell upon Lamennais a few years later had the effect of strengthening Montalembert's attachment to the church, though it did not shake his liberal convictions. He devoted himself to the study of the middle ages, and published in 1836 a

legendary "Life of St. Elizabeth of Hungary, Duchess of Thuringia," with a historical introduction (English translation by Mary Hackett and Mrs. J. Sadlier, New York, 1854), and an essay *Du Vandalisme et du Catholicisme dans les arts* (1840). He spoke frequently in the chamber of peers, where his age gave him all the rights of a member in 1840. In 1842 he opposed M. Villemain's bill for the organization of secondary schools, claiming the right of the church to perfect freedom in matters of education, and protesting against the "university monopoly" which placed all the schools under the control of a faculty of laymen. In 1843 he published his *Manifeste Catholique*, on occasion of the debates in the chamber concerning the relations between church and state. He was now the recognized leader of the Catholic party. He delivered 8 elaborate addresses on the freedom of the church, of education, and of religious orders, in the last of which he eulogized the Jesuits; and in 1847 he founded a religious society to uphold the cause of the Swiss Sonderbund. From time to time he appeared as the advocate of oppressed nations; he spoke in favor of Poland in 1831, 1844, and 1846, and on Feb. 10, 1848, caused a solemn service to be celebrated at Notre Dame in memory of Daniel O'Connell. About the same time, in a speech on radicalism, he predicted a revolution in the course of 3 months. It came sooner than he had expected. At the outset he joined the democratic party, published an address avowing republican sentiments, and was elected by the department of Doubs as a deputy in the constituent assembly. Here, however, he acted rather with the monarchical or moderate party than with the thorough democrats. He opposed the admission of Louis Napoleon, and voted against the new constitution; and toward the close of the session he supported Dufaure's bill for the restriction of the press, and approved the expedition against the Roman republic. Returned to the legislative assembly by the department of Doubs and Côtes du Nord, he became still more conservative in his policy, and found a natural rival in Victor Hugo, with whom he was engaged in some of the most brilliant contests of oratory to which the French legislative halls had listened for many years. He was one of the committee which drafted the law of May 31, abolishing universal suffrage, and was the originator of a bill for the observance of Sunday, which was not passed. Although at variance with the president, he undertook to defend him against his colleagues in the assembly, whom he accused of the blindest and most unpardonable ingratitude. In June, 1851, he had a memorable debate with Victor Hugo on the proposed revision of the constitution. After the *coup d'état* of Dec. 2 he protested against the imprisonment of the deputies, and became more determined in his hostility to Napoleon; but he obtained a place on the second consultative committee, and a seat in the legislative body, where he was almost the only

representative of the opposition. In 1854 a confidential letter from him to M. Dupin, published without his consent in the Belgian journals and circulated in Paris, gave umbrage to the government, and the assembly authorized his being prosecuted, but the tribunals found no ground for action. In the election of 1857 he was superseded by a more acceptable candidate. He has since lived in retirement, employed in literary labors, and contributing frequently to the columns of the *Correspondant*. An article which he published in this journal, Oct. 25, 1858, entitled "A Debate on India in the English Parliament," led to his prosecution on account of invidious comparisons between the institutions of France and Great Britain. He was sentenced to a fine of 3,000 francs and 6 months' imprisonment, which was reduced by a higher court to 3 months; but both penalties were remitted by the emperor. He has been a member of the French academy since 1852. Beside the works already mentioned, he has written *Du devoir des Catholiques dans la question de la liberté d'enseignement* (1844); *Saint Anselme, fragment de l'introduction à l'histoire de Saint Bernard* (1844); *Quelques conseils aux Catholiques sur la direction à donner à la polémique actuelle et sur quelques dangers à éviter* (1849); *Des intérêts Catholiques aux XIX^e siècle* (1852; English translation, 1853); *L'avenir politique de l'Angleterre* (1855; English translation, 1856), in which he attempts to show that the interests of England are identical with those of freedom throughout the world; *Pie IX. et Lord Palmerston* (1856); *La paix et la patrie*; and a review of the memoirs of the duke de St. Simon. The last 3 publications were reprinted from the *Correspondant*. He has contributed to the *Revue des deux mondes* and the *Encyclopédie Catholique*, and is now engaged on a work entitled *Les moines d'Occident depuis Saint Benoît jusqu'à Saint Bernard*, to be completed in 6 volumes, the first 2 of which appeared in Paris in Aug. 1860, and were soon followed by an English translation.

MONTALVAN, JUAN PEREZ DE, a Spanish dramatist, born in Madrid in 1602, died in June, 1638. His father was the king's bookseller, and the son was educated for the church, making such progress in his studies that he became a licentiate in theology at the age of 17. He enjoyed the friendship and instruction of Lope de Vega, and before he had passed boyhood was a writer for the stage. In 1622 he gained a prize for a poem at the festival of San Isidro at Madrid, and soon afterward received the degree of D.D. and an office in the inquisition. The stage, however, was more to his taste than the pulpit. By the time he was 30 years old he had written 36 dramas and 12 *autos sacramentales*, or sacred representations for the festival of Corpus Christi; but the excess of his labors unsettled his mind, and he died insane. He left about 60 plays, two volumes of which he himself prepared for publication. Among the most popular are the "Lovers of Teruel,"

"Most Constant Wife," and "No Life like Honor." He took Lope de Vega for his model, and though he often wrote in bad taste and lacked skill in construction, his dramas are never uninteresting, and are full of fine poetic feeling. He wrote *Orfeo*, a poem (1624); an extravagant "Life and Purgatory of St. Patrick" (1627); a collection of stories under the title *Para Todos* ("For Everybody," 1632); and a panegyric on Lope de Vega (1636).

MONTANELLI, GISEPPE, an Italian author, born at Zuccchio, Tuscany, in 1813. He was graduated as a lawyer at the university of Pisa in 1831, and was one of the early contributors to the patriotic *Antologia* published at Florence, and of other periodicals. He devoted himself to the practice of his profession from 1837 to 1840, when he accepted the chair of Tuscan law and commercial jurisprudence in the university of Pisa. He founded a secret political association and a new liberal journal. Severely wounded at the battle of Curtatone (May 29, 1848), he was captured by the Austrians, and only liberated after the capitulation of Milan. He was appointed by the grand duke of Tuscany a member of his new administration, and after the flight of that sovereign (Feb. 1849) he became one of the triumvirs of Tuscany. Guerrazzi, who was afterward appointed dictator, sent him to Paris to recruit soldiers, and he remained there in consequence of the restoration of the old government of Tuscany. He has published his memoirs (Turin, 1853-'5), and has written for Mme. Ristori a tragedy entitled *Camma*, and prepared for the same actress an Italian version of Legouvé's *Médée* (Paris, 1856).

MONTANISTS, a sect of the 2d century, so called after Montanus of Phrygia. He is said to have been originally a priest of Cybele, and to have announced himself about 160 as a prophet, who was to carry Christianity forward to perfection. He taught a permanent extraordinary influence of the Paraclete, manifesting itself by prophetic ecstasies and visions, assigned to doctrines and rites a subordinate significance, and demanded the most rigid asceticism as a manifestation of internal purity. Beside the ordinary fasts, he prescribed annual and weekly ones, declared second marriages and flight from persecution to be sins, and absolutely forbade the re-admission of some classes of the *lapsi* into the church. He represented the beginning of the millennium as being very near at hand, and Pepuza in Phrygia as the place which would be its centre. His followers, who were also called Cataphryges and Pepuziani, found a zealous and gifted advocate in Tertullian, and included many prophetesses, among whom Maximilla and Priscilla are especially celebrated. The members of the ruling church were designated by them as *psychii*, while they assumed themselves the name *pneumatii*. They were opposed especially by the Alexandrian school, and condemned by several provincial councils. They were very numerous in Mysia, Lydia, and Phrygia, where some towns, as Pepuza and Thyatira, were exclusive-

ly inhabited by them. Thence they spread into other parts of Asia Minor, especially into Cappadocia, Galacia, and Cilicia. In Constantinople and Carthage also they were for some time very numerous. The literature of the modern Tübingen school represents Montanism as a reaction of Jewish Christianity against Paulinism.—See Wernsdorf, *De Montanistis* (Dantzic, 1751; strongly in their favor); Münster, *Effata et Oracula Montanistarum* (Copenhagen, 1829); Kirchner, *De Montanistis* (Jena, 1832); Schwegler, *Der Montanismus und die christliche Kirche des zweiten Jahrhunderts* (Tübingen, 1841); Baur, *Das Christenthum und die christliche Kirche der drei ersten Jahrhunderte* (2d ed., Tübingen, 1860).

MONTANUS. See MONTANISTS.

MONTANUS ARIAS. See ARIAS MONTANUS.

MONTAUBAN, a town of France, capital of the department of Tarn-et-Garonne, on the right bank of the Tarn, 842 m. S. W. from Paris; pop. in 1856, 28,565. It was one of the first towns in France that embraced Protestantism, and the members of the reformed religion there were subjected to direful persecution by Louis XIV. The town contains a college for the education of Protestant clergymen.

MONTCAIRM, LOUIS JOSEPH DE SAINT VÉRAN, marquis de, a French soldier, born in the chateau of Candiac, near Nîmes, in 1712, died in Quebec, Sept. 14, 1759. He entered the army when 14 years old, served in Italy as early as 1734, distinguished himself in Germany under Belle-Isle during the war for the Austrian succession, and fought in Italy again, where he gained the rank of colonel in the disastrous battle of Piacenza (1746). In 1756, being then a brigadier-general, he was appointed to command the French troops in Canada, where he arrived about the middle of May, and soon after began operations against the English with great activity and success. Fort Ontario at Oswego was carried on Aug. 14, after a brisk and well conducted attack. The next year he forced Fort William Henry, at the head of Lake George, which was held by a garrison of over 2,500 men, to surrender at discretion, and thus became possessed of 42 guns and large stores of ammunition and provisions, which were invaluable to his nearly destitute army. Scarcity of food had been one of his great difficulties; the harvest in Canada had failed, and the French government was reluctant to send out supplies which were liable to be captured by the English cruisers. Montcalm had beside to oppose an enemy far superior in numbers and discipline to his own troops, which consisted mostly of Canadian volunteers. Notwithstanding these disadvantages, he held his ground firmly, when, in the campaign of 1758, the English under Abercrombie marched from the south toward the French dominions. Montcalm occupied the strong position of Fort Carillon (Ticonderoga), made it still stronger by intrenchments, in constructing which he worked with the common soldiers,

and at the head of about 8,600 men awaited the attack of over 15,000. After a fierce battle which lasted 4 hours (July 8, 1758), the British retreated in disorder. The personal bravery which Montcalm had evinced increased his popularity among his soldiers; and if he had received timely reinforcements, he could have maintained the supremacy of the French in North America. But the want of energy on the part of the home government, the scarcity of food all over New France, and personal dissensions between the governor and the military commander, forbade him to look for much assistance; and in the midst of victory he expressed his conviction that in a few months the English would be masters of the French colonies in America. Resolved, however, to struggle to the last, and, as he himself said, "to find his grave under the ruins of the colony," he actively prepared for the campaign of 1759. The English, on the other side, spared no exertions to make their conquest sure; troops were sent from Europe; the colonial regiments were thoroughly reorganized; and a strong fleet was to cooperate with the land forces. While Amherst and Prideaux were manœuvring to dislodge the French from their posts in the vicinity of Lake George and Lake Ontario, Gen. Wolfe, at the head of 8,000 chosen troops, supported by the fleet in the St. Lawrence, presented himself before Quebec. The success of the whole campaign, or more properly the conquest of Canada, depended upon the taking of that city; and to protect it Montcalm had concentrated his principal forces on the banks of the Montmorency river. Being attacked in front by Wolfe, on July 31, he repelled him with considerable loss. Wolfe then changed his plans; he secretly landed his troops by night on the left bank of the St. Lawrence, above Quebec, climbed the table land that overhangs the city, and on the morning of Sept. 13 appeared with his whole force on the heights of Abraham, in the rear of the French army. Montcalm flew at once to oppose his advance, and by 10 o'clock the two armies, about equal in numbers, each having fewer than 5,000 men, were drawn up before each other. Montcalm led the attack in person, but his troops soon broke before the deadly fire and unflinching front of the British, and when Wolfe, placing himself at the head of the 28th and the Louisburg grenadiers, gave the order to charge with bayonets, they fell in every direction. The gallant British general fell in the moment of triumph; Montcalm, having received one musket ball earlier in the action, was mortally wounded while attempting to rally a body of fugitive Canadians a few moments after Wolfe was borne from the field. On being told that his death was near: "No, much the better," he said; "I shall not live to see the surrender of Quebec." He died the next morning, and his death was followed by the loss of all Canada, where his career, as Bannister observes, had been "a wonderful struggle against inexorable destiny."

MONTCALM DE CANDIAC. See **CANDIAC**.

MONTEBELLO, a small village of Sardinia, on the road which passes from Alessandria and Voghera through Casteggio to Piacenza, about 5 m. S. of the Po and 1 m. W. of Casteggio. It was the scene of a victory of Lannes over the imperialists during Bonaparte's second Italian campaign, June 9, 1800, from which Lannes took the title of duke of Montebello, and of an engagement between the French and Sardinian allies and the Austrians, May 20, 1859. The latter was the first battle of the Italian campaign of 1859. The allies, whose head-quarters during the month of May were at Alessandria, endeavored, prior to crossing the Mincio at Turbigo and Buffalora (see **MACCETTA**), to create an impression that they intended to attack by Pavia and Piacenza, and with this view concentrated a large part of their force in that direction. The Austrian commander, Count Gyulai, deceived by their movements, accordingly ordered Gen. Stadion to cross the Po below Pavia with 20,000 men, and march along the S. bank of the river, in order to make a reconnoissance in force. About 11 o'clock two brigades of his detachment under Gen. Urban reached Casteggio, which they found occupied by a regiment of Sardinians and 500 men of Gen. Forey's division, belonging to the corps of Baraguay d'Hilliers. These were soon overpowered and driven back through Montebello and Ginestrello toward Voghera; but, reinforced by the arrival of successive detachments from Voghera, they rallied and obliged the Austrians to fall back upon Montebello. Here a final stand was made. Gen. Urban by his rapid advance had deprived himself of the assistance of most of the remainder of Stadion's force, while the French continued to receive accessions, train after train arriving by railway, discharging its hundreds, and hastening back for more. Gen. Forey, bringing up his left to the N. of the village, opened there an effective fire of artillery, while his right wing was engaged in a hot hand to hand combat on the south. The Austrian brigades of Bils and the prince of Hesse at last came up, but the allies continued to maintain a superiority, and about dusk the Austrians retreated. They were not pursued. Their loss in killed, wounded, and missing was officially stated as 1,291, and that of the allies as 850. The Austrians, according to French accounts, had 18,000 men in action, while the allies had 7,000; but the Austrians estimated the force of their enemy as high as 40,000. Both sides claimed the advantage of the battle. The Austrians effected their purpose of ascertaining their adversaries' strength, while the allies confirmed Count Gyulai in the belief that they were about to march toward Pavia.

MONTECUCULI, or **MONTECUCOLI**, RAIMONDO, count, prince of the German empire, and duke of Melfi, an Austrian general, born in the territory of Modena in 1608, died in Lintz, Oct. 16, 1681. He enlisted in 1627 in the Austrian artillery, under his uncle Count Ernesto, and distinguished himself in the 30 years' war. On

Sept. 7, 1681, he took part in the battle of Breitenfeld, where he was severely wounded and made prisoner during the retreat. He was liberated in 1682, and the gallantry he displayed in the assault on Kaiserslautern, July 17, 1685, was rewarded by promotion to a colonelcy. In 1689, while attempting to prevent the Swedes from crossing the Elbe at Melnik, in Bohemia, he was worsted and fell into the hands of the enemy. During a captivity of over 2 years, he studied thoroughly the science of war. On his release he joined the imperial army in Silesia, defeated the enemy at Troppau, and took the town of Brieg. On the outbreak of war in Italy, he repaired thither and received from the duke of Modena the title of brigadier-general and the command of his cavalry; but he soon returned to Austria, was in 1644 appointed field marshal lieutenant and a member of the aulic council, supported in 1645 the archduke Leopold in his expedition against Rákóczy, and was sent to oppose Turenne on the Rhine. The next year, in conjunction with Johann De Werth, he completely routed the Swedes in Silesia, and received the rank of general of cavalry. After the peace of Westphalia he visited Modena; and in 1658, at the marriage festivities of Duke Francis I., he had the misfortune to kill one of his friends, Count Manzani, in a tournament. Being in 1657 placed in command of the army sent by the emperor to protect John Casimir of Poland against the Transylvanians and the Swedes, he forced Rákóczy to make peace. Promoted to the rank of field marshal, he was the next year sent to relieve Denmark, succeeded in rescuing Copenhagen from the attacks of the Swedes, and expelled them from Jutland and the island of Fünen. Peace being finally re-established in the north by the treaty of Oliva (1660), he was intrusted with the command of the army which the emperor sent against the Turks, whom he drove from Transylvania, and kept at bay until he had received reinforcements from Germany, France, and other powers, and gained (Aug. 1, 1664), on the banks of the Raab, the celebrated victory of St. Gotthard, which for the time rid Christian Europe of its Turkish invaders. When in 1672 the ambition of Louis XIV. threatened Holland, Montecuculi was placed at the head of the imperial army which took the field in behalf of the Dutch, and baffled the plans of Turenne, whom he worsted on several occasions. For a while superseded in the command by the elector of Brandenburg, he was soon recalled (1675), as the only general who could hold his ground in presence of the great French marshal. He wisely avoided a pitched battle, and for 4 months conducted a series of operations in so masterly a manner as to elicit the admiration of his opponents. On the death of Turenne he drove the French army across the Rhine, and invaded Alsace; and his progress could be stopped only by the prince of Condé, who obliged him to raise the siege of Haguenau and recross the Rhine. This was the last campaign

of these eminent warriors. Condé, who was but 54, retired to Chantilly; Montecneuli, who was 18 years older, returned to Vienna. He now devoted his time to science, art, and literature. The dignity of a prince of the German empire was conferred on him by the emperor Leopold in 1679, and soon afterward the king of Naples gave him the duchy of Melfi. While accompanying the emperor to Lintz, he was fatally injured by the fall of a beam. One of his favorite sayings was that three things were required for going to war: 1, money; 2, money; and 3, again money. He was noted for his strategical knowledge and for his learning; and he left a personal memoir (translated into Latin under the title of *Commentarii Bellioi*, fol., Vienna, 1718), containing disquisitions on the military art and an account of his campaigns against the Turks. His writings were published in the original Italian by Ugo Foscolo (2 vols. fol., Milan, 1807-'8), and by J. Grassi (2 vols. 4to. and 8vo., Turin, 1821). He is also the author of some poems and of other writings still unpublished.

MONTÉGUT, ÉMILE, a French author, born in Limoges, June 24, 1826. He studied law, but devoted himself to literature. His first article in the *Revue des deux mondes* appeared in 1847, and was followed by many other elaborate and discriminating reviews, which have placed him in the front rank of French essayists and critics. He was among the first to familiarize the French public with the writings of Emerson, of whose essays he has made a translation, with an introduction (Paris, 1850). He has also begun a translation of Macaulay's "History of England" (vols. i. and ii., 18mo., 1858). In 1858 appeared a collection of a number of his essays under the title of *Libres opinions, morales et historiques*, the most remarkable of which are on Werther, on universal monarchy, on human individuality in modern society, and on the omnipotence of industry. Since 1857 he has been the regular literary editor of the *Revue des deux mondes*, to which he is also a constant contributor.

MONTEMOLIN, COUNT OF. See CARLOS, vol. iv. p. 489.

MONTEN, DIETRICH, a German artist, born in Düsseldorf in 1799, died in Munich, Dec. 18, 1848. He studied at the academy of his native city, and under Peter Hess at Munich, and enlarged his knowledge by the inspection of the principal collections of art in Italy and Germany. He became eminent as a painter of battles, and was employed by Cornelius in preparing the battle scenes of one of his most celebrated frescoes. Among his most esteemed works are "The Departure of the Poles from their native Country in 1831;" "The Death of Max Piccolomini;" "The Death of Gustavus Adolphus near Lützen;" and "The Death of Duke Frederick William of Brunswick in the Battle of Quatrebras."

MONTENEGRO, or TOHERNAGORA (Turk. *Karadagh*; Alb. *Mâl Zëra*, or *Mâl Eryé*, Black Mountains), a half independent principality in Turkey near the gulf of Cattaro and lake of Scu-

tari, bounded N. by the Turkish provinces of Herzegovina and Bosnia, E. and S. by Albania and W. by the Dalmatian circle of Cattaro, between lat. 42° 10' and 42° 56' N., and long. 14° 41' and 20° 22' E., including the eastern Kutsch district, which seceded in 1848 from Montenegro; area, about 1,500 sq. m.; pop. nearly 150,000, chiefly Slavic, $\frac{1}{2}$ of whom are fighting men. It is divided into 8 departments or *sandjaks*, each composed of several communes. Capital, Cetigne. It has hardly any plains. The limestone ridges of the Dinaric Alps which traverse it occasionally diversified by lofty peaks, are so rugged and rocky that the people have the common saying: "When God was in the act of distributing stones over the earth, the bag that held them burst and let them all fall upon Montenegro." The highest summits of the principal mountains reach from 5,000 to 6,000 feet. The few larger streams, as well as the small rivers, all run into the lake of Scutari. The most common trees are the alder, ash, beech, fir, hazel, oak, ilex, walnut, willow, and poplar. The most valuable tree is the sumach called *scottano* (*rhus cotinus*), the wood of which yields a yellow dye; its leaves are used for tanning leather. The mulberry, olive, peach, pomegranate, and other fruit trees, and the vine, are cultivated, and flourish particularly in the department of Tchernitza, between the lake of Scutari and Dalmatia, which produces honey, almonds, figs, excellent quince, and was superior to that of Dalmatia. The chief productions are maize (which grows in the greatest luxuriance in the valley of Bielopartich), potatoes, and tobacco. Agriculture is in a backward condition, but every piece of land capable of tillage is planted. Goats, pigs, and sheep are numerous. The winters in Montenegro are very cold, but the climate is healthful and invigorating. The total number of settlements is between 300 and 800, mostly villages situated in hollows and on the slopes of mountains, with the houses or huts in many instances detached and scattered. In the most desolate parts of the country the Montenegrin huts are even more miserable than Irish mud cabins. The people bake their bread in the ashes, without leaven. Chimneys are almost unknown, as well as watches and clocks. Of the inhabitants an English writer says: "All appear muscular, strong, and hardy in Montenegro; and the knotted trees, as they grow amid the crags, seem to be emblematical of their country, and in character with the tough sinewy fibre of the inhabitants." The men attend to the tillage of the land, but never lay aside their arms and never undress during the night, being always ready for marauding expeditions and for encounters with the Turks. All the inferior drudgery of in-door and out-door work is performed by the women. The men wear a white or yellow cloth frock, reaching nearly to the knees, secured by a sash round the waist; under it is a red cloth vest, and over it a red or green jacket without sleeves, both richly embroidered, and the whole covered with

a jacket bordered with fur. They wear a red Fes cap and white or red turban, below which protrudes at the back of the neck a long lock of hair. The women wear a frock or pelisse of white cloth and open in front, but much longer than that of the men, and trimmed with various devices and with gold ornaments in front as well as round the neck. The red cap of the girls is covered with Turkish coins arranged like scales. The red cap of the married women has instead of coins a black silk border, and on gala days a bandeau of gold ornaments. Women and men wear *oponche* (sandals), the soles of which are made of untanned ox hide, with the hair taken off and that side outward, and which enable them to run over the steepest and most slippery rocks with facility. Men and women carry the *struch* (somewhat like the Scotch plaid) over their shoulders. The chief occupation, next to agriculture, is fishing; but their favorite pursuit is pillage and war. Like the old Scotch borderers, they consider their forays for cattle as feats of chivalry. From their earliest childhood they spend their leisure time in firing at a target. M. Bronieffski, a Russian naval officer who travelled in Montenegro, says: "A Montenegrin is always armed, and carries about during his most peaceful occupation a smooth-barrelled gun of great length, pistols, a yataghan (a long knife for cut and thrust worn in the girdle), and a cartridge box. He climbs the steepest rocks with the greatest facility, and bears with patience hunger, thirst, and every privation. Inhabiting mountains which present at every step passes where a handful of brave men may arrest the progress of an army, the Montenegrins are not afraid of a surprise, particularly as they have on their frontier a constant guard; and the whole of their force may be collected within 24 hours upon the threatened point. When the enemy is in great force, they burn their villages, devastate their fields, and, after having enticed him into the mountains, they surround him and attack him in a most desperate manner. When the country is in danger, they forget all personal feelings of private advantage and enmity; they obey the orders of their chief, and like gallant republicans they consider it a happiness and a grace of God to die in battle. It is in such a case that they appear as real warriors; but beyond the limits of their country they are savage barbarians, who destroy every thing with fire and sword." The heads of the slain are exposed as trophies, and medals are given to those who have taken a stated number.—The imports of Montenegro are cattle and some horses, tobacco, salt, copper, iron, oil, wax candles, wine, brandy, coffee, sugar, arms, gunpowder, lead, flints, glass, shoes, sandals, Fes caps, &c. The exports are smoked mutton, sumach wood and leaves, salted and dried fish, wax, honey, tobacco, vegetables, fruits, cattle, some silk, &c. The principal market is Cattaro. Carts being unknown, the produce is carried thither chiefly by women, and it is only in the eastern regions of the country that they are assisted

in their labor by the use of mules and asses. Though so near the sea, there is no port and no outlet to the shore, and the Montenegrins are dependent on the Austrian government for permission to pass the goods intended for exportation or received from abroad by way of the Adriatic. Manufactures are limited to articles of immediate necessity. The daily wages of a laborer are a piece of 20 *carantani*, equal to 16 cents. This and other Austrian coins and Turkish paras (chiefly used as female ornaments) are the only currency, no money being coined in Montenegro. Taxes are levied on each household, the total amounting to about \$15,000 annually, which, together with duties on salt, fish, and dry meat, the monopoly of tobacco, the land rent of several convents, and the amount contributed by Russia toward the public expenditures of Montenegro, make up an annual revenue of nearly \$40,000.—The Montenegrins are all of the non-united Greek church excepting a few Roman Catholics, and every village has its church. The spiritual and secular power was united in the *vladika* or prince bishop until after the accession of the late Prince Danilo (1852). The number of priests is about 200; they join in war and the other occupations of the people, and some of them hold office or are engaged in trade. The czar is the head of the church. As the marriage of priests must take place before they can be consecrated, the marriage ceremony is performed during childhood, and the young girl destined to become the priest's wife is facetiously called *popaya*. The principal convents are those of Cettigne, Ostrok, and St. Stefano. Education is neglected, and many of the priests are unable to read and write. Several schools were established however in 1841, and a printing press in Cettigne, which has issued a Montenegro almanac and several books.—The language of Montenegro is a very pure dialect of the Slavic, not corrupted by admixture with foreign words. The people themselves call it a Servian dialect, and Count Krasinski states, in his "Montenegro and the Slavonians in Turkey" (London, 1855), that "it is considered the nearest of all the Slavonian dialects to the original Slavonic tongue; i. e., that into which the Scriptures were translated by St. Cyril and Methodius in the 9th century, and which still continues to be the sacred tongue of all the Slavonian nations who follow the eastern church."—In ancient times Montenegro formed part of Illyricum. The present principality afterward constituted the S. W. corner of the old kingdom of Servia, which in the 14th century, under the reign of Stephen Dushan, extended from the Adriatic to the Black sea, and from the archipelago to the Danube. Toward the end of that century King Lazarus lost his throne and life, and Servia became tributary to the Porte. Montenegro, or Zita as it was then called, secured its independence under the rule of Prince George Balaha, who had married a daughter of the late Servian king. Their son Stratzimir was called from his dark complexion Tchernoi (black), and

gave his name to the family of Tchernoievitch, first adopted by Stephen, the son of Stratzimir. Stephen was a contemporary of the famous Albanian chief Oastriot, better known as Scanderbeg, whom he assisted against the Turks. On the death of Scanderbeg (1467), Montenegro as well as Albania was invaded by the Turks, and Ivan Tchernoievitch, who had succeeded his father Stephen as ruler of the former country, was compelled to evacuate the town of Zabliak, which had been the capital of himself and his predecessors, and to retire to Cettigne, which henceforth became the seat of the government, and the metropolitan see (1485). Ivan's son and successor, George Tchernoievitch, was the last secular ruler of Montenegro. Having married a Venetian lady, he retired with her to her native city, transferring the government to the hands of the spiritual chief, from which time (1516) dates the commencement of the theocratic form of government in Montenegro. Turkey regarded and still regards Montenegro as a portion of the pashalik of Scutari, and in 1628 Suleyman, pasha of Scutari, invaded the country with a powerful army, but was repulsed with severe losses. In the latter half of the 17th century Danilo Petrovitch was elected vladika or prince bishop, and from that time the power has continued in the Petrovitch family. At the beginning of the 18th century the Montenegrins sought the protection of Russia against Turkey, engaging to coöperate with the czar in his wars against the Porte, and made several incursions into the enemy's territory. The Turks thereupon sent several expeditions to Montenegro, one of which in 1714, consisting of 120,000 men, defeated the Montenegrins, upward of 20,000 of them being carried into captivity; the Turks laid waste the country with fire and sword, and the vladika was compelled to seek refuge in Venice. The war that followed between the Turks and Venetians caused the former to abandon Montenegro, when the fugitive inhabitants returned and rebuilt their villages. During all this time the Montenegrins continued to receive pecuniary assistance from Russia. From 1767 to 1773 an adventurer named Stiepan Mali (Little Stephen) obtained much influence over a great part of the population of Montenegro by passing himself off as the czar Peter III., who had been strangled in 1762, although he was denounced as an impostor by the vladika and the Russian government through a special envoy, Prince Dolgoruki. He finally lost his influence by his want of personal courage, and was murdered in the convent of Stanievitch, to which he had retired. In 1768 the gallant mountaineers again resisted the Moslem invaders; and during the Russian-Austrian war against the Porte they defied the Turks within their own territory. In 1796 a battle was fought between the Montenegrins under their vladika, Pietro I., and the Turks under the pasha of Scutari, which was the most decisive that ever took place between them, and established the virtual independence of the country; 80,000 Turks

perished, and the moral effect of this victory has continued to the present day. At the close of the 18th and beginning of the present century the Montenegrins aided the Russians against the French in the attack on Ragusa, the capture of Ourzola, and on other occasions. After the peace of 1814 the Montenegrins remained for some time in quiet. In 1820 their territory was again invaded by the Turks under the vizier of Bosnia, who were completely defeated and obliged to retire with heavy loss. The conflicts with the foreign enemy, however, were no sooner terminated than the tranquillity of the country was disturbed by bloody feuds at home. The highly revered vladika Pietro I., on the day before his death (Oct. 17, 1830), implored his subjects to abstain in future from intestine commotions; and his successor Pietro II. introduced various reforms in the administration of justice, and established a senate, now consisting of 12 members, in whom the executive power was vested. All taxes were abolished, the emperor Nicholas having on his accession in 1825 paid 17 years' arrears of the annual Russian contribution of about \$20,000. The Turks attacked the country in 1832 in order to regain one of the departments which had joined Montenegro in the preceding year, but were repulsed. Hostilities with Austria were terminated by the treaty of 1840, by which the Montenegrin boundary was defined. From that time, however, till the death of the vladika (1851), the country was again distracted by almost uninterrupted skirmishes with the Turks. His successor and nephew Danilo, after having received in St. Petersburg in due form the title and dignity of prince bishop, afterwards commenced his reformatory measures by separating the religious from the civil power, and assuming the throne as the first secular prince under the name of Danilo I., which caused Russia to withdraw her subsidies (but more recently they were again paid into the Montenegrin treasury), and which, together with the imposition of onerous taxes, caused much agitation in the country. This was skilfully used by the Turks in fomenting insurrections in various parts of Montenegro, and in reasserting their claims upon the possessions of the territory. The Pasha entered upon formidable operations against the Montenegrins, Jan. 12, 1853; although his enemies successfully invaded his own camp (Jan. 16), Grahova was stormed (Jan. 19), and the position of Montenegro was most critical, when peace was restored by the intervention of Austria and by the mediation of other powers, about Feb. 15, 1853. The Pasha sought in vain to obtain the acknowledgment of the sovereignty of Montenegro by the European powers, although he repaired at the beginning of 1857 to Paris for the furtherance of that object. His endeavors to establish a permanent settlement with Turkey were likewise unsuccessful, while at home his government was obstructed by conspiracies chiefly instigated by his uncles. Danilo however displayed much en-

ergy in improving the laws and the condition of the country, but also much cruelty in punishing his opponents. Many executions took place, and among those banished to Constantinople was the young and talented Montenegrin poet Stephen Petrovitch Ouca, whose death (June 10, 1857) was greatly deplored. Fresh collisions with Turkey took place in 1858; and one of Danilo's uncles was detected in treasonable proceedings. From that time until the present the country has remained in an unsettled condition, in the midst of which Danilo was assassinated (Aug. 11, 1860) and succeeded on the throne by Nicolò Petrovitch, who was, from Aug. 1856, to March, 1860, a pupil in the lyceum of Louis le Grand in Paris, and who is described as an accomplished young man, of great independence of character. His first official act was to dismiss the bishop of Montenegro, on account of his conduct during the funeral of the late prince. An insurrection was suppressed in blood.

MONTEREY, a W. co. of Cal., bordering on the Pacific, bounded E. by the coast range of mountains, intersected by the Salinas or Buena Ventura river, and drained also by the Carmelo, San Benito, and Pajaro; area, 5,000 sq. m.; pop. in 1856 estimated at 4,592. The surface is traversed by several elevated ranges, and is principally employed for stock raising; about 50,000 acres are estimated to be susceptible of cultivation, of which about 8,000 were in 1858 under the plough. The best land lies in the valleys of Pajaro, San Juan, Carmelo, and Salinas, and the varieties of elevation permit the production of a great diversity of fruits, of which those that reach the greatest perfection are the fig, peach, apricot, grape, apple, pear, and olive. Silver, copper, lead, quicksilver, and granite are among the mineral resources. The productions in 1858 were 28,610 bushels of wheat, 6,428 of barley, 6,000 of beans, 245,000 of potatoes, 4,080 tons of hay, and 20,000 lbs. of butter.—MONTEREY, the capital, is on the S. side of the bay of the same name, in lat. 36° 36' 4" N., long. 121° 52' 25" W., 94 m. S. S. E. from San Francisco; pop. in 1856 about 2,500. The harbor affords an excellent anchorage, but is exposed to the prevailing N. W. winds. It was selected in 1770 by Father Junipero Serra for a missionary station, and was the capital of California until 1847. The old town is built of adobe, the modern chiefly of wood.

MONTEREY, a city of Mexico, capital of the state of Nuevo Leon, on the San Juan river, a tributary of the Rio Grande, about 80 m. N. E. from Saltillo, and about 500 m. N. from the city of Mexico; pop. in 1858, 17,399. From its position near the Rio Grande it carries on an extensive commerce with the towns on that river, and receives large quantities of American goods, which are distributed to various parts of Durango and Zacatecas. Its increasing business has made it the most thriving city in northern Mexico. Its houses are well built, chiefly of limestone; but some are constructed of adobe. The streets are paved and clean. The city stands

upon a broad plain 1,626 feet above the level of the sea, and is embosomed among beautiful gardens and orchards.—In the early part of the war between the United States and Mexico, Monterey, which occupies a strong natural position and was well fortified by art, was held by the Mexican Gen. Ampudia with about 10,000 regular troops. In Aug. 1846, Gen. Taylor, with a force of 6,625 men, mostly volunteers, marched from Matamoras to attack Monterey; and on Sept. 9 he encamped within 8 miles of the place. Ten days were spent in reconnoitring, and on the afternoon of Sept. 19 Gen. Worth was ordered to march with his division around the hill occupied by the bishop's palace, to take a position on the Saltillo road, and to carry the enemy's detached works in that quarter, while the main body of the army were to make a diversion against the centre and left of the town by batteries erected during the night. In the morning these batteries opened upon the city, which replied by a heavy fire from the citadel and other works. The lower part of the city was assaulted and entered by the Americans, and a Mexican work of great strength captured after hard fighting by a brigade under Gen. Quitman. Gen. Butler also entered the town at another point with the first Ohio regiment. Meanwhile Gen. Worth carried the heights south of the river and the Saltillo road, and turned the guns of the Mexican works in that quarter upon the bishop's palace. The Mexicans evacuated the lower part of the city during the night, and early next morning Gen. Worth stormed the height overlooking the bishop's palace; and by noon that stronghold itself was taken by the Americans, and its guns turned upon its flying defenders. The houses of the city being solidly built and capable of defence, and the streets strongly barricaded, the Americans were forced to take each house in succession by breaking through the walls till they reached the principal plaza. The conflict lasted till the 23d, the Mexicans contesting desperately every foot of ground till nothing remained in their possession but the citadel. On the morning of the 24th Gen. Ampudia capitulated, and was allowed with his army to march out with the honors of war. The loss of the Americans in these operations at Monterey was 120 killed and 368 wounded. That of the Mexicans was not ascertained, but was probably much greater.

MONTESPAN, FRANÇOISE ATHÉNAÏS DE ROCHECHOUART DE MORTEMART, marquise de, one of the mistresses of King Louis XIV. of France, born in 1641, died in 1707. She was first known by the name of Mlle. Tonnay-Charente, and figured among the maids of honor to the duchess of Orleans. At the age of 22 she married Pardaillan de Gondrin, marquis of Montespan, was officially presented at court, and became lady in attendance to the queen. Her "surprising beauty," graceful figure, wit, and conversational powers at once made a sensation; but for several years the king seemed scarcely to notice her. At last, when he began

to tire of Mlle. La Vallière; he turned his eyes upon the brilliant marchioness, who secretly became his mistress about 1668, and was openly declared as such two years later. Her husband vainly attempted to prevent or at least to break off the connection; his passionate appeals and reproaches were answered by banishment to his estate. There he dressed in black like a widower, and entirely ignored his faithless spouse, from whom he was legally separated in 1676. Mme. de Montespan for 14 years was the soul of the court, and the dispenser of favors. Her influence over the king was unbounded; she prevailed upon him to legitimate their children, who were confided to the care of the widow Scarron, afterward Mme. de Maintenon, who in time supplanted Mme. de Fontanges, the immediate successor of their mother in the royal affections. She was not easily reconciled to a separation, but clung obstinately to what she considered her "office," and spared no exertions to bring the king back to her. Finally deciding to leave the court in 1686, she first retired to a convent and tried in vain to be reconciled to her husband. She now devoted herself passionately to religion, subjecting herself to penance and mortification, distributing most of her income to the poor, and endeavoring in every way to make amends for her past follies. Her mind, however, could not gain peace; and during a journey to Bourbon L'Archambault, made to relieve her restlessness, she was seized by an illness which suddenly ended her life. Her children by the king were: the duke of Maine, Mesdemoiselles de Nantes, de Blois, and de Tours, and the count of Toulouse, beside 8 others who died in childhood.

MONTESPAN, LOUIS ANTOINE DE PARDAILLAN DE GONDRIN DE. See ANTIN, MARQUIS D'.

MONTESQUIEU (CHARLES DE SECONDAT, baron de la Brède et de Montesquieu), a French publicist and philosopher, born in the chateau de la Brède, near Bordeaux, Jan. 18, 1689, died in Paris, Feb. 10, 1755. His father and grandfather were presidents of the parliament of Bordeaux, and he himself was destined to the magistracy. He was remarkable in youth for diligent studies not only of jurisprudence but of literature and philosophy, and he afterward declared that books had been to him a sovereign remedy against the ills of life, his troubles having always been dissipated by an hour of reading. Delighted with the authors and philosophers of antiquity, he composed a work at the age of 20 designed to prove that their paganism did not merit eternal damnation, which, however, he refrained from publishing. At the age of 25 he was admitted to the parliament of Bordeaux, of which he became president *à mortier* two years later, succeeding his uncle in that office. He applied himself scrupulously to its duties, though taking little interest in them, understanding, as he confesses, the questions but not the processes, and was chiefly devoted to the pursuits of literature. He was a member of a literary and musical society

formed at Bordeaux in 1716, which through his influence was transformed into an academy of sciences, to which he contributed memoirs chiefly on natural history. The weakness and near-sightedness of his eyes, resulting finally in almost entire blindness, forbade the prosecution of this study. Among his other early writings were dissertations on the physical history of the earth, published in 1719, and on the policy of the Romans in their religion. His first work that attracted general attention was the *Lettres Persanes*, which appeared anonymously in 1721, and has been styled the most profound of frivolous books. It consists of letters represented to have been written by a Persian travelling in France to his friends at home, in which he discusses the manners, government, and events of the times of Louis XIV. and the regency, assailing beneath a transparent veil the whole system of principles prevalent in church and state. It abounds in paradoxes, jests, and sprightly satire, and also in profound views of law, commerce, and social problems; it represents not the popular thought, but the ideas of the best society of the time; and its success was so great as to be almost proverbial. This is the only one of his writings in which he employs the weapon of ridicule, and boldly treats religion and morals. In 1725 he printed the *Temple de Guise*, a romance of classical antiquity, styled by Mme. de Deffand the "apocalypse of gallantry," which lacks vigor, and was withdrawn and disowned. In 1726 he retired from the magistracy to devote himself solely to literature; was received into the French academy in 1728, having overcome the opposition of Cardinal Fleury by modifying obnoxious passages in his *Lettres Persanes*; and soon after began to travel through the principal states of Europe to collect materials for an elaborate work on politics and jurisprudence which he had been long meditating. At Vienna he became intimate with Prince Eugene; passed thence through Hungary; at Venice he was acquainted with John Law of Lauriston, then in obscurity after the calamitous delusions of the Mississippi scheme, and with the count of Bénéval, then in the midst of his romantic career; resided next in Rome and Genoa; travelled through Germany to Holland; and sailed thence with Lord Chesterfield to England, where he remained about two years, was received into the royal society, and was treated with distinction by persons of the highest eminence. His residence in England produced a great effect upon his subsequent writings, reconciling him to many features of social order which he had previously assailed. Germany, he said, is made to travel in, Italy to sojourn in, England to think in, and France to live in. He returned to La Brède after an absence of 4 years, and after 3 years of retirement published his *Considérations sur les causes de la grandeur et de la décadence des Romains* (Paris, 1784), the best written of his productions, discussing the period from the foundation of Rome to the conquest of Constantinople by the Turks. Its epigrammatic and

ences, confident tone, and oracular judgments on great masses of facts were calculated for the public taste of the time, and contributed to its success. Penetrating to the peculiar genius of the Roman state, he explains its progress as the triumph of tyranny and its decline as the fatality of slavery. His great work, entitled *De l'esprit des lois* (8 vols., 1748), one of the most valuable products of French philosophy in the 18th century, was the mature fruit of all his studies and the result of 20 years of labor. So great was its success that 22 editions were issued in 18 months, and it was translated into most of the European languages. It was read not only by the learned, but by men of the world and ladies, who thought, by perusing its short chapters and entertaining volumes, to attain a solid acquaintance with history and philosophy, legislation and politics, constitutional order and financial science. Laws and governmental theories became fashionable topics of conversation in the Parisian saloons. Voltaire said that "when the human race had lost their charters, Montesquieu found and restored them." The work attracted at first more attention in England than in France or Germany, but soon became the oracle of the friends of moderate freedom, distinguished from the destructive tendencies of the school of Voltaire and the unhistorical and impracticable tendencies of the followers of Rousseau. It regarded constitutional monarchy, the principle and foundation of which is the sentiment of honor, as the destiny and last refuge of the European races. Montesquieu has from this time held a most prominent place in the philosophy of jurisprudence and politics. He passed the remainder of his life alternately at La Brède and Paris, in his study and in society. The severe labors which he had imposed upon himself in the composition of his principal work had enfeebled his naturally delicate health, and an attack of fever on a visit to Paris terminated fatally. By his own confession, he was one of the happiest of men. With a philosophic repose of character, a perfect equilibrium of faculties and of passions, he passed in ease a quiet and thoughtful life. The piquant and seemingly malicious bon-mots attributed to him were plays of wit and not products of serious feeling. His kindness and beneficence were constantly experienced by the peasants of La Brède and by many other persons. His monument was inaugurated in Bordeaux, Sept. 6, 1858. Among his minor writings are academical discourses; the *Dialogue de Sylla et de Evorate*, an explanation of the political conduct of Sylla; and an *Essai sur le goût*, written for the *Encyclopédie*. The most complete edition of his works, with the *éloges* by D'Alembert and Villemain, is that by Dalibon (8 vols., Paris, 1827).

MONTEVERDE, CLAUDIO, an Italian composer, born in Cremona about 1565, died in Venice in 1649. He composed both secular and ecclesiastical music, but was particularly celebrated for his motets and madrigals, of the

latter of which he produced 5 books. Among the improvements which he introduced into music was the employment of double discords; and he also was one of the first, if not the first, to give attention to recitative. In his secular productions, by quitting ecclesiastical modulation, he determined the key of each movement, smoothed and phrased the melody, and made all the parts assimilate more naturally and pleasingly than had been done by any of his predecessors. In his 5th book of madrigals he attempted almost every species of discord and modulation.

MONTEVIDEO, the capital of Uruguay, South America, situated on the N. shore of the estuary of the Rio de la Plata, 130 m. E. S. E. from Buenos Ayres, in lat. 34° 58' S., long. 56° 15' W.; pop. 15,000. It is built on a gentle elevation, at the extremity of a small peninsula, and is surrounded by a strong wall, mounted with guns, and further defended by a citadel and batteries. It is tolerably well built, the houses being mostly of one story with flat roofs and brick floors. The streets are broad, regular, and well paved. There are no public buildings worthy of notice, except the cathedral. The bay of Montevideo is about 4 m. long and 2 broad; it has only from 14 to 19 feet of water, but the bottom is soft, and vessels receive no damage by grounding. It is open to the S. S. W. winds. The harbor presents excellent facilities for building wharfs, docks, &c. All vessels receive and discharge their cargoes by means of launches. The trade of Montevideo is very considerable. The exports consist chiefly of salt beef, hides, hair, tallow, wool, bones, bone ashes, &c.; copper is brought overland from Chili and sometimes shipped here, as well as *maté* or Paraguay tea. The principal imports are cottons, woollens, hardware, flour, wine, spirits, sugar, tobacco, salt, boots, &c. The imports from the United States are flour, chairs, refined sugar, whiskey, cordage, agricultural implements, &c., and chiefly lumber from New York, Boston, and Philadelphia. Scarcely a vessel arrives from the United States without having more or less of lumber on board. From Jan. 1 to Oct. 1, 1859, more than 12,000 dozen American chairs were sold at Montevideo, and other American manufactures are also steadily increasing in demand. A large trade in wool, hair, &c., also exists between Montevideo and the United States. The weather, in the winter months of June, July, and August, is at times boisterous, and the air keen and piercing. In summer the heat is oppressive. The climate, however, is represented as being on the whole pleasant and healthful, though moist. The soil in the neighborhood is fertile, and vegetable productions are abundant. Flesh and fish are cheap. Water is scarce, and can only be obtained from wells dug on the sea shore, or by collecting the rain water in cisterns. Montevideo has steam communication with Rio Janeiro, subsidized by the government of Brazil, and with England by British steamers. The differential

duties so long enforced by the government of the Argentine confederation against Montevideo have been removed since Aug. 1, 1859. The U. S. consul, in his official report of Sept. 30, 1859, says: "Montevideo wants nothing but peace to become the commercial emporium of the river Plate. Its natural position, the splendid back country of which it is the capital, and its fine harbor, all point it out as the true commercial centre of the Rio de la Plata."

MONTEZUMA (Mex. *Montecumatin*, the sad or severe man), the name of two emperors of ancient Mexico.—MONTEZUMA I., the greatest of the Mexican monarchs, ascended the throne in 1486 or 1488. Soon after his accession he made war upon the kingdom of Chalco in defence of his allies the Tezcucans. The Chalcos were routed in a great battle, and their chief city was entirely destroyed. A war followed with the king of Tlatelolco, who was defeated and killed. Montezuma next carried his arms to the southward and conquered the province of Cuixtlan, and subsequently that of Tzompahuacan. In a war with Atonaltzin, a chief of the Mixtacas, he suffered reverses which led to a confederacy between Atonaltzin and the Huexotzincas and Tlascalans against the Mexicans; but Montezuma in his first encounter with the allied army gained a signal victory, and greatly enlarged his empire by annexing the territories of the vanquished. In 1457 he conquered Cuertlactlan, a province on the coast of the Mexican gulf, and carried 6,200 of the people prisoners to Mexico, where they were sacrificed to the god of war. After a successful reign of about 35 years, Montezuma died in 1471.—MONTEZUMA II., the last of the Aztec emperors, born about 1480, succeeded his uncle Ahuitzotl in 1502, and was killed June 30, 1520. He was both a soldier and a priest, and had taken an active part in the wars of his predecessor. As a priest he was distinguished for gravity, reserve, and apparent humility. When his election to the imperial dignity was announced to him, he was employed in sweeping the stairs of the great temple of Mexico. He wept at the address which was made to him by the chief of the deputation to inform him of his elevation, and declared himself unfit for so responsible a station. At the commencement of his reign he displayed energy and enterprise. He led a successful expedition against a rebel province, and brought back a multitude of captives to be sacrificed at his coronation, which was performed with extraordinary pomp. For several years he was constantly engaged in war, and his campaigns, which extended as far as Nicaragua and Honduras, were generally successful. He made important changes in the internal administration of the empire, especially in the courts of justice, and soon became noted for the strictness and severity with which he enforced the execution of the laws. He was also distinguished for munificence to those who served him, and in his expenditures for the embellishment of the capital by the construction

of temples, aqueducts, and other public works. He became equally noted also for arrogance and for the pomp and luxury in which he lived. His profuse expenditures required additional and heavy taxes upon the people, which led to many revolts; and during the latter part of his reign the forces of one half of the empire were constantly occupied in suppressing the rebellions of the other. At the time of the arrival of Cortes in Mexico in 1519, Montezuma was agitated and alarmed not only by the internal troubles of his empire, but by the appearance of several comets, of other strange lights in the sky, and of mysterious fires in the great temple, which the astrologers and seers of Mexico interpreted as omens of the approaching downfall of the empire. Disheartened by these presages, he did not meet the invasion of the Spaniards with his usual energy. He temporized and wavered, at first forbidding the white men to approach his capital, and then sending an embassy to welcome them. Cortes entered Mexico Nov. 8, 1519, and was received by Montezuma at last with courtesy and apparent good will. His personal appearance at their first interview is thus described by Prescott: "Montezuma wore a girdle and ample square cloak, *tilmatli*, of his nation. It was made of the finest cotton, with the embroidered ends gathered in a knot round his neck. His feet were defended by sandals having soles of gold, and the leathern straps which bound them to his ankles were embossed with the same metal. Both the cloak and sandals were sprinkled with pearls and precious stones, among which the emerald and the *chalchihuitl*—a green stone of higher estimation than any other among the Aztecs—were conspicuous. On his head he wore no other ornament than a penach of plumes of the royal green, which floated down his back, the badge of military rather than of regal rank. He was at this time about 40 years of age. His person was tall and thin, but well made. His hair, which was black and straight, was not very long; to wear it short was considered unbecoming persons of rank. His beard was thin, his complexion somewhat paler than is often found in his dusky, or rather copper-colored race. His features, though serious in their expression, did not wear the look of melancholy, indeed of dejection, which characterizes his portrait, and which may well have settled on them at a later period. He moved with dignity, and his whole demeanor, tempered by an expression of benignity not to have been anticipated from the reports circulated of his character, was worthy of a great prince. Such is the portrait left to us of the celebrated Indian emperor, in this his first interview with the white men." Cortes at first treated the emperor with the greatest deference, but a collision between the Mexicans and a Spanish garrison at Vera Cruz soon afforded him a welcome pretext for a change of measures. At the end of a week after his arrival in Mexico, he waited on Montezuma with a few of his officers under the pretence of a friendly visit, and, after upbra-

ing him with the transactions at Vera Cruz, took him captive in his own palace and carried him to the Spanish head-quarters. The terrified emperor, fearing instant death if he made any opposition, assured his astonished subjects, who were about to attempt a rescue as he passed through the streets in custody of the strangers, that he accompanied the Spaniards of his own free will. Shortly after his arrest, Montezuma was for a while put in irons, and was so completely humbled by the treatment he received that when Cortes, deeming his spirit sufficiently broken, offered to liberate him, he declined to return to his palace, apparently ashamed to be seen by his nobles. He was subsequently induced to swear allegiance to the king of Spain, and was kept a prisoner for 7 months, till in June, 1520, the people of the capital rose in insurrection and besieged the Spaniards in their quarters. He was induced by Cortes to address his subjects from the battlements of his prison in hopes of appeasing the tumult; but though at first listened to with respect, his appeals in behalf of the white men at length exasperated the Mexicans, and a shower of missiles was discharged at him, one of which, a stone, struck him on the temple with such force that he fell senseless. The unhappy monarch, more affected by the degradation of his situation than by the wound itself, never recovered from this blow. He refused all remedies, tore off the bandages as often as they were applied, rejected all nourishment, and died in a few days. "The tidings of his death," says the chronicler Bernal Diaz, "were received with real grief by every cavalier and soldier in the army who had had access to his person; for we all loved him as a father—and no wonder, seeing how good he was." Some of the children of Montezuma became Christians, and were carried to Spain, and from them were descended the counts of Montezuma, one of whom was viceroy of Mexico from 1697 to 1701.

MONTFAUCON, BERNARD DE, a French Benedictine monk, born in Soulage, Languedoc, Jan. 17, 1655, died Dec. 19, 1741. After completing his education at the college of Limoux, he served in two campaigns in Germany under Turenne. Grief for the sudden death of his parents induced him, in 1675, to enter a Benedictine convent at Toulouse. Afterward he went to Paris, where he became a member of the congregation of St. Maur, and acquired a high reputation for his scholarly attainments. In 1719 he was made a member of the academy of inscriptions. His most important works are: *Palæographia Græca, sive de Ortu et Progressu Literarum Græcarum* (fol., Paris, 1708); *L'antiquité expliquée et représentée en figures* (in French and Latin, 10 vols. fol., 1719); and *Les monuments de la monarchie Française* (in French and Latin, 5 vols. fol., 1729-'88). He also published valuable editions of the works of several of the Greek fathers.

MONTFERRAT, a territory of Sardinia, formerly an independent duchy, between Milan, Piedmont, and Genoa, and separated by a strip

of Milanese territory into the divisions of Casale on the N. and Acqui on the S., Casale being the capital. It often changed masters, and was for more than a century in the hands of the dukes of Mantua; but in 1703 it was bestowed by the emperor Leopold I. upon the duke of Savoy, a possession of whose house it has since remained. The family of Montferrat was of remote origin, and very conspicuous in the middle ages.

MONTFORT, JEAN (IV.) DE, duke of Brittany, born in 1293, died in Hennebon, Sept. 26, 1345. He was the son of Duke Arthur II., and succeeded his brother Jean III. in 1341. The latter had bequeathed the duchy to Charles of Blois, the husband of his niece; but Montfort found little difficulty in getting possession, and Charles complained to the king, Philip of Valois, who sent an army under his son the duke of Normandy to besiege the usurper in Nantes. In order to spare the city from assault, Montfort surrendered and was carried prisoner to Paris; but in the mean time his wife, Jeanne of Flanders, put herself at the head of his partisans and withdrew to Hennebon, where she defended herself heroically against the forces of Charles, on one occasion repelling a furious assault in person at the head of 300 cavaliers. The arrival of auxiliaries sent by Edward III. of England, to whom Montfort had done homage for Brittany, obliged Charles to raise the siege. A second attempt upon the same city in 1342 was equally unsuccessful, and Charles soon lost successively Guérande, Vannes, Carhaix, and Quimperlé. In the same year Edward III. arrived in France with fresh troops and advanced to Rennes, where Philip marched out to meet him. It seemed likely that the quarrel for a single duchy would become a war between two kingdoms, when by the mediation of the pope a truce was concluded between the monarchs, and the Bretons were left to fight out their own battles. Montfort's party, which before was barely a match for his rival's, had grown during his imprisonment, and Philip still further increased it by putting to death 15 Breton nobles whom he believed to have favored the English. Montfort himself escaped in disguise in 1345, and went to England, whence he soon returned with troops and made an unsuccessful attempt upon Quimper. He then retired to Hennebon, where he died a few weeks afterward, leaving a son who continued the war with Charles, and became duke as Jean V.

MONTFORT. I. SIMON DE, a French soldier, born about the middle of the 12th century, slain in 1218. He early distinguished himself by piety, physical strength, and valor. He engaged in the 4th crusade, under Baldwin of Flanders and the marquis of Montferrat; but when he saw the enterprise diverted from its legitimate object, he declined to follow its chiefs to Constantinople, and to fulfil his vows went by himself to Palestine. On his return home he took up arms again at the summons of Pope Innocent III., and in 1208 was elected the leader of the holy war waged against the Albigenses of

southern France, whom he mercilessly pursued and slaughtered. On the taking of Béziers, no fewer than 15,000 of its inhabitants were put to death by his permission, if not by his orders. Carcassonne was scarcely better treated; the viscount of Béziers, who commanded there, was made prisoner in an interview for negotiation; the town was consequently forced to surrender, and many of its citizens were sentenced to death as heretics. At Lavaur, Aimery of Montreal was hanged, 80 knights were put to the sword, hundreds of poor people burned at the stake, and the lady of the castle, Aimery's sister, was thrown alive down a well, and stones were heaped over her. Montfort ruled despotically over the territories which he had wrested from Count Raymond of Toulouse in this war; and when Don Pedro II., king of Aragon, came to protect the latter, as his lord paramount, the crusader met him, Sept. 12, 1213, and defeated him under the walls of Muret; the unfortunate prince was killed during the battle by several knights who had conspired to take his life. Montfort was proclaimed count of Toulouse, and retained his usurped honors for several years. Raymond's son finally managed to reënter Toulouse, where he had many adherents; Montfort besieged that city with all his forces, but met with unexpected resistance. At the end of 8 months, when attempting to storm it, he was killed on the spot by a large stone thrown by machinery from the wall. His elder son, Amaury, succeeded him as count of Toulouse, afterward exchanged this title for the dignity of grand constable of France, and died in 1241 on his return from Palestine. II. SIMON DE, earl of Leicester, younger son of the preceding, the leader of the English barons in the reign of Henry III., born about the end of the 12th century, killed Aug. 4, 1265. Having gone to England to escape the enmity of Blanche of Castile, queen regent of France, he gained the favor of the king, who bestowed upon him the earldom of Leicester, the governorship of Gascony, and the hand of his own sister Eleanor, countess dowager of Pembroke. He governed Gascony with an iron hand, and made his power particularly felt by the native lords, but was popular with the English. This gave him considerable influence in his adopted country, where he played a conspicuous part in the political troubles that followed. He became the head of the barons who conspired to curtail the king's prerogative. Henry III. having in 1258 convoked a parliament, he appeared in arms with his confederates, and constrained the king to sign those remarkable regulations called the provisions of Oxford, by which the whole legislative and executive power was thrown into the hands of 24 barons, who were in fact controlled by Montfort. An agreement was proposed between the nobles and the king through the arbitration of Louis IX. of France; but the award of this prince not being acceptable to the former, both parties took arms. In May, 1264, Leicester met the royal army at Lewes in Sussex, and a fierce

engagement terminated in its total defeat and the capture of the king. In Jan. 1265, he summoned a parliament, in which, for the first time on record, representatives of boroughs were admitted. His power was now at its height, but his overbearing conduct excited discontent even among the adherents of the national cause, and the king's son, Prince Edward, who was kept as a hostage, having made his escape, many of his former opponents joined his standard. Leicester now vainly attempted resistance; he was hemmed in at Evesham by superior numbers; he fought with the courage of despair, but was slain with one of his sons and many barons, while his army was completely routed. The family of Montfort was expelled from England. Notwithstanding his faults, he had founded his popularity on so solid a basis that it outlived his overthrow and death; although under sentence of excommunication, he was almost honored as a saint, and miracles were reported to be wrought at his tomb.

MONTGOLFIER. See AEROSTATION.

MONTGOMERIE, ARCHIBALD WILLIAM. See EGLINTON AND WINTON, earl of.

MONTGOMERY, the name of counties in 16 of the United States. I. An E. co. of N. Y., intersected by the Mohawk river, which is here joined by the Schoharie river and other smaller streams; area, 856 sq. m.; pop. in 1855, 30,484. It has a fertile soil, especially in the valley of the Mohawk. The productions in 1855 were 42,888 bushels of wheat, 997,605 of oats, 347,516 of Indian corn, and 34,582 tons of hay. There were 48 saw mills, 24 grist mills, 15 tanneries, 5 newspaper offices, 118 school houses, and 52 churches. The Erie canal and the New York central railroad pass through the county. Capital, Fonda. II. A S. E. co. of Penn., bounded S. W. by the Schuylkill river; area, 450 sq. m.; pop. in 1850, 58,291. The surface is undulating, and the soil is rich, especially along the Schuylkill. The productions in 1850 were 878,244 bushels of Indian corn, 309,255 of wheat, 699,824 of oats, 238,924 of potatoes, 98,701 tons of hay, and 2,044,089 lbs. of butter. There were 117 flour and grist mills, 87 lime kilns, 21 iron mines, 16 manufactories of cabinet ware, 9 of farming implements, 16 brick yards, 11 cotton factories, 7 woollen factories, 4 iron furnaces, 4 forges, 5 powder mills, 2 rolling mills, 16 linseed oil mills, 19 tanneries, 95 churches, 6 newspaper offices, and 9,998 pupils attending public schools. Limestone and marble are found in the S. E. and iron, lead, and copper in the W. The Philadelphia and Norristown, the Chester Valley, and the Philadelphia, Easton, and Water (two) railroads pass through the county. Capital, Norristown. III. A central co. of Md., bounded N. E. by the Patuxent and S. W. by the Potomac river; area, 440 sq. m.; pop. in 1850, 15,682, of whom 5,114 were slaves. The surface is moderately uneven; the soil is fertile along the banks of the rivers. The productions in 1850 were 896,947 bushels of Indian corn, 164,108 of wheat,

168,240 of oats, 8,588 tons of hay, and 426,995 lbs. of tobacco. There were 4 woolen factories, 31 grist mills, 37 churches, 1 newspaper office, and 750 pupils attending public schools. The Chesapeake and Ohio canal passes along the S. W. border. Capital, Rockville. IV. A S. W. co. of Va., bounded W. by New river, and drained by the head waters of Staunton river; area, 490 sq. m.; pop. in 1850, 8,359, of whom 1,471 were slaves. The surface is mountainous, and the soil generally rocky, but productive near the rivers. The productions in 1850 were 266,616 bushels of Indian corn, 51,827 of wheat, 106,120 of oats, and 4,453 tons of hay. There were 4 saw mills, 5 tanneries, 12 churches, and 850 pupils attending public schools. Value of real estate in 1856, \$2,650,812, showing an increase of 80 per cent. since 1850. The Virginia and Tennessee railroad passes through the county. Capital, Christiansburg. V. A S. co. of N. C., bounded W. by Yadkin river and drained by its branches; area, 500 sq. m.; pop. in 1850, 6,872, of whom 1,773 were slaves. The surface of the W. part is hilly; much of the soil is fertile. In 1850 this county produced 192,191 bushels of Indian corn and 1,456 bales of cotton. There were 2 cotton factories, 8 saw mills, 6 churches, and 1,022 pupils attending public schools. Capital, Lawrenceville. VI. A S. E. co. of Ga., bounded N. E. by Pendleton's river, S. by the Altamaha, and S. W. by the Little Ocmulgee, and intersected by the Oconee; area, 624 sq. m.; pop. in 1859, 2,843, of whom 784 were slaves. The surface is level and the soil sandy. The productions in 1850 were 55,165 bushels of Indian corn, 28,710 of sweet potatoes, and 292 bales of cotton. There were 13 churches, and 200 pupils attending public schools. Capital, Mount Vernon. VII. A S. E. co. of Ala., bounded N. W. by the Coosa and Alabama rivers, and intersected in the N. by the Tallapoosa; area, 900 sq. m.; pop. in 1850, 19,795, of whom 19,511 were slaves. The surface is uneven, and the soil generally fertile. The productions in 1850 were 1,265,645 bushels of Indian corn, 293,488 of sweet potatoes, 191,358 of oats, 156,539 lbs. of rice, and 25,326 bales of cotton. There were 20 churches, 10 newspaper offices, and 366 pupils attending public schools. The Montgomery and West Point railroad passes through Montgomery, the capital of the county and of the state. VIII. An E. co. of Texas, drained by San Jacinto river and its tributaries; area, 852 sq. m.; pop. in 1858, 1,946, of whom 1,947 were slaves. It has a rolling surface with an abundance of good timber, and the soil, with the exception of some sandy pine barrens, is fertile. The productions in 1850 were 80,441 bushels of Indian corn, 1,109 bales of cotton, and 89,720 lbs. of butter. There were 8 churches, and 75 pupils attending schools. Value of land in 1859, \$715,892. Capital, Montgomery. IX. A W. co. of Ark., drained by Washita river and its branches; area, 1,050 sq. m.; pop. in 1854, 2,172, of whom 18 were slaves. The surface is mostly moun-

tainous. The productions in 1854 were 108,903 bushels of Indian corn, 5,523 of wheat, 8,867 of oats, and 186 bales of cotton. The county contains excellent slate. Capital, Mount Ida. X. A N. W. co. of Tenn., bordering on Kentucky, and drained by Cumberland river and its branches; area, 500 sq. m.; pop. in 1850, 21,945, of whom 9,071 were slaves. It has a rolling surface and a good soil. The productions in 1850 were 1,077,304 bushels of Indian corn, 153,179 of oats, 43,807 of wheat, 3,454,745 lbs. of tobacco, and 155,129 of butter. There were 27 churches, 4 newspaper offices, and 343 pupils attending schools. Capital, Clarksville. XI. A N. E. co. of Ky., bounded S. in part by Red river; area, 275 sq. m.; pop. in 1850, 9,903, of whom 3,073 were slaves. The surface is hilly and mountainous, and most of the soil very fertile. The productions in 1850 were 914,863 bushels of Indian corn, 97,974 of oats, 106 tons of hemp, 4,410 lbs. of tobacco, and 35,302 of wool. There were 12 grist mills, 1 newspaper office, 19 churches, and 558 pupils attending public schools. Capital, Mount Sterling. XII. A S. W. co. of Ohio, drained by Miami river and its branches; area, 490 sq. m.; pop. in 1850, 38,218. The surface is undulating, and the soil generally fertile and well cultivated. Trenton limestone is abundant. The productions in 1850 were 315,769 bushels of wheat, 1,273,932 of Indian corn, 198,893 of oats, and 12,301 tons of hay. There were 60 churches, 10 newspaper offices, and 13,828 pupils attending public schools. The Miami canal passes through the county, and several railroads terminate at Dayton, the capital. XIII. A W. co. of Ind., drained by Sugar, Big and Little Raccoon creeks; area, 504 sq. m.; pop. in 1850, 18,084. The surface is level or undulating, and the soil is generally good. The productions in 1850 were 1,392,404 bushels of Indian corn, 121,988 of wheat, 99,088 of oats, 10,714 tons of hay, and 85,233 lbs. of wool. There were 19 saw mills, 24 grist mills, 48 churches, 2 newspaper offices, and 1,880 pupils attending schools. The New Albany and Salem railroad passes through Crawfordsville, the capital. XIV. A S. W. co. of Ill., drained by Shoal creek and its branches, and the head waters of the Macoupin creek; area, 544 sq. m.; pop. in 1855, 9,041. It has a diversified surface, partly covered with forests, and a rich soil. The productions in 1850 were 452,885 bushels of Indian corn, 98,412 of oats, 21,425 of wheat, and 18,858 lbs. of wool. There were 25 grist mills, 12 churches, and 1,663 pupils attending public schools. The Alton and Terre Haute railroad passes through Hillsborough, the capital. XV. An E. co. of Mo., bounded S. by the Missouri river and drained by Au Quivre and Lantre creeks; area, 576 sq. m.; pop. in 1856, 7,263, of whom 1,245 were slaves. The surface is hilly in the region of the river, and in other parts undulating; the soil is of various qualities. Limestone, iron ore, and coal are found. The productions in

1850 were 344,721 bushels of Indian corn, 21,170 of wheat, 74,953 of oats, 1,009 tons of hay, 20,696 lbs. of wool, and 353,865 of tobacco. There were 9 churches, and 692 pupils attending public schools. Capital, Danville. XVI. A S. W. co. of Iowa, drained by Nishnabotona and West Nodaway rivers, tributaries of the Missouri; area, 432 sq. m.; pop. in 1859, 1,094. The surface is undulating and the soil fertile. The productions in 1859 were 66,455 bushels of Indian corn, 1,112 of wheat, 4,488 of potatoes, and 19,887 lbs. of butter. Capital, Frankford.

MONTGOMERY, a city of Montgomery co., Ala., and capital of the state and county, situated on a high bluff on the left bank of the Alabama river, 415 m. above Mobile; pop. in 1850, 4,935; in 1858 estimated at 7,000, and in 1860 at 10,000. In addition to the state house, gaol, and various public offices, it has 6 churches, several seminaries, the law department of the university of Alabama, 4 daily newspaper offices, 2 banks, and several marble yards, iron foundries, and saw mills, and is largely engaged in the shipment of cotton. The river is navigable by steamboats to this point at all seasons of the year. The Alabama and Florida railroad connects the city with Pittston, and when completed will extend to Pensacola; and the Montgomery and West Point railroad, which now (1860) has its W. terminus at Montgomery, is to be prolonged by means of connecting lines to the Mississippi. Montgomery was laid out in 1817, and the seat of government was removed to it from Tuscaloosa in 1846.

MONTGOMERY, Countess. See **BAUER, KAROLINE**.

MONTGOMERY, JAMES, a British poet, born in Irvine, Ayrshire, Nov. 4, 1771, died near Sheffield, April 30, 1854. His father was a Moravian preacher, and James, being intended for the same office, was sent in his 7th year from Ireland, whither his father had removed, to a Moravian settlement at Fulneck, near Leeds, Yorkshire, to complete his education. Here he remained for 10 years, undistinguished except for indolence and melancholy. At the end of that period, his parents being now dead, the brethren at Fulneck apprenticed him to a grocer in Mirfield. He was already a writer of verses, a love of poetry having been awakened in him by hearing Blair's "Grave" read aloud; and before the age of 14 he had written a mock heroic poem of 1,000 lines, and had commenced an epic to be called "The World." The servitude of a grocer's shop becoming irksome to him, he ran away in June, 1789, with 8s. 6d. in his pocket; but after many wanderings he engaged again as shop boy in Wath, a village of Yorkshire. When he had been in this place a year he sent a volume of manuscript poetry to Mr. Harrison, a London publisher, and soon after went there himself. Mr. Harrison refused his poems, but engaged him as his shopman. In London he led the same recluse life as in the country; writing was his only amusement, and

in 1792 his first publication, a tale, appeared in an Edinburgh periodical. But he soon tired of London, and returned to Wath, where however he remained only for a short time. Toward the end of 1792 he became clerk to Mr. Joseph Gales of Sheffield, editor and publisher of the "Sheffield Register," a newspaper accused of revolutionary tendencies. He wrote political articles, and when Gales, learning that a warrant had been issued against him for treason, fled to America, Montgomery started a new weekly journal called the "Sheffield Iris," advocating peace and reform principles. The first number appeared July 4, 1794, and he continued to edit it till Sept. 27, 1825, when on his retirement a public banquet was given him by his townsmen. Almost immediately after the first appearance of the "Iris," he was indicted, tried, and fined £20, and sentenced to 3 months' imprisonment, for printing a doggerel ballad on "The Fall of the Bastille" for a poor hawker. Arriving in 1796 he was found guilty of sedition, fined £30, and sentenced to 6 months' imprisonment for publishing in his newspaper an account of a riot in Sheffield, to quell which the military had been called out and had fired on the people. He was confined in York castle, where he wrote a small volume of poems entitled "Prize Amusements," published in 1797. His gentle yet earnest character, and his literary ability, now began to be recognized, and won him the regard of his political opponents. Many short poems appeared in the "Iris," and he began to take a high rank as a sacred poet. In 1806 he published "The Wanderer in Switzerland," which soon reached a 8d edition. "The West Indies," a descriptive poem, commemorative of the abolition of the slave trade, appeared in 1809. Soon after he published "The World before the Flood," and "Greenland," celebrating the efforts of the Moravian missionaries in that country. The former poem attained great popularity. In 1827 appeared "The Pease Island and other Poems." A collected edition of his works was called for in 1836, and again in 1849 and in 1851. In 1853 "Original Hymns for Public, Private, and Social Devotion" concluded the series of his poetical works. His prose works are: "Prose by a Poet," being two volumes of sketches, and a "History of Missionary Enterprise in the South Seas." He delivered in 1830 a course of lectures on the "History of English Literature," and in 1852 a lecture "On some Passages of English Poetry but little known." In 1835 he declined the office of professor of rhetoric in the university of Edinburgh, and in the same year a pension of £150 was bestowed on him by the queen. Though he was a politician and journalist, and the larger part of his poetry is hardly religious, yet he is best known by that in which he succeeded best, his sacred hymns. They have a pure, affecting and often profound religious spirit. His style is considered a model of clearness and simplicity. In politics he was a liberal whig, and an ardent slavery abolitionist, and in his manhood

reunited himself with the Moravians. Memoirs of his life and writings, with extracts from his correspondence and journals (7 vols. 8vo., 1855-'6), have been published by two of his friends, John Holland and James Everett. A complete edition of his poetical works appeared in 1855 (4 vols. 12mo., London).

MONTGOMERY, RICHARD, an American revolutionary general, born at Convoy House, near Raphoe, Ireland, Dec. 2, 1736, killed in the attack on Quebec, Dec. 31, 1775. At the age of 18 he obtained a commission in the British army, in 1757 commenced his career of active service in America, and at the siege of Louisburg in 1758 and elsewhere gave evidence of high military capacity. He distinguished himself in the expeditions against Martinique and Havana, and in 1768 obtained permission to revisit Europe, where he remained during the next 9 years. He then sold out his commission, and, emigrating to New York, married a daughter of Judge Robert R. Livingston, and in 1773 settled in Rhinebeck, Dutchess co. In 1775 he represented Dutchess co. in the provincial congress, and later in the same year was appointed one of the 8 brigadiers to serve in the newly organized army of the united colonies. The office, which had been neither expected nor desired by him, was accepted on the ground that "the will of an oppressed people, compelled to choose between liberty and slavery, must be obeyed." He was immediately attached, as senior brigadier, to the larger of the two divisions sent to Canada in the summer of 1775, and in the early part of September found himself before the fortress of St. John's. The illness of Gen. Schuyler having caused his return to Albany, Montgomery assumed the command of the division, and by a series of well directed movements successively acquired possession of Ohambly, St. John's, and Montreal, thereby becoming in the middle of November master of a great part of Canada. Effecting a junction on Dec. 4 with Arnold's troops, then recently arrived, he immediately proceeded to take a position before Quebec. At a council of officers it was determined to attempt to capture the place by a *coup de main*, and two attacks of this character were projected, the one on the lower town from the suburbs of St. Roque, and the other on the upper at the Cape Diamond bastion, "to be executed in the night and when the weather should be favorable." Accordingly, on Dec. 31, at 2 A. M., the storming columns commenced their march amid a heavy fall of snow, which considerably impeded their movements. Montgomery, who headed the attack on the Cape Diamond bastion, reached with difficulty the first barrier, which was rapidly carried. Pausing a moment to encourage his men, he pressed eagerly on to the second barrier, and with his two aids fell dead at the first and only discharge by the British artillerymen, who immediately took to flight. His men, panic-stricken by the loss of their leader, com-

menced a disorderly retreat, and the assault on the city ended in failure. He was interred within the city walls. His death was considered a severe loss to the American cause, and congress testified "their grateful remembrance, profound respect, and high veneration" for him, by erecting a monument to his memory in the front of St. Paul's church, New York. In 1818 the state of New York caused his remains to be removed and placed beneath the monument.

MONTGOMERY, ROBERT, an English poet and clergyman, born in Bath in 1807, died in Brighton, Dec. 8, 1855. He was the son of a theatrical clown named Gomery, but always assumed the more dignified name in his literary works. At an early age he was conducting a weekly publication, called "The Inspector," in his native city. In 1827 he published "The Stage Coach," and in the same year a volume entitled "The Age Reviewed, a Satire." The tone of this poem was religious, and all his subsequent efforts were in the same vein. His next publication, "The Omnipresence of the Deity" (1828), was the most popular of his poems, 8 editions being sold in as many months; and in 1857 it had reached the 26th edition. It was on the appearance of the 11th edition of this work in 1830, that Macaulay wrote a famous criticism upon it in the "Edinburgh Review," charging the poet with plagiarism and every grammatical and rhetorical sin, and ascribing its popularity to a well planned system of puffing. In 1828 he also published a volume containing "A Universal Prayer, Death, a Vision of Heaven, and a Vision of Hell." His next production was "Satan," which procured for him the popular sobriquet of "Satan" Montgomery. In 1830 he entered Lincoln college, Oxford, with the intention of preparing himself for the ministry; and in 1831 he published "Oxford," a semi-historical poem, with notes and illustrations, which gained him however only ridicule among the members of the university. In 1832 he published "The Messiah, a Poem, in Six Books;" and in 1833 "Woman, the Angel of Life." In 1835 he was ordained, and his first curacy was Whittington in Shropshire. In May, 1836, he became minister of Percy street chapel, London, whence in 1838 he went to St. Jude's chapel, Glasgow. Here his preaching being attended with much controversy, he resigned and returned to London in 1842. Immediately on his arrival he published "Luther, or the Spirit of Toleration;" and in the next year resumed his ministry at Percy street chapel, where he continued until his death. From 1843 to 1854 he issued a number of theological works, and a series of "Meditations" upon Scripture subjects; "Sacred Meditations and Moral Themes;" "The Christian Life, a Manual of Sacred Verse;" "Lyra Christiana—Poems on Christianity and the Church;" "Lines on Wellington," and "The Hero's Funeral," in 1852; and "The Sanctuary, a Companion in Verse for the English Prayer Book."

MONTGOMERYSHIRE, a county of Wales, bounded N. by Denbighshire, E. by Shropshire, S. by Radnorshire, S. W. by Cardiganshire, and W. and N. W. by Merionethshire; area, 755 sq. m.; pop. in 1851, 67,835. It belongs almost entirely to the basin of the Severn, which traverses its whole extent. The principal mountains are Plinlimmon, the Breiddin hills, and Llandinam, which is 1,895 feet high. The chief rivers, beside the Severn, are the Vyrnwy, Wye, and Dovey. The soil of the low country is in general fertile. In the districts bordering on England agriculture has made considerable progress. Copper, zinc, coal, and limestone are mined. The staple manufactures are flannels, and a species of cotton called "Welsh plains." Montgomeryshire sends two members to parliament, one for the county and one for 6 united boroughs. Capital, Montgomery.

MONTH (Sax. *mona*, the moon), a period of time defined, according to the derivation of the word, by one revolution of the moon around the earth, and hence equal to 29 days, 12 hours, 44 minutes, and 3 seconds. This division of time, now known as the lunar month, was used by the Chaldeans and Egyptians, and is still by the Jews, Turks, and many uncivilized nations, as the most distinctly marked period of the year. But if the year be made to comprise 12 of these months, the seasons will soon be found to fall back from those months to which they originally belonged, so that in 84 years the change would be complete from summer to winter. The period of a month has consequently been changed to the 12th part of the solar year, and comprises an average length of 30 days, 10 hours, and 30 minutes. This is called the solar month. But the calendar months are not equal divisions of the year, some (April, June, September, and November) consisting of 30, and the remainder of 31 days, except February, to which a period of only 28 days is assigned, with the addition every 4th year of one more day. These distinctions often give rise to much confusion as to the time intended to be designated by a month. In popular language it is often understood to be 4 weeks, as this is very nearly an equal period, expressed in the division by weeks, to the month. This is even laid down by Blackstone as the legal definition of the term, so that a lease for 12 months is only for 48 weeks; but the expression "a twelvemonth" has been legally held to mean a solar year.

MONTHOLON, CHARLES TRISTAN DE, count of Lee, a French soldier, born in Paris in 1783, died in Aug. 1853. He belonged to an ancient family, entered the naval service when 10 years old, but soon left it, and in 1797 became a non-commissioned officer in a regiment of cavalry. By his bravery and good conduct, in less than 3 years he reached the rank of *chef d'escadron*. In this capacity he evinced great zeal in behalf of Bonaparte on the 18th Brumaire, after which he was officially attached to the first consul's staff, and gained promotion by his valor during the campaigns in Italy, Germany, and

Poland, especially distinguishing himself as aide-de-camp to Berthier, in the battle of Wagram, where he received 5 wounds. In 1806 he was appointed chamberlain to the emperor, was intrusted with several diplomatic missions which he discharged with tact and ability, and was made a brigadier-general in 1814. The fall of Napoleon afflicted him greatly; he pleaded in vain to accompany the emperor to Elba, was among the foremost to join him on his return; in 1815, acted as his aide-de-camp during the Hundred Days, fought for him to the last, and on his second abdication obtained permission to follow him to St. Helena, where he devoted himself to his personal service. He witnessed his death, was appointed one of his executors, and returning to Europe, published in conjunction with Gen. Gourgaud a series of papers written under Napoleon's dictation: *Mémoires pour servir à l'histoire de France sous Napoléon, et à la vie à Ste. Hélène sous sa dictée* (8 vols. 8vo., Paris 1823). His fortune having been ruined by his protracted absence, he tried to retrieve it by commercial enterprise, but failed, and became involved in debt. He accompanied Prince Louis Napoleon in his unsuccessful attempt at Belgium in 1840, and was sentenced to share his imprisonment at Ham, but at the end of a few years received a pardon. While in prison he wrote *Histoire de la captivité de Ste. Hélène* (Paris 1846). After the revolution of 1848 he became a member of the legislative assembly, and lived long enough to see Louis Napoleon, to whose fortunes he was as enthusiastically devoted as he had been to those of his uncle, ascend the imperial throne.—His son, the marquis of Montholon, who has married a lady of Virginia, was (1860) French consul-general in New York.

MONTHYON, or **MONTHYON**, ANTOINE JEAN BAPTISTE ROBERT AUGER, baron de, a French philanthropist, born in Paris, Dec. 23 or 24 1733, died there, Dec. 26, 1820. He was successively intendant of the provinces of Provence, Auvergne, and Anjou, and as member of the council opposed the unlawful proceedings resorted to in the case of Lachalotais, and protested against the dissolution of ancient parliaments decreed by Chancellor Maupeou. In consequence of this latter act he was deprived of his office. Soon after the accession of Louis XVI he was appointed councillor of state, became in 1780 chancellor of the count d'Artois (afterward Charles X.), emigrated to England on the breaking out of the French revolution, and did not return to France until the second restoration. He possessed a princely fortune, and devoted the larger portion not of his income, but of his capital, to philanthropic purposes. He generously assisted his exiled countrymen, and bequeathed to French hospitals over 200,000 francs. As early as 1782 he had founded a prize for virtue and several other prizes to be awarded by the French academy and the academy of sciences. These, having been suppressed by order of the convention, were renewed by the donor on his return to France in 1814.

and afterward increased. Every year the French academy distributes two Monthyon prizes of 10,000 francs each: one to the poor person who has performed the most meritorious deed of virtue; the other to the author of the work which has been judged the most useful for the improvement of public morals. Two others of equal amount are awarded by the academy of sciences: one to him who shall have found during the year some means of improvement of the medical and surgical art; the other to him who shall have discovered the means of rendering some mechanical art less unhealthy. Monthyon wrote an *Éloge du chancelier de l'Hôpital* (1777); *Recherches et considérations sur la population de la France* (1778); an essay on the influence of the discovery of America upon Europe, which won a prize at the French academy; *Quelle influence ont les diverses espèces d'impôts sur la moralité, l'activité et l'industrie des peuples?* (1808); *Les ministres des finances en France de 1660 à 1791* (London, 1812); *État actuel du Tonkin* (London, 1812), &c. A poem in his honor by Alfred de Wailly (1826), and a prose essay by L. Feugère (1834), were crowned by the French academy in 1884.

MONTI, VINCENZO, an Italian poet, born in Busignano, near Ferrara, Feb. 19, 1754, died in Milan, Oct. 18, 1828. He was originally destined by his father to the career of an agriculturist; but while at the seminary of Casenza he displayed such aptitude for study and love of literature that he was sent to the university of Ferrara. He aimed at no profession, but read with enthusiasm the Latin and Italian poets, and before his 16th year published Latin elegies and an Italian poem on the prophecy of Jacob. The influence of Dante, whom he made his model, appears in the sublime imagery of his "Vision of Ezekiel," written 2 years later. His occasional verses attracted the attention of Cardinal Borghese, who conducted him to Rome, where he was associated with the most eminent men, and appointed secretary to Braschi, nephew of Pope Pius VI. Assuming the clerical habit, he was called the Abbate Monti, though he never took orders. He excited and published several poems with applause, and was received into the academy of Arcadians, with the principal members of which he was soon at war on account of his satires and impatience of criticism. Alfieri was at his time gaining his first successes in tragedy, several of his plays having been privately performed. Monti attempted to rival the excellence of his *Virginia* by producing a drama entitled *Aristodemo*, in which he aimed to combine the vigor of Alfieri with greater smoothness and elegance. It was favorably received, though severely criticized for its slight action and its horrible plot. A second dramatic attempt, *Galeotto Manfredi*, in which he violates his own principles of classicality, proved a failure. The assassination of the French revolutionary ambassador Basseville in the streets of Rome was the occasion of his next production.

He was selected by members of the pontifical government to celebrate this event in a poem conformed to their political views, and published in 15 days his *Basvilliana*, in a style more truly Dantesque than any thing that had been written for centuries. The angel of the Lord and the enemy of mankind contend for the soul of the murdered republican, which, though finally saved, is doomed for a period to hover on the banks of the Seine and to witness the atrocities of the reign of terror. It was the first effective expression of the horror of monarchical and Catholic Europe at the French revolution. The first edition of his mythological poem *Musogonia* (1796) was agreeable to the papal government; but he afterward embraced the hopes of national revival offered by Bonaparte, whom he made the hero of the second edition (1798), and also of a still finer poem entitled *Prometeo*. He was successively secretary of the directory of the Cisalpine republic and commissary in the Romagna; and Bonaparte, having listened at a private entertainment to one of his poems in honor of revolutionary liberty, pronounced him one of the greatest of Italian geniuses. He fled to France on the Austro-Russian invasion in 1799, but returned to Milan after the battle of Marengo, and published the tragedy of *Caio Graccho*, and a poem on the death of his friend the mathematician Mascheroni. Appointed professor of belles-lettres in the college of Milan, he was immediately afterward promoted to the chair of rhetoric in the university of Pavia. He celebrated the coronation of Napoleon as king of Italy (1805) in the poem of *Il beneficio*, the triumph of Jena in an ode on the *Spada di Federico*, the usurpation of the Spanish throne in the *Palingenesi*, the second marriage of the emperor in the *Hierogamia*, and the birth of the king of Rome in the *Api Panacride*. He also made a translation of the *Iliad*, which is highly esteemed for elegance and fidelity, though he confessed that he knew nothing of Greek, and had studied Homer only through numerous translators and commentators. It was attacked by Ugo Foscolo and other Hellenists, and defended by Monti. After the loss of his honors by the overthrow of Napoleon, he wrote chiefly in prose, though he consented to compose two short poems in praise of the imperial house of Austria. His principal production was a philological work, in which he assailed the principles of the Della Cruscan, and which gave rise to a warm controversy. As a classicist, Monti may be regarded as the last eminent Italian poet of the old school, and he constantly opposed the romanticists who aimed to modernize the national literature. A complete edition of his works was published in 8 vols. (Bologna, 1828), and a select edition in 5 vols. (Milan, 1832).

MONTIGNY, ROSE CIZOS LEMOINE. See CHÉRI.

MONTIJO, the name of a domain in Estremadura, Spain, which in 1697 was raised to the

rank of a count by Charles II. in favor of Count John of Porto Carrero. The ancestry of the latter was traced to Egidio Bocanegra, a Genoese, who in 1340 assisted Alfonso XI. against the Moors, and who became domiciliated in Spain, after having been promoted by Alfonso to the dignity of admiral and count of Palma. The grandson of Bocanegra assumed the title and rank of the house of Porto Carrero on his marriage with the heiress of that family, and one of his successors assumed the title of count of Teba. A descendant of the latter, the count of Montijo, duke of Penaranda, fought in favor of Napoleon I. during his war with Spain, served with distinction in the French army after the expulsion of the French from Spain, and subsequently became a member of the Spanish senate. He died in 1839, and was the father of the present empress of France. (See EUGÉNIE.)

MONTMORENOY, an E. co. of Canada East, bordering on the St. Lawrence, and drained by the Montmorency and St. Anne rivers; area, 7,465 sq. m.; pop. in 1852, 9,598. It has an uneven surface and fertile soil. The isle of Orleans in the St. Lawrence river is included in the county.

MONTMORENOY, a river of Canada, which runs in a very irregular N. and S. course of about 15 m., first through forests and then over a rocky bed through a cultivated country, until, close to the St. Lawrence, about 8 m. below Quebec, it falls over a precipice some 230 feet high, down which it descends nearly perpendicularly. The breadth of the river is about 50 feet, and the stream of water, except during floods, is of no great magnitude. A few years ago a suspension bridge was erected directly over the cataract; but, the fastenings upon the banks of the river being insufficient, it fell shortly after it was opened, while a farmer with his horse and wagon and two foot passengers were crossing.

MONTMORENOY, a village of France, situated near the forest of the same name, 14 m. N. from Paris; pop. about 2,800. It possesses a fine Gothic church of the 14th century, and near the town is the house called L'Ermitage, which was the property of Mme. d'Épinay, and in which Jean Jacques Rousseau resided for some time. He is said to have written there his *Nouvelle Héloïse*. It was afterward occupied by Grétry the composer, who died there in 1818.

MONTMORENOY, the name of one of the oldest and most illustrious of the French feudal families, deriving its title from the village of Montmorency. Its origin has been traced as far back as the middle of the 10th century, and its members were styled "the first barons of France," or "the first Christian barons." Many of them held high offices, including 6 grand constables, 12 marshals, and 4 grand admirals of France, beside a number of cardinals, grand masters, and knights of all European orders. They more than once intermarried with royal families. Several branches issued from the main stock, two of which established themselves

in the Netherlands. Among their descendants were the count of Horn (Philip II. de Montmorency-Nivelle), who together with Egmont was executed in Brussels by order of the duke of Alva in 1568, and Floris de Montmorency, baron de Montigny, who, according to the recent investigations in the archives of Simancas by M. Gachard, was privately executed by order of Philip II., Oct. 14, 1570, his death having been differently and variously described by previous historians. Another celebrated member of the Flemish branch of the Montmorencys was Marshal Luxembourg. There are 4 or 5 representatives of the name still extant. The chief historical characters belonging to this family are the following: I. ANNE, 1st duke of Montmorency, grand constable of France, born in Chantilly, March, 1493, died Nov. 11, 1567. He was an early friend of the duke of Angoulême, afterward Francis I., and first distinguished himself as a soldier under the reign of Louis XII., in the battle of Ravenna, which was won in 1512 by Gaston de Foix. He followed Francis I. in his first expedition to Italy (1515), and fought bravely at Marignano. In 1521 he evinced great activity and firmness during the siege of Mézières, which was defended by Bayard against the army of the emperor Charles V. For his gallantry in the disastrous battle of Riccio, near Milan, in 1522, he was rewarded by the rank of marshal. When the constable of Bourbon invaded Provence at the head of an imperial force in 1524, Montmorency forced him to raise the siege of Marseilles. In 1525 he was made prisoner at the battle of Pavia; but being ransomed, he participated in the negotiations which ended in the treaty of Madrid (1526). He now became governor of Languedoc and grand master of France, and was intrusted with the management of the finances. His avarice gave dissatisfaction to the Genoese admiral Doria, who broke off his alliance with the king of France and became one of the staunchest supporters of the emperor Charles V. In 1536, an imperial army having again entered Provence, the marshal had waste the country, and by skilfully prosecuting the campaign nearly destroyed the enemy. On this occasion he received the appellation of the "French Fabius," and two years later he was made constable. In 1541 court intrigues caused his disgrace, and he retired to his castle at Chantilly. After the death of Francis I. he returned to court, where his influence became paramount; offices, pensions, and favors of all kinds were bestowed upon him and his relatives, while his baronial estate was erected into a duchy by Henry II. In 1548, the inhabitants of Guienne having revolted on account of an oppressive tax on salt, he went to Bordeaux at the head of 10,000 men, and put down the insurrection with the most cruel severity. In the invasion of Champagne by Duke Philip Emmanuel of Savoy, the celebrated general Philip II., he was sent to oppose him, but his imprudence lost the battle of St. Quentin, Aug. 10, 1557, and was taken prisoner. ANTOINE

his own release, he was instrumental in bringing about in 1559 the disadvantageous peace of Cateau-Cambrésis. During the short reign of Francis II. he lived in retirement; but he played a conspicuous part during the reign of Charles IX., and in concert with the duke of Guise and Marshal St. André, with whom he formed a sort of triumvirate, was an uncompromising enemy of the Huguenots. Having on one occasion broken into their church in the rue St. Jacques at Paris, and ordered his followers to destroy every thing therein, he received the sobriquet of *Capitaine Brûle-banques*. In 1562, at the battle of Dreux, where he shared the command with his two colleagues, he was wounded and taken by the Protestants, but Guise managed to win the day. Released by the peace of Amboise in 1568, he retook Havre de Grâce, which had been seized by the English. He plotted a massacre of the Protestants; but the court would not approve his proposal, and he was consequently sent into retirement at Chantilly. He appeared once more on the stage of public affairs in 1567, when, at the head of the Catholic army, he met the prince de Condé near St. Denis, and fought a drawn battle in which he lost his life. It was ascribed to his faulty plan of operations that his army did not gain a victory. His death was welcome news to Queen Catharine de' Medici and the courtiers, whom he had frequently offended by his overbearing manners. II. HENRI II., 4th duke of Montmorency, grandson of the preceding, born in Chantilly in 1595, executed in Toulouse in 1682. Henry IV. was his godfather, and Louis XIII. appointed him admiral of France before he was 17 years old. He succeeded his father in the governorship of Languedoc, fought against the Protestants, distinguished himself at the sieges of Montauban and Montpellier, and in 1625 conquered the islands of Ré and Oléron. He now sold his office of admiral to Richelieu, who kept it for himself, and was thus enabled to control the operations at the celebrated siege of La Rochelle. Montmorency continued to oppose the duke of Rohan, who remained in arms for 8 months after the taking of his party's stronghold, and thus contributed to bring about the peace of Alais (1629), which terminated the last of the religious civil wars in France. He moreover, in the same year, distinguished himself in Italy, and was at last appointed to a marshalship, which he considered but a meagre reward for his services. After his return to Languedoc he received overtures from Gaston of Orleans, the brother of Louis XIII., and was persuaded to join that prince in armed rebellion. He assembled his troops while Gaston was entering the kingdom from Lorraine at the head of a few thousand adventurers; but in the battle with the royalists at Castelnaudary in Sept. 1632, he was deserted by his ally, and taken prisoner. Arraigned before the parliament of Toulouse, he was sentenced to death, and by order of Richelieu publicly beheaded in the great square of that city, although all the

nobles prayed for his pardon. His life was written by Ducros, one of his officers (4to., 1688). III. MATHIEU JEAN FÉLICITÉ, vicomte and afterward duke of Montmorency, a French statesman, born in Paris, July 10, 1767, died March 24, 1826. He entered the army, served in the American war, was elected deputy to the constituent assembly in 1789, and was among the foremost, during the famous night of Aug. 4, to move for the spontaneous renunciation of all feudal privileges and titles of nobility. Alarmed, however, by the progress of the revolution, he emigrated in 1792. Returning after the fall of Robespierre, he kept aloof from politics, and lived on terms of intimate friendship with Mme. de Staël, and above all with Mme. Récamier, for the latter of whom his affection amounted almost to adoration. He received no favors from Napoleon, but on the return of the Bourbons he was appointed aide-de-camp to the count of Artois, peer of France, and in 1822 minister of foreign affairs. He was one of the French plenipotentiaries in the congress at Verona, the other being Châteaubriand; and on his return he became governor to the young duke of Bordeaux. Although he had no literary merit, he was elected to the French academy in 1825. He was noted for his piety, and breathed his last while at prayer in church.

MONTMORENCY, FRANÇOIS DE. See BOUTEVILLE.

MONTOUR, a central co. of Penn., intersected by the N. branch of the Susquehanna river, and drained by Chillisquaque, Mahanouring, and Big Roaring creeks; area, 210 sq. m.; pop. in 1850, 13,239. Its surface is hilly, being traversed E. and W. by several barren ridges, including Montour's and Limestone ridges and Muncy hills. There are several iron mines producing large quantities of metal. The valleys are fertile. The productions in 1850 were 126,217 bushels of wheat, 138,279 of Indian corn, 98,156 of oats, 14,899 lbs. of wool, 276,941 of butter, and 10,429 tons of hay. There were 11 grist mills, 4 saw mills, 3 foundries, 8 forges, 8 tanneries, 35 churches, and 8,715 pupils attending public schools. It is traversed by the North Branch canal, and by the Catawissa, Williamsport, and Erie railroad, passing through the capital, Danville.

MONTPELIER, a town in Washington co., Vt., and the capital of the state, situated on the Winooski river, 205 m. N. N. E. from Boston, in lat. 44° 17' N., long. 72° 36' W.; pop. in 1859, estimated at 8,000. The Winooski is here spanned by a substantial bridge, and its numerous tributaries afford water power. The village is built on low ground, and the streets are raised above the natural level. The state house was burned down in 1857, and has been replaced by a new edifice built upon the same plan somewhat enlarged. It is constructed of granite in the form of a cross; the entire length of the front is 176 feet, the depth of the main building 118 feet, and the height to the top of the dome 124 feet. It is surmounted by a

statue. There are 5 churches (Congregational, Episcopal, Free, Methodist, and Roman Catholic), 5 district schools, the Washington county grammar school, the Montpellier union district school, 2 insurance offices, 8 banks with an aggregate capital of \$250,000, 5 newspapers, an iron foundery, flour mills, and manufactories of sashes and blinds, carriages, timber, hats, caps, furniture, and plate, \$500,000 being invested in trade and manufactures of all sorts. Montpellier is a station of the Vermont central railroad. A history of Montpellier by D. P. Thompson was published in 1860 (Montpelier, 8vo.).

MONTPELLIER, a city of southern France, capital of the department of Hérault, situated on an eminence near the Lez, 80 m. S. W. from Nîmes, 17½ m. by railway N. W. from Cette, its port, and 76 m. W. N. W. from Marseilles; pop. in 1856, 40,577. It was once a place of some strength, but, except the citadel, there are now no considerable remains of its fortifications. The town gate on one side of the promenade du Peyrou was erected to commemorate in various bass-reliefs the glories of the reign of Louis XIV. The principal edifices are the modernized cathedral, the new *palais de justice*, the citadel, the anatomical theatre, and the *école de médecine*, an ancient and renowned institution, said to have been founded by Arab physicians, containing valuable anatomical collections, the doctor's robe in which Rabelais was here installed, and a library of 85,000 volumes and 600 MSS. The Musée Fabre, named after a Montpellier artist of that name, contains a portrait of Lorenzo de' Medici, as well as another picture, attributed to Raphael; the "Infant Samuel at Prayer," by Sir Joshua Reynolds; and other interesting works of art. The promenade du Peyrou, one of the finest public walks in Europe, adorned with an equestrian statue of Louis XIV., occupies the summit of a hill at one extremity of the city. Here, in a hexagonal tower, called *château d'eau*, is the great reservoir which supplies all the local fountains with water, itself being fed by an aqueduct 5 miles in length, and resting on 58 large and 188 smaller arches, measuring nearly 8,000 feet. The most important manufactures are woollens, muslins, printed cottons, table linen, hosiery, hats, leather, paper, brandy, earthenware, and oil. Montpellier is particularly renowned for its manufacture of verdigris, its chemical works, and its distilleries of brandy from the wines of the district. The botanical garden of Montpellier is said to have been the first established in France, and contains the *galactodendron*, the South American cow or milk tree, mentioned by Humboldt. Mrs. Temple (Narcissa), the step-daughter of the poet Young, is believed to have been buried in this garden, burial having been denied to her in the cemetery; some, however, contend that she was buried at Lyons. Montpellier is renowned for the mildness and salubrity of its climate, and is much frequented by consumptive invalids; yet it is often visited by the cold blasts of the mistral

winds. Cambacérès the statesman, Daru the historian of Venice, and Chaptal the chemist were natives of this city.

MONTPENSIER, ANNE MARIE LOUISE D'ORLÉANS, duchess of, better known as Mademoiselle, a French princess, born in Paris in 1627, died in 1698. She was the daughter of Gaston, duke of Orleans, the brother of Louis XIII.; and being moreover one of the richest heiresses in the world, her whole youth was passed in negotiations of marriage, which were defeated, as she declared, by the intrigues of Cardinal Mazarin. It was proposed to unite her to her cousin Louis XIV., who was 11 years her junior, to Philip IV. of Spain, to the prince of Wales, afterward Charles II., to the emperor Ferdinand III., to his brother the archduke Leopold, to the duke of Savoy, and to the king of Portugal. During the wars of the Fronde she sided with the Frondeurs, and compensated by her boldness and capacity for the weakness and indecision of her father. When it was proposed to send an expedition to Orleans she volunteered to command it, forced her way into the city by one gate while the royalists were vainly seeking admission at another, and secured the adhesion of the authorities to the cause which she favored. Returning to Paris in time to assist Condé at the battle of the Porte St. Antoine, she caused the guns of the Bastille to be fired upon the royal troops, though she still did not despair of becoming the wife of the young king. "That gun," said Mazarin, "has killed her husband." Banished with her father after the reestablishment of Louis' authority in Paris, she employed her exile in the composition of her *Mémoires*, which were first printed at Amsterdam in 1746, and have since been edited by Cheruel (4 vols. 12mo., Paris, 1856). After being recalled and again disgraced, she finally returned to Paris in 1660, and lived in comparative retirement until 1669, when at the age of 42 she fell in love with Lauzun, a poor Gascon noble 6 years younger than herself. The king, yielding to her entreaties, gave his consent to the marriage, but was afterward induced to revoke it and to commit Lauzun to the Bastille, where he was confined for 10 years. It is said, however, that a secret marriage had already taken place. Mademoiselle finally obtained her release by giving up two of her largest estates to the duke of Maine, the king's natural son by Mme. de Montespan, but Lauzun proved brutal and ungrateful. She forbade him her presence and passed the rest of her life in devotional exercises, unnoticed and almost forgotten.

MONTPENSIER, ANTOINE MARIE PHILIPPE LOUIS D'ORLÉANS, duke of, a French prince, born in the chateau of Neuilly, July 31, 1834. He is the 8d son of Louis Philippe, and at an early age served in the French army, distinguishing himself in Algeria in 1844 and 1845, and was promoted to the rank of general in 1846. On Oct. 10, 1846, he married Maria Luisa Ferdinanda de Bourbon, a sister of the present queen of Spain—an alliance which had been greatly opposed by England, on account of Louis Phi-

lippe's supposed ambitious designs. After the revolution of 1848, the duke of Montpensier removed with the rest of his family to England, and has since chiefly resided in that country and in Spain. He has 5 children, the youngest born in 1859. He holds a superior rank in the Spanish army.

MONTREAL, a city of Canada East, and the largest in British North America, situated in lat. 45° 31' N., long. 73° 35' W., at the base of the Royal mountain from which it takes its name, 180 m. S. W. from Quebec, 600 m. from the gulf of St. Lawrence, and 420 m. N. from New York, upon the S. side of a large island at the confluence of the Ottawa and St. Lawrence rivers. This island, also named Montreal, is about 30 m. long, by 10 at its greatest breadth, and is at the head of ship navigation. The population of Montreal in 1851 was 57,715; in 1856, 75,000; in 1860 (estimated), 86,000. The city is divided into an upper and a lower town, the former of which has wide streets and large handsome buildings, whose glittering tin or sheet iron roofs present a pleasing appearance from a distance. The building material most in use is a grayish limestone. The lower town has a cramped and gloomy aspect; the streets are narrow and ill-paved, and the houses are generally in the French style with dark iron shutters. Some of the public edifices are fine specimens of architecture. Christ church (Episcopal) cathedral, recently completed, is cruciform in plan, the nave and aisles being 112 feet long and 70 feet wide, and the transept 100 feet long and 25 feet wide; the tower is 224 feet high; the material is rough Montreal stone with facings of Caen stone. The Roman Catholic parish church on the Place d'Armes, constructed in the Gothic style, is 255 feet long and 134 feet wide; it has 6 towers, of which 3 belonging to the principal front are each 220 feet high; the principal window is 64 feet high and 32 feet broad; and the church is capable of holding from 10,000 to 12,000 people. The whole number of churches in 1858 was 30 (2 Baptist, 4 Church of England, 2 Church of Scotland, 2 Congregational, 1 Free, 1 French Protestant, 1 Huntingdonian, 1 Methodist, 3 Presbyterian, 8 Roman Catholic, 1 Unitarian, and 3 Wesleyan). The principal benevolent institutions are the home and school of industry; the general hospital of the sisters of charity or gray nuns for foundlings, orphans, and infirm persons, with a branch establishment for females; the Hôtel Dieu, under the charge of the hospital sisters of St. Joseph, who also attend St. Patrick's hospital; the house of charity attached to the English cathedral; 2 lying-in asylums; the Montreal general hospital; a dispensary, and an eye and ear institution; Protestant and Catholic Magdalen asylums; a Protestant and 2 Catholic orphan asylums; and the Providence asylum. Among the establishments for education is the university of McGill college, attached to which is the largest school of medicine in British North America, a faculty of law, normal and model schools, and a high

school; a chair of English literature was founded by a donation of \$20,000 from Thomas Molson, and several other gentlemen contributed \$2,000 each. The collège de Ste. Marie is directed by the Jesuits, and Montreal college by the Sulpicians. The collège de Ste. Thérèse and college of the Assumption are also Roman Catholic institutions. The Thomas Molson and Lower Canada colleges are private establishments. The Sulpicians have charge of the ecclesiastical seminary of St. Sulpice, and of the *grand séminaire*, the latter having about 50 students. Among the schools are the national, British, and Canadian, beside many excellent private academies. In 1858 there were 7 daily, 3 tri-weekly, 1 semi-weekly, and 5 weekly newspapers, and 13 monthly and other periodicals.—The principal banks are the Montreal, established in 1818, capital \$6,000,000, with a savings bank attached; the city bank, \$1,200,000; *banque du peuple*, \$1,200,000; bank of British North America, \$5,000,000; Molson's bank, \$1,000,000. These banks have their head offices in Montreal. The commercial bank, Ontario bank, and numerous other banks have branch offices in the city. The city and district savings bank transacts a large business. The Montreal and city banks possess very handsome and costly buildings on Great St. James street. The custom house is an elegant and stately edifice by the river side. The duty collected during the first 8 months of 1860 was \$1,629,730; during the same period in 1859, \$1,611,926. The merchants' exchange on St. Sacrament street is in the modern Italian style of architecture, and contains a well supplied reading room, a meeting room, and offices. The old government house on Jacques Cartier square, where the French governors held their levees, is now used for the Jacques Cartier normal school. The court house, a handsome new building erected at a cost of nearly \$800,000, faces a spacious esplanade called the Champ de Mars. A crystal palace was erected for an exhibition of the products of the province, and was opened by the prince of Wales, Aug. 25, 1860. One of the finest of the public edifices is the Bonsecours market, a Doric edifice crowned by a dome, and containing in the upper stories a concert or ball room capable of seating 4,000 people, and a number of offices. At the head of Place Jacques Cartier there is a column to the memory of Lord Nelson. The Victoria bridge across the St. Lawrence at Montreal was begun July 20, 1854. Its length, including the abutments, from bank to bank, is 10,284 feet, or nearly 2 miles. The tube which forms the girder and roadway is 6,600 feet in length, 16 feet wide, and 22 feet high, except at the extremities, where the height is only 19 feet. There are 24 piers. There were employed in its construction 3,000,000 cubic feet of masonry, 10,000 tons of iron, 2,000,000 rivets, &c. The cost was about \$6,000,000. It was completed in the autumn of 1859, and formally inaugurated on Aug. 25, 1860, on the occasion of the visit

of the prince of Wales.—The city is well lighted with gas. The original Montreal gas works were begun in 1836, but it was not till Nov. 1837, that any gas was used in the city. The new city gas company was incorporated in 1847 with a capital of \$3,000,000. Water is obtained from the St. Lawrence about 1½ m. above the Lachine rapids, and is conducted 5 m. through an open canal to the outskirts of the city, where a reservoir 623 feet long and 173 feet broad, with a capacity of about 15,000,000 gallons, has been erected at an elevation of 200 feet above the harbor. The works were begun in June, 1853, and water was admitted in Sept. 1856. The total expenditure up to Oct. 31, 1856, was \$1,140,000. A by-law authorizing the construction of a horse railway in the public streets was passed Sept. 12, 1860. From Nov. 1, 1855, to Nov. 1, 1856, 543 houses were built; in the year ending Dec. 31, 1857, 876; in 1858, 282; and about 400 in 1859.—The city government is vested in a mayor, 9 aldermen, and 18 councillors. There is an assessment of 7½ cents in the dollar on all real property within the city. The revenue of the city from the assessments imposed on real estate was, for 1850, \$60,880; in 1855, \$106,960; in 1856, \$115,044. The aggregate value of the real estate in 1856 was \$25,565,888. The total revenue from all sources in 1856 was \$285,082. Montreal is the see of an Anglican archbishop, who is the metropolitan of Canada, and of a Roman Catholic bishop. It is the head-quarters of the British army in North America.—Montreal is very favorably situated for manufactures, having unlimited water power within the city or in the immediate vicinity. Materials from foreign countries can be brought here without transshipment, and iron ore exists in the neighborhood within easy distance for water carriage. The Lachine canal affords excellent mill sites, but its waters were suffered to run to waste until 1846, when the commissioners of public works offered to lease a number of lots on the canal and river bank inside the upper basin for manufacturing purposes. There are now on the spot several flour mills, spike and nail factories, founderies, &c., and others have been established in various places. The principal manufactures now are axes, saws, India rubber shoes, cotton bags, woollens, paper, cordage, type, joiners' finishings, chairs, and steam engines. The port of Montreal in 1830 was not very large, but always secure for shipping during the time that the navigation of the river was open. A few years subsequently we find the quays of Montreal described as being unsurpassed by any in America, built of solid limestone, and uniting with the locks and cut stone wharves of the Lachine canal. The harbor commissioners are still making improvements. They are at present constructing a new basin for ocean steamers at the foot of McGill street, which will be 730 feet long, and will accommodate 3 first class steamships; the cost will be about \$76,000. They are also about to commence the rebuilding of the island wharf,

late Market island, at a cost of \$34,000; the wharf is to be continued below the Victoria pier, for a further distance of 2,500 feet, at a cost of \$64,000. In 1820 the average passage of sailing vessels between Quebec and Montreal was 16½ days; in 1821, 14 days; in 1822, 15½ days. In 1824 a tug steamer was put upon the route; and the passage is now made, with the aid of tug steamers, in about 30 hours. The first movement toward the steam navigation of the St. Lawrence was made Oct. 31, 1809, when the Accommodation started on her first trip to Quebec. It was considered dangerous to continue the voyage during the night, and 3 days were consumed in the downward trip and 4 in the upward. A few years later, boats were run during the night with perfect safety, overcoming all the former difficulties of the navigation. Public attention having been drawn to the importance of securing for Canada a line of steamships, in 1853 the government made a contract with Messrs. McLean and co. for the establishment of a regular line of mail steamers. The first vessel which arrived in pursuance of the contract was the Genova, which reached Montreal May 16. In 1854 the vessels of these contractors made 6 trips. In 1856 the vessels of the Montreal ocean steamship company made 14 voyages from Liverpool to Montreal and back, transporting from Liverpool to Canada 2,680 passengers and about 10,500 tons of goods; from Canada to Liverpool 1,724 passengers, 186,900 bushels of wheat, 52,400 barrels of flour, and 5,500 barrels of ashes. The following tables show the commerce of Montreal for a series of years:

Years.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
1853.....	259	59,712	256	59,712
1854.....	275	72,805	271	72,805
1855.....	198	47,394	185	47,394

	Imports.	Exports.
1856.....	\$16,144,096	\$2,117,004
1857.....	16,843,593	2,144,744
1858.....	11,594,098	6,000,000
1859.....	15,690,340	6,600,000

Being at the head of marine navigation proper, the city is the port for the great chain of river, lake and canal navigation which extends westward to Fond du Lac and Chicago, a distance of about 1,400 miles, embracing the largest extent of inland water communication in the world. The Lachine canal, the first in the link, extends from Montreal to Lachine, cuts across the southern point of the island, and avoids the Lachine rapids. The Beauharnois canal extends from the village of Beauharnois to Hungry bay, and passes the rapids of the Cascades, Cedars, and Steau. The Cornwall canal, commencing at Cornwall and ending at Dickinson's Landing, passes the Long Sault rapid. Farrand's Port, Rapid Plat, Point Iroquois, and Galop Rapids canals are short and detached. The Welland connects Port Dalhousie on Lake Ontario with Port Colborne on Lake Erie. The grand trunk railway connects the city with Portland, Me., and

all the principal places of Canada; and the Montreal and Plattsburg, extending to Lake Champlain, gives it communication with New York.—The settlement of Montreal dates from 1535, when Jacques Cartier established himself at the small Indian village of Hochelaga, which was the germ of the present city. In 1644 the entire island became by royal grant the property of the Sulpicians at Paris, one of whom, the abbé Quelus, shortly after landing, established the seminary of St. Sulpice in Montreal. On Aug. 16, 1642, the spot destined for the city was consecrated, and named Ville Marie, a name which it retained for a long period. Passing over an interval of 100 years, we find from a plan bearing the date of 1758 that Montreal was then surrounded by walls, flanked by 11 redoubts which served instead of bastions. The ditch, which was dry, was about 8 feet deep, and of a proportionate breadth. On Sept. 8, 1760, the town was surrendered to the British. In Nov. 1775, it was captured by the Americans under Gen. Montgomery, and held till the following summer. In 1797 the town contained about 1,200 houses, of which 500 only were within the walls; the rest were in suburbs, which commenced from the N., E., and W. gates. The houses in the suburbs were built principally of wood, but those within the walls were all of stone. At different times Montreal has suffered materially by fire. On May 18, 1765, a fire broke out in the city, and in a few hours destroyed 108 houses, and reduced 215 families to the greatest distress. A considerable sum was raised in England and forwarded for their relief. It was computed that one fourth part of the city in size was consumed, and about one third part in value, the loss being estimated at \$464,000. The population of Montreal at this period was about 7,000. On April 11, 1768, another conflagration broke out, and raged with incredible fury till 5 o'clock the next morning, when it partially subsided. Ninety houses, two churches, and a large charity school were consumed. In July, 1852, a fire consumed a large portion of the city; three fourths of the houses in the St. Mary's ward were swept away. The appearance of the city, however, has been greatly improved in consequence of this fire. Before 1852 the whole of the Quebec suburb, with very few exceptions, was an irregular collection of wooden houses, often of only one story, and it is now nearly rebuilt with good brick dwellings, covered with metal or gravel.

MONTREVEL, MARQUIS OF. See BAUME.

MONTROSE, a municipal, parliamentary, and maritime burgh of Forfarshire, Scotland, at the mouth of the South Esk, 70 m. N. E. from Edinburgh; pop. in 1851, 15,238. In that year it contained 5 spinning mills, which consumed annually nearly 6,000 tons of flax, and employed over 2,000 persons. The number of hands engaged in the manufacture of linen averages 1,400. The other leading industrial establishments are starch factories, iron founderies, and ship yards. The harbor is one of the

best on the E. coast of Scotland. Montrose unites with Arbroath, Brechin, Forfar, and Bervie in returning one member to parliament. Joseph Hume, the political reformer, was born in this town, and a statue was erected here to his memory in 1859.

MONTROSE, JAMES GRAHAME, marquis of, a Scotch soldier, born at the family estate of Auld Montrose in the autumn of 1612, hanged at Edinburgh, May 21, 1651. At the age of 14, on the death of his father, he became 5th earl of Montrose. Educated at the university of St. Andrew's, he won reputation as a classical scholar and as a poet. On Nov. 10, 1629, he married Magdalene Carnegie, who died in 1638, leaving 8 sons. Montrose then went abroad, and travelled for some years. Being ill received by Charles I. when he visited the court, he joined the Covenanters, who were then opposing that monarch's attempt to fasten episcopacy upon Scotland. He signed the covenant in 1638, and became one of the most influential members of the party. Being sent on a mission to Aberdeen, to induce the citizens to join the national cause, he met with some success; and he did his party good service in the north of Scotland. When the temporary peace of 1639 was made, Charles I. saw much of Montrose, and sought to gain him; but on the renewal of war in 1640, the earl led the vanguard of the Scotch infantry, and was distinguished in the brief hostilities that took place. Soon, however, his opinions underwent a change, and he became a royalist, on the ground that the Covenanters contemplated extreme measures against the government; and he was imprisoned in Edinburgh castle. Charles I. visited Scotland in 1641, and Montrose communicated with him, and was concerned in the plot called "the incident," supposed to have had for its object the murder of Argyle and other nobles. Released in November of that year, Montrose remained for some time on his estates. He went to York to wait on the king, who had written to him, but could not obtain an audience. In 1643 he joined the queen, Henrietta Maria, in England, but could not induce her to authorize him to pursue energetic measures for the royal cause in Scotland, and he returned home. The Covenanters endeavored to win him back to their cause, without success; and in the summer of 1643 he again went to England, and served with the king's army. On Feb. 1, 1644, he was appointed the king's lieutenant-general in Scotland, and proceeded to that country. Reaching the highlands, and working on the hatred which many of the clans felt for the Campbells, he raised a force there, and was joined by some Irish infantry. He then commenced a series of operations, the success of which threw a brilliancy over the royal cause, though circumstances prevented them from becoming useful to the king. On Sept. 1, 1644, he defeated the covenanting army under Lord Elcho at Tippermuir, and took Perth. On the 12th he destroyed another army, headed by Lord Louis Gorgon, in the battle of Aberdeen,

and took that town. After a variety of military operations, he entered Argyle's country, which he ravaged, and defeated the Campbells at Inverlochy, Feb. 2, 1645. Receiving large accessions of force, he marched against Dundee, which he stormed, but was compelled to abandon it on the approach of the enemy. On May 8 he encountered Sir John Urrie at Auldearn, and won the most brilliant of his victories. The victory of Alford was won July 2, over Gen. Baillie; whom he again met and conquered at Kilsyth, Aug. 15. Could he have kept his army together he might have possessed himself of all Scotland; but the highlanders formed an unstable force, and Montrose found himself almost without men when he marched to the border. On the morning of Sept. 13 he was surprised at Philiphaugh by David Leslie, and his army routed. In July, 1646, he capitulated to Middleton, and in September he went to the continent. High offers were made to him by the French government, which he would not accept. Visiting Prague and Vienna, he was made an Austrian marshal, and authorized to raise regiments for Charles I. He was greatly affected by the execution of that monarch. Charles II. renewed his commission, and made him a knight of the garter. Having received some arms and subsidies from Denmark, Sweden, Holstein, and Hamburg, he landed in the Orkneys in March, 1650, and proceeded thence to Scotland at the head of an ill-organized force of 1,500, but was speedily defeated and made prisoner. His enemies disgraced their cause by the cruelty of their conduct. He was sent to Edinburgh, where all manner of indignities were heaped upon him, and he was made to die on the gallows; but he baffled the malice of his foes by his determined bearing. His head was placed on the Tolbooth, and his limbs were sent to various parts of Scotland. After the restoration, his remains were collected, and received a public funeral. He had been elevated to a marquise by Charles I.—See "Montrose and the Covenanters," by Mark Napier (2 vols. 8vo., London, 1838).

MONTSERRAT, or MONSERRAT, one of the smallest of the British West India islands, belonging to the Leeward group, about equidistant, or 80 m., from the islands of Nevis, Antigua, and Guadeloupe; lat. of the N. point, 16° 50' N., long. 62° 12' W.; length 10 or 12 m., breadth 7½ m.; area estimated at 48 sq. m.; pop. in 1851, 7,058, little more than 2 per cent. of whom were white. About ¾ of the island is mountainous and barren, but the remainder, at the base of the mountain slopes, is fruitful and well watered. The soil is of a light volcanic description, well suited for the production of sugar, cotton, coffee, Indian corn, and indigo, beside all the tropical fruits and vegetables. The principal crop is sugar, though at one time indigo was largely grown. The E. side of the island is mostly uncultivated, covered with high mountains producing cedar and other useful and valuable trees; on the W. the land slopes

toward the sea. The climate is healthy. In 1855 the value of the imports was about £8,000, and of the exports nearly £20,000. The trade is mainly with other British West India islands. The chief town is Plymouth, on the S. W. coast; it is small, but neat, and the houses are well built of fine gray stone. In 1854 there were 19 schools attended by 1,628 scholars, more than half of whom were females. The government of Montserrat is administered by a president, under the governor-in-chief of the Leeward group, and an executive council of 8 members appointed by the crown, who also form the legislative council. There is a representative assembly, consisting of 12 members. In 1855 the revenue amounted to £8,500, and the expenditures to £8,264. This island was discovered by Columbus in 1493, and named after the mountain near Barcelona. In 1682 a party of Irish Roman Catholics from a neighboring island settled on it; and after a French invasion in 1712 it was finally made over to Britain by the treaty of Breda in 1746. Representative government was first established on Montserrat in 1699.

MONTSERRAT, or MONSERRAT, a mountain of Spain, on the right bank of the river Llobregat, in the province and 28 m. N. W. from the city of Barcelona. It is about 24 m. in circumference, and is broken into a large number of isolated calcareous peaks, the highest of which is 3,808 feet above the level of the sea. This mountain is remarkable for its hermitages and formerly had a rich monastery of Benedictines.

MONTUOLA, JEAN ÉTIENNE, a French mathematician, born in Lyons, Sept. 5, 1725, died at Versailles, Dec. 18, 1799. After studying at the Jesuits' college of Lyons and the law school of Toulouse, he established himself in Paris, where he became acquainted with D'Alembert and connected with the *Gazette de France*, a journal then almost exclusively devoted to science and literature. Beside other works, he published anonymously in 1754 *Histoire des recherches sur la quadrature du cercle* (new ed., 1830), and in 1758, *Histoire des mathématiques* (3 vols.). He was appointed intendant-secretary at Grenoble, and in 1764 he accompanied the chevalier Turgot in his colonizing expedition to Cayenne. On returning to France, he became commissioner of the royal buildings, and afterward royal censor of mathematical books. The former of these offices he held for 25 years till the revolution deprived him of it, and reduced him to poverty. Before his death he was admitted as a member of the institute. In 1798 he published a revised and improved edition of the first part of his "History of Mathematics;" but he did not live to complete the second part, which was finished after his death under the supervision of Lalande (2 vols. 4to., 1802). The continuation by Lalande is considered inferior to the earlier volumes.

MONZA (anc. *Medicia* or *Medetia*), a city of Lombardy, situated on the river Lambro, and forming almost a suburb of Milan, the distance from which city is 9 m. by railway; pop. about

8,000. It was the seat of government during the time of the Lombard kingdom, and many relics of that period are preserved in the cathedral, which was originally a basilica, founded by Theodolinda I. The most celebrated relic there is the iron crown, which Gregory the Great is said to have presented to Theodolinda, and which was used for the coronation of the Lombard kings and of the German emperors as kings of Italy, and more recently for that of Napoleon I. and the emperors of Austria. The sacristy of the cathedral is one of the most remarkable of mediæval museums. Among the public buildings of Monza beside the churches are the *broletto* or town hall, attributed to Frederic Barbarossa, two hospitals, a religious seminary, and various schools, &c. The palace of Monza, which was formerly the country residence of the Austrian viceroys, is surrounded by one of the most celebrated parks of Italy.

MOOLTAN, a city of India, in the Punjanb, situated 8 m. from the left bank of the Chenab, in lat. $30^{\circ} 8' N.$, long. $71^{\circ} 28' E.$; pop. about 81,000. It is built over the ruins of several more ancient cities, and formerly had a citadel crowning a high hill. This fortress was swept away by an inundation of the Chenab in 1849. The city is surrounded by a strong wall with 6 gates, outside of which lie extensive suburbs. The bazaars are large and richly stocked; an important banking business is carried on, and there are manufactures of silks, cottons, shawls, brocades, and tissues. Among the remains of ancient edifices scattered over the surrounding country is the magnificent shrine of the martyr Sham Tabresi.—Mooltan has been supposed to be the capital of the Malli which was taken by Alexander. It was captured by Tamerlane in the 14th century, and by Runjeet Sing in 1818, on which latter occasion nearly 3,000 of its defenders were massacred, and booty was carried off to the value of £4,000,000. In 1848 it was the scene of the massacre of two British officers by the Sikhs (see EDWARDS, LIEUT. COL. H. B.); and in Jan. 1849, it was captured by the British under Gen. Whish.

MOON, the satellite of the earth, the nearest of the heavenly bodies to us, is an opaque spheroid 2,160 m. in diameter, shining by reflecting the light of the sun. Situated at an average distance of 238,650 m., she revolves about the earth in 27 days, 7 hours, and 44 minutes. To this motion are due her monthly phases. The course of these, however, is only completed in 29 days, 12 hours, and 14 minutes, owing to the fact that they depend on her position relative to the sun, which is constantly advancing in the direction of her motion; so that, after completing 360° of her orbit, she has the whole amount of the sun's monthly progress, which is an arc of some 80° , to pass over before she can complete her course of phases. The former period is called the sidereal month, the latter the common or synodic month. When not eclipsed, she always presents to the sun an illuminated hemisphere; her phases depend on

how much of that hemisphere we see. If the earth be situated directly between her and the sun, we see all of it; if she is between us and the sun, we see none of it; if she is midway between these positions, we see half of it. In the first position, she is said to be in opposition; in the second, in conjunction; in the third, in quadrature, or quarter; and her phases, in order, are known familiarly as new, crescent, half-moon, gibbous, and full.—From the constancy of the physical features of the moon's disk, it is evident that she always presents to us the same hemisphere. To do this she must turn upon her axis precisely once while making one revolution in her orbit. There are indications that this is the general law of satellites. But it is not quite accurate to say that the moon constantly presents the same hemisphere to every observer upon the earth. Her axis of rotation being inclined one degree and a half to her orbit, and maintaining the same general direction in space as she moves round the earth, she appears to nod backward and forward in an arc of 8° in the course of every revolution, exposing to view the regions just beyond her N. and S. poles alternately. Nor is this all. As the moon's orbit, like that of every other planetary body, is an ellipse, her orbital velocity is not uniform, being most rapid when nearest the earth. Thus she sometimes gets ahead of her mean place, and sometimes lags behind it; and as her axial rotation is absolutely uniform, we are enabled to look over her edge, so to speak, now on the eastern and now on the western side. And again, the constancy of the direction of her hither hemisphere is to be referred to the earth's centre, so that the observer, situated upon the extremity of the earth's radius, views her from an elevation of nearly 4,000 miles; and when she is in the horizon it is plain he can look over her elevated edge, as it were. These several exposures are called the moon's librations: the first her libration in latitude; the second her libration in longitude; the third her diurnal libration.—To the casual observer the places of the moon in different seasons of the year seem exceedingly irregular, being sometimes seen, at the full, coursing along a circle which passes near the zenith in these latitudes, and sometimes, in the same phase, along an arc low down in the southern sky. It is plain that this is mainly owing to the inclination of the earth's equator to the ecliptic; but there is a large residual effect which is due to the inclination of the moon's orbit to the plane of the ecliptic, amounting to $5^{\circ} 8' 48''$, so that during one half of her orbit she is south of the sun's annual path, and during the remaining half north of it. The points where she crosses the ecliptic are known as her nodes; that at which she passes from the southern to the northern side of the line is called her ascending node, the other her descending node. If the ecliptic were a line of light ever conspicuous in the sky, and the moon's path intersecting it also a conspicuous line of light, the place of crossing would be seen to be

different every month, being removed further and further to the westward at intervals of about three diameters of the moon; so that the moon's path, month with month, would be represented by a series of nearly parallel lines about one and a half degrees apart. This movement is known as the retrograde motion of the nodes; the period of completing the whole circuit of the ecliptic is 18 years, 219 days. The orbit of the moon being an ellipse, having the earth at one of its foci, her distance varies in different parts of her monthly course. The nearest point of her orbit is called perigee, the furthest apogee; the two are known as apsides. These points are not fixed in position, but move forward from west to east, occupying successively every position in the circumference of the ellipse in the course of 8.85 years. These two remarkable motions, viz., of the nodes and of the apsides, are due to the disturbing action of the sun.—The question of the moon's habitability is of profoundest interest. We find upon her surface no indications of water, nor of an enveloping atmosphere. The absence of these fluids is explained by well known physical principles. It has been shown that her centre of figure does not coincide with her centre of gravity; that is to say, that one hemisphere is heavier than the other, the lighter half being turned toward the earth. These centres are found to be 83 m. apart. As an effect of this the atmosphere, unless its amount be very great, must collect on the further side, and all waters on the hither side be immediately evaporated and pass over also, on the mechanical principle that ponderable particles, if absolutely free to move, must arrange themselves uniformly around their centre of attraction, which is the centre of gravity of the resulting mass. Notwithstanding these evidences of the absence of two conditions essential for the sustenance of terrestrial life, a recent observer claims to have discovered indications of vegetation on the surface of the moon. These consist of certain traces of a greenish tint which collect and reappear periodically; much as the white spots covering the polar regions of Mars—supposed to be snow and ice—are observed to collect in the winter and waste in the summer of those regions of the planet. As we are able, under the most favorable conditions, to use upon the moon telescopic powers which have the effect to bring the satellite to within 120 to 150 m. of us, we should doubtless notice any such marked changes on her surface as the passage of the seasons produces, for example, on our own globe. In the most powerful instrument yet constructed, Lord Rosse's telescope, the surface of the moon presents a scene of wildest desolation. In every direction are circular caverns or pits, many of enormous size; the floor of one is seen to be strewn with huge blocks. The inner walls are commonly steep, and their depth often frightful, being many thousand feet. They are surrounded by annular ridges, the masses of which would ex-

actly fill the enclosed cavities. In the centre commonly rises a conical mountain. All this plainly points to a volcanic origin. There are large regions perfectly level, which Sir John Herschel thinks are of a decided alluvial character. There are great rings of mountains enclosing areas of 40 to 120 m. in diameter. From these ranges shoot up stupendous peaks, one to the height of 16,000 feet. Isolated peaks here and there rise abruptly from extended plains to the height of 6,000 to 7,000 feet. These elevations are determined by calculations based on the height of the sun above the horizon of the lunar place under inspection, and the length of the shadows cast. The most favorable time for observing these remarkable features is when the moon is crescent. Beyond the illuminated hemisphere mountain peaks, lifting themselves miles above the average level of the surface, will be bathed in sunlight, while the intermediate space is veiled in darkness, and will appear as silver points detached from the bright crescent; or, if a chain stretching toward the rising sun, they may appear as ragged promontories of light jutting far out into the darkness. An admirable chart of the moon has been constructed by the eminent Prussian observer, Beer and Mädler, whose work, *Der Mond*, must be consulted for a full account of the physical condition of our satellite. They place the height of one mountain at 22,823 feet. This, considering the relative magnitudes of the moon and the earth, is far more stupendous than any known elevation of terrestrial surface. More recently M. Secchi, astronomer at Rome, has succeeded in getting a photographic view of the crater called Copernicus, taken from a map executed with great care.—The mass of the moon is not accurately known, though the most trustworthy determinations agree in placing it at about $\frac{1}{80}$ part of the mass of the earth.—The faint apparition of the entire lunar disk at the time of new moon is considered to be due to the reflection of the light received from the earth, whose illuminated hemisphere is then turned toward her. It is disputed that the moon shines by reflected and not native light. Licetus, professor of philosophy at Bologna, suggested the idea that she possesses a phosphorescent quality, by virtue of which her light is simply the result of a propulsion effected by the sun's influence. This idea has been adopted by Professor Leslie; see his "Experimental Inquiry into the Nature and Propulsion of Heat" (London, 1804).

MOONDA, a river of western Africa, rises in the Sierra del Crystal and falling into Cameroo bay in the gulf of Guinea, 89 m. S. of the equator, in long. $9^{\circ} 31'$ E., after a W. course of a great length which has been but imperfectly described. Around its mouth there are some high hills, but further inland its banks are low mangrove swamps which exhale a deadly malaria. Bar wood, used as a dye by both the natives and Europeans, grows near it, and cameroo may be obtained in its forests. The river

villages bordering upon it are built on the dry ground back of the swamps. Mr. Du Chaillu, who ascended the Moonda for 60 m. in 1856 describes it as a very desolate river.

MOOR FOWL. See **PTARMIGAN**.

MOORCROFT, WILLIAM, an English traveller, born in Lancashire about 1780, died in 1825. He was educated for a surgeon, but devoted himself to veterinary practice in London. In 1808 he went to India as superintendent of the company's stud in Bengal. With the view of introducing stallions from the neighborhood of Balkh and Bokhara, and at the same time of establishing commercial intercourse with the trans-Himalayan districts, he undertook a journey in 1819, setting out from Bareilly in October, accompanied by Mr. George Trebeck, Mr. Guthrie, and two natives, to whom a party of Gorkhas were afterward added. All the expenses of the journey were defrayed from his private purse. After traversing the Himalaya by a route in which no European had preceded him, and determining the sources of the Chenab and the Hyphasis, he reached Ladakh in Sept. 1820, remained there two years, and then went to Serinagur, the capital of Cashmere, where he spent 10 months. Thence he travelled by way of the Pir Panjal mountains to the Punjab, visited Cabool and Bokhara, and was plundered of much of his property, but effected the purchase of a number of valuable horses, with which he set out on his return in the summer of 1825. At Andkho (lat. 37° 45' N., long. 66° E.) he died of fever, away from his party and under rather suspicious circumstances. His body was carried to Balkh, and there Mr. Guthrie also died. Mr. Trebeck expired shortly afterward at Mazar. Though there seems little room to doubt of the time and place of Moorcroft's death, Father Hue, who visited Lassa in 1846, was told by a servant of the English traveller, and by the regent and Cashmerian governor, that Moorcroft arrived at that city from Ladakh in 1826, lived there 12 years in the disguise of a Cashmerian, and was finally killed by robbers on his way back to Ladakh in 1838. It was only on the examination of his papers, among which were numerous maps, that his real name and character were discovered. An account of his explorations up to his arrival at Bokhara, compiled from the journals and other papers of the travellers, was published by Prof. H. H. Wilson (2 vols. 8vo., London, 1841).

MOORE, a central co. of N. C., drained by Deep, Little, and Lumber rivers; area, about 700 sq. m.; pop. in 1850, 9,482, of whom 1,976 were slaves. It has a diversified surface, and the soil is fertile near the streams. The productions in 1850 were 223,476 bushels of Indian corn, 27,828 of wheat, 555 bales of cotton, and 8,500 lbs. of tobacco. There were 8 grist mills and 2 saw mills, 24 churches, and 1,400 pupils attending public schools. Capital, Carthage.

MOORE, BENJAMIN, D.D., an American clergyman, bishop of the Protestant Episcopal church in the state of New York, born in New-

town, L. I., Oct. 5, 1748, died in New York, Feb. 27, 1816. He was graduated at King's (now Columbia) college in 1768, commenced at once the study of theology, and at the same time gave private instruction in Greek and Latin to a number of pupils. In May, 1774, he went to England to obtain orders, and in June of the same year was ordained deacon and priest by Dr. Terrich, bishop of London. On his return to New York, he became an assistant minister of Trinity church, and succeeded to the rectorship, Dec. 22, 1800. Bishop Provost of New York having resigned his episcopal jurisdiction in Sept. 1801, Dr. Moore was unanimously elected his successor, and was consecrated at Trenton, N. J., Sept. 11, 1801, during the session of the general convention. He was also rector of Trinity church and president of Columbia college. In Feb. 1811, he was attacked by paralysis, which rendered him incapable of further active duty, and Dr. Hobart became assistant bishop in May of the same year. A collection of Bishop Moore's sermons (2 vols. 8vo., New York) was published after his death by his son Clement O. Moore.

—**CLEMENT O., LL.D.**, an American scholar, son of the preceding, born in New York, July 15, 1779. He was graduated at Columbia college in 1798, and, having applied himself to the study of Hebrew, published in 1809 in 2 vols. a Hebrew and English lexicon, with notes, a grammar, and a complete vocabulary of the Psalms. When a diocesan seminary was established in New York, after the removal of the general theological seminary to New Haven, Mr. Moore was appointed professor of "biblical learning, the department of interpretation of Scripture being added;" and on the union of the two institutions in Dec. 1821, under the name of the general Protestant Episcopal seminary, he was reappointed with the title of professor of Hebrew and Greek literature, which was afterward changed to oriental and Greek literature. To this institution he afterward made a gift from his family inheritance of the large plot of ground where it stands in the city of New York. He retired with the title of emeritus professor in June, 1850. Mr. Moore has published a collection of "Poems" (12mo., New York, 1844), and "George Castriot, surnamed Scanderbeg, King of Albania" (12mo., 1850).

MOORE, EDWARD, an English poet and essayist, born in Abingdon, Berkshire, in 1712, died in London in Feb. 1757. For some time he followed the business of a linen draper in London. His first poetical work, entitled "Fables for the Female Sex," appeared in 1744. "The Trial of Selim" was a complimentary offering to one of his patrons, Lord Lyttelton. He next produced two comedies: "The Foundling," first acted in 1748, and "Gil Blas," in 1751, both of which failed. His tragedy of "The Gamester," however (1753), in the composition of which he is said to have received material assistance from Garrick, achieved a popularity and is still performed. His last

literary undertaking was the editorship of "The World," a weekly miscellany.

MOORE, JACOB BAILEY, an American journalist and author, born in Andover, N. H., Oct. 31, 1797, died Sept. 1, 1853. He was at first an apprentice and afterward partner and brother-in-law of Isaac Hill, the printer of the "New Hampshire Patriot," at Concord, and after the dissolution of their partnership in 1823 became a bookseller and publisher. One of his principal publications was a series of "Collections, Topographical, Historical, and Biographical, relating principally to New Hampshire," begun in 1822 and finished in 1824, which he edited with the assistance of Dr. John Farmer. In 1826 he commenced the "New Hampshire Journal," a whig newspaper, which he conducted until 1829; it was subsequently united with the "New Hampshire Statesman." He was a member of the state legislature in 1828, sheriff of Merrimack county from 1829 to 1834, connected for a short time with the "Concord Statesman," and in 1839 editor of the New York "Daily Whig." Under President Harrison he was appointed to a clerkship in the post office department at Washington. Removed by President Polk, he returned to New York, and accepted the post of librarian of the historical society. During the administrations of Taylor and Fillmore he was postmaster at San Francisco. Mr. Moore left several historical and other works, the principal of which are: "A Gazetteer of the State of New Hampshire," compiled with the assistance of Dr. John Farmer; "Annals of the Town of Concord, to which is added a Memoir of the Penacook Indians" (1824); "Laws of Trade in the United States" (1840); and "Memoirs of American Governors" (1846). The last work was the first volume of a series never completed, which was designed to embrace all the colonial and provincial governors to the revolution.—Of his sons, GEORGE H., now librarian of the New York historical society, is the author of a volume on "The Treason of Major-General Charles Lee" (New York, 1860); and FRANK has published "Songs and Ballads of the American Revolution" (12mo., New York), "American Eloquence" (2 vols. 8vo., 1857), and "Diary of the American Revolution" (2 vols. 8vo., 1860).

MOORE, JOHN, a Scottish physician and author, born in Stirling in 1729, died at Richmond, near London, in 1802. He was graduated at the university of Glasgow, and travelled extensively on the continent of Europe, principally as a private tutor, and afterward practised medicine in London. He wrote "A View of Society and Manners in France, Switzerland, and Germany" (1779), and "A View of Society and Manners in Italy" (1781); "Zeluco," the most popular of his novels (London, 1789); and various other works. A uniform edition of his writings, with a memoir of his life, was prepared by Dr. Robert Anderson (7 vols. 8vo., Edinburgh, 1820).

MOORE, SIR JOHN, a British general, eldest son of the preceding, born in Glasgow, Nov. 18,

1761, fell in battle at Corunna, Jan. 16, 1809. He was educated chiefly on the continent while his father was travelling with the duke of Hamilton. The interest of the duke procured him a commission in the army in 1776, and he served in Minorca and afterward in America until 1778 when his regiment was disbanded. Through the influence of his former patron he obtained a seat in parliament, which he held for a short time. In 1787 he was promoted to the rank of major, and in 1790 he became lieutenant-colonel of his regiment, which he accompanied the next year to Gibraltar. The year following he was sent to Corsica, where he particularly distinguished himself under circumstances of great difficulty, and received his first wound while storming the Mozello fort. Upon his return to England in 1795 he was made general of brigade, and attached to a division of foreign troops proceeding to the West Indies. He took part in the capture of St. Lucia, and Sir Ralph Abercromby appointed him governor of the island. In this situation he displayed great sagacity and moderation, and completely subdued the bands of insurgent negroes that infested the island; but the state of his health obliged him to return to his native country in August, 1797. Sir Ralph Abercromby having received command of the forces in Ireland he requested that Gen. Moore should be placed on his staff, and during the rebellion of 1798 the latter rendered important services for which he was raised to the rank of major-general. Speaking of this insurrection in his journal, Moore says that "the people would certainly be quiet if the gentlemen and yeomen would only behave with tolerable decency, and not seek to gratify their ill humor and revenge upon the poor." In June, 1799, he accompanied the duke of York on his disastrous expedition to Holland, was severely wounded in 3 places, and returned to England, where he arrived in the latter part of August. In 1800 a force was sent up the Mediterranean, under Sir Ralph Abercromby, who named Moore as one of the major-generals; but it was not until the following year, when the troops proceeded to Egypt that he had an opportunity of distinguishing himself. In the landing at Aboakir, March 2, 1801, and the engagements with the French troops upon that day, the 13th, and the 21st Moore was actively employed, and received a sabre wound in the chest and a bullet in the thigh. On the surrender of Alexandria he returned to England, and was made a knight of the bath. He was now engaged for some time in a camp of instruction in Kent, where he displayed as much talent for training men as he had formerly done for leading them. He afterward went to Sicily, and thence, in May, 1805, at the head of 10,000 men, to Sweden to assist in the defence of that country against Napoleon; when, had it not been for the ability and resolution of Moore, all his men must have been sacrificed. He returned with his troops to England, and was immediately sent to Portugal.

where, after the expulsion of the French from that kingdom, and the recall of the British general who had negotiated the convention of Cintra, Sir John was appointed to the command of the army intended to coöperate with the Spanish forces in the Peninsula against the French. He was assured that upon entering Spain he would be joined by 60,000 or 70,000 men, and began his advance from Lisbon in October, 1808, but soon discovered that the patriotic enthusiasm which had been expected did not exist, and that the defeat of the Spanish forces at all points left little hope of a successful campaign. On Nov. 13 Moore found himself at Salamanca with an advance corps, within 3 marches of the French army, and without any Spanish assistance. He had only 3 brigades of infantry and not a single gun in Salamanca; and though the remainder of his forces were on the road to join him, they could not arrive for several days. Notwithstanding his critical position, he determined to risk an advance with a view of drawing the mass of the French force toward the N. of Spain, and thus afford the Spanish armies time to rally. But there was now no army left in the field to oppose the French except his own, and Napoleon at the head of a large force, together with the whole of the French armies in the Peninsula, was advancing to surround him, and it was evident that Moore with 23,000 men could not maintain his position. It was the depth of winter, and his retreat, which began Dec. 11, had to be effected through a mountainous and dreary region in the face of a force vastly superior to his in numbers. The British rear guard quitted Astorga Dec. 31, and having 3 times checked their pursuers, joined the main army at Lugo, where for two successive days battle was offered to Soult by Moore, but not accepted. The retreat commenced afresh, and they reached Corunna Jan. 11, 1809, and 5 days afterward fought and won the battle in which their commander fell by a cannon shot. The troops made good their escape to their ships. Moore was interred in the citadel of Corunna, which surrendered to the French a few days after the departure of the British. Soult caused a monument to be erected to his memory, which is also preserved in the well known lines written upon his burial by Charles Wolfe. Soult, Wellington, and Napoleon have alike borne tribute to the ability of Sir John Moore, whose talents and firmness alone saved the army under his command from destruction. The British parliament had a monument erected to him in St. Paul's cathedral; and his native city raised a bronze statue to his memory at the cost of £3,000.

MOORE, MATRICK, an American patriot and jurist, born in Brunswick co., N. C., died in 1777. He belonged to an Irish family of which the present head is the marquis of Drogheda, and was a grandson of Sir Nathaniel Moore, governor of Carolina in 1705. Having studied for the bar, he acquired a high reputation as a lawyer, was one of the 3 colonial judges of North

Carolina at the time of the revolution, was a member of the provincial congresses which met at Hillsborough in 1775 and at Halifax in 1776, and had a prominent part in framing the constitution of North Carolina. He was one of a committee appointed at the commencement of the revolution to draw up an address to the people of Great Britain on the wrongs of the North American colonies.—ALFRED, son of the preceding, born in Brunswick co., N. C., May 21, 1755, died Oct. 15, 1810. At the age of 20 he became captain in a regiment of North Carolina troops commanded by his uncle Col. James Moore, but was soon afterward obliged to resign in order to provide for his destitute relatives. When the British seized Wilmington, however, he raised a troop of volunteers, with whom he rendered great service to the American cause. In order to alleviate the distress to which his patriotism had reduced him, the general assembly in 1790 made him attorney-general; and though he had not yet mastered the first rudiments of law, he soon attained, by hard study, a foremost rank in his profession, was raised to the bench in 1798, and became associate justice of the supreme court of the United States in 1799. He resigned on account of bad health in 1805.

MOORE, NATHANIEL F., LL.D., an American scholar, born in Newtown, L. I., Dec. 25, 1782. He is a nephew of Bishop Benjamin Moore, was graduated at Columbia college, New York, in 1802, and was admitted to the bar in 1805. He was appointed in 1817 adjunct professor and in 1820 professor of the Greek and Latin languages in Columbia college, retaining this chair until 1835, when he resigned and visited Europe. He had collected a valuable library, which the college purchased in 1837, and at the same time appointed him librarian. In 1839 he made a second voyage to Europe, and extended his travels as far as Egypt and the Holy Land. In 1842 he succeeded Judge Duer in the presidency of Columbia college, from which he retired to private life in 1849. Beside a number of pamphlets and essays, Mr. Moore has published "Ancient Mineralogy" (1 vol. 12mo., New York, 1834; new ed., 1859); "Remarks on the Pronunciation of the Greek Language," in reply to a pamphlet by Mr. Pickering; "Lectures on the Greek Language and Literature;" and a "Historical Sketch of Columbia College."

MOORE, RICHARD CHANNING, D.D., an American clergyman, bishop of the Protestant Episcopal church in Virginia, born in New York, Aug. 21, 1762, died in Lynchburg, Va., Nov. 11, 1841. He was educated in King's (now Columbia) college, New York, and for a brief period followed a seafaring life, after which he studied medicine. Dissatisfied with this calling, he turned his attention to the ministry, and in July, 1787, was ordained a deacon of the Protestant Episcopal church by Bishop Provost of New York, being the first Episcopal minister who received orders in that state.

Soon after he took charge of a small parish in Rye, Westchester co. In the latter part of 1789 he was called to a much larger parish, embracing the whole of Staten island, with which he remained connected 20 years. In 1809 he accepted an invitation to the rectorship of St. Stephen's church in New York, and in 1814 he was elected to succeed Bishop Madison as bishop of Virginia. Removing thither soon after his consecration, he was appointed rector of the Monumental church in Richmond, a position which he occupied until the close of his life. The efforts of the new bishop were unremittingly exerted to build up the nearly exhausted diocese committed to his care; and so well directed were his labors and so beneficial his example and influence, that at the time of his death the number of Episcopal clergymen in Virginia had increased to upward of 100. During the last 12 years of his life his episcopal duties were shared by Bishop Meade, who had been appointed his assistant, and who succeeded him in office. He was a prominent leader of the evangelical branch of the church.

MOORE, THOMAS, an Irish poet, born in Dublin, May 28, 1779, died at Sloperton cottage, Devizes, Wiltshire, Feb. 26, 1852. By his father, John Moore, a dealer in groceries and spirits, he was brought up in the Roman Catholic faith; and at the school of Mr. Samuel Whyte, a former teacher of Sheridan, he acquired a taste for music, recitation, and dramatic performances, having as early as his 10th year been one of the "show scholars" in the plays gotten up by his fellow pupils. Of his early attempts at verse making he says: "So far back in childhood lies the epoch, that I am really unable to say at what age I first began to act, sing, and rhyme." In 1793 he became a contributor to the "Anthologia Hibernica," a Dublin magazine, subsequently the receptacle of a number of his juvenile poems, which he characterized generally as "mere mock-birds' song;" and in 1794 he was entered a student of Trinity college, Dublin. The period was one of great political excitement in Ireland, but the watchful care of his mother preserved him from any active participation in the plots against the government, in which many of his fellow students were involved. Having taken his degree of B.A., he repaired in 1799 to London to pursue the study of the law in the Middle Temple, carrying with him also a translation of the odes of Anacreon commenced in his school days, and which he proposed to publish by subscription. To the law he gave little attention, but his subscription proved successful; and gaining the acquaintance of the earl of Moira, Lady Donegal, and other influential persons, he was introduced to some of the fashionable circles of the metropolis, where his genial manners and literary and musical accomplishments soon made him a favorite. His "Anacreon," which appeared in 1800, dedicated to the prince of Wales, to whom he had been presented by Lord Moira, was favorably received; and a year

later he produced a volume of original poems under the title of "The Poetical Works of the late Thomas Little, Esq.," a pseudonyme suggested by his diminutive stature. With much that was polished, tender, and natural, the volume contained many pieces of very questionable morality, which were excluded from the collected editions of his poems. In 1803, through the influence of the earl of Moira, he was appointed registrar to the admiralty in Bermuda, where he arrived in Jan. 1804. A few months sufficed to show him that the office was neither lucrative nor adapted to his tastes; and intrusting his business to a deputy, he returned to England, having first made a rapid tour over a portion of the United States and Canada. This part of his life, more than any other, is interwoven with his poetry; and in his "Odes and Epistles," published in 1806 and dedicated to the earl of Moira, he has presented a series of poetical notes of his progress from place to place, which are among the most successful of his minor productions. He commented with severity upon American institutions and the poverty of western literature, but subsequently confessed that his views were mere boyish impressions. In some of these poems the pruriency bordering on libertinism which had characterized "Little's poems" was again discernible, and the volume was severely handled by Jeffrey in an article in the "Edinburgh Review," in which Moore was called "the most licentious of modern versifiers, and the most poetical of the propagators of immorality." The latter immediately sent the reviewer a challenge, and a hostile meeting took place at Chalk Farm, Aug. 12, 1806, which was interrupted by the police before either party had fired a shot. The subsequent discovery that one of the pistols had no bullet gave rise to a story that Moore and Jeffrey had fought with unloaded pistols, and Byron, in his "British Bards and Scotch Reviewers," made a ludicrous allusion to "Little's leadless pistols," for which he was called to account by Moore. A second duel was however avoided, and thenceforth Moore was on terms of warm friendship with both of his antagonists. For several years he led a life of fashionable excitement, a frequent visitor at the seats of his patron, Lord Moira, Lords Lansdowne, Holland and other whig peers, through whose influence he looked for some preferment (which however never came), but making no serious attempt to support himself by his pen. In 1811, however, upon being married to Miss Bessy Dyke, an estimable young actress, literature became necessary as a profession. Having tried his hand at serious satire in his "Corruption," "Intemperance," and the "Sceptic" (1808-'9), he in a happy hour attempted *jeux d'esprit* and political squibs, conceived in a lighter vein, and their very lightness more sure to hit the mark. A felicitous example of this species of composition was the "Twopenny Post-Bag" (1811), written like most of his similar pieces in the interest of the whig party, and which, as a

compound of causticity and point with sprightly humor and witty illustration, is in its way unexcelled. These productions continued for many years to be a source of profit to him. For the severity with which he handled the prince regent in some of them Moore has been accused of ingratitude; but, according to his own account, the attentions which he received from the prince were limited to two invitations to dine at Carlton house, and one to attend a grand fête in 1811. In July, 1813, he was established at Mayfield cottage, near Ashbourne in Derbyshire, a place connected with some of his most important literary labors, and which continued for several years his home. Here were written many of the songs adapted to the ancient music of his native country, which, under the name of "Irish Melodies," will ever be identified with his genius and patriotism. They had been commenced as early as 1806, at the suggestion of Mr. Power, a music publisher, and ultimately were extended to 10 series. For the arrangement of the melodies he was indebted to the composer, Sir John Stevenson. On these songs, which have enjoyed a popularity beyond that of any similar poems in the English language, his fame with posterity may be safely permitted to rest; and without adopting the eulogistic language of Byron, that certain of them are "worth all the epics that ever were composed," it is hazarding little to predict that many of them will survive his longer and more ambitious strains. To the lyric department of his poetry were subsequently added 4 series of "National Airs," 2 of "Sacred Melodies," "Legendary Ballads," and many miscellaneous pieces, the airs and arrangements for which were prepared by Sir John Stevenson or himself. In the latter part of 1814 Moore agreed to furnish the Messrs. Longman with a poem of the same length as Scott's "Rokeby," for which he was paid £3,000. The idea of writing an oriental romance had occurred to him several years previous, and at the time of making the contract much of the preliminary reading and a portion of the poem were completed. Two more years of labor produced his "Lalla Rookh," a series of 4 eastern stories, connected by a thread of prose romance. It is the most labored of his works, rich and melodious in the composition, and glowing with a wealth of imagery which wearies by its very excess. So true nevertheless were its pictures of eastern life, that Col. Wilks, the historian of British India, could not believe that Moore had never travelled in the East; and the compliment which Luttrell paid him, when he told him that his

. lays are sung

By moonlight in the Persian tongue
Along the streets of Ispahan,

is literally true, the work having been translated into Persian, and read with avidity among many oriental nations. Flushed with the success of "Lalla Rookh," which has since gone through more than 30 editions, the poet accompanied Rogers on a pleasure trip to Paris, where

he obtained the materials for his "Fudge Family in Paris," published in 1818, and succeeded in 1819 by "Tom Crib's Memorial to Congress," both choice specimens of his satiric muse. About this time, at the request of the marquis of Lansdowne, he took up his residence at Sloperon cottage, near Bowood, the seat of that nobleman; but had scarcely got settled when intelligence reached him, that in consequence of the faithlessness of his agent in Bermuda, he was involved to the extent of £6,000. Many offers of assistance were made to him, which he steadily declined; and in Sept. 1819, he repaired to Paris to avoid an attachment issued by the court of admiralty for his arrest. Soon after he accompanied Lord John Russell on a journey to Italy, in the course of which he visited Byron at Venice. His impressions of travel were recorded in his "Rhymes on the Road" (1819), a series of poems of unequal merit, which he himself characterized as little better than "prose fringed with rhyme." Establishing himself in Paris in 1820, he sent for his family and resumed his literary pursuits. In Sept. 1822, he received intelligence that, after a tedious negotiation, the claim against him had been reduced to 1,000 guineas, toward the discharge of which the uncle of his agent had contributed £300, while the marquis of Lansdowne deposited a check for the balance; and he at once gladly returned to his Wiltshire cottage. In this year appeared his "Loves of the Angels," a poem founded on oriental legends, but much inferior to "Lalla Rookh." It was followed by "Fables for the Holy Alliance" (1823), one of his series of metrical satires; a witty party pamphlet entitled "Memoirs of Captain Rock" (1824); "Life of Sheridan" (1825), a work containing much information, though rather ornate in style; and the "Epicurean" (1829), an exquisite prose fiction. His most important prose work, however, was his "Notices of the Life of Lord Byron" (2 vols. 4to., 1830), founded on the journals and memorandum books of the poet, and an immense mass of correspondence furnished by Murray the publisher and others. Ten years previous Byron had intrusted to Moore an autobiography, more or less complete, extending to 1820, to be published after his death, and which the latter in 1821 disposed of to Murray for £2,000. The sudden death of Byron in 1824 revealed the existence and projected publication of this manuscript, and Moore was persuaded into an arrangement by which it was repurchased from Murray and burned, on the ground that it contained disclosures affecting the character of many persons, living and dead. Although absolved from any intention to do injustice to the memory of his friend, Moore has not escaped severe censure for destroying a manuscript which Byron had intrusted him with as a vindication of his name and honor, particularly as the objectionable passages, according to Lord John Russell, did not exceed 3 or 4 pages. With such materials as were subsequently procured

he compiled an excellent biography, for which he received from Murray the liberal sum of £4,870. His remaining works comprise "The Summer Fête" (1831), a poem; "Memoirs of Lord Edward Fitzgerald" (1831); "Travels of an Irish Gentleman in Search of a Religion" (1833); and the "History of Ireland" (4 vols. 12mo., 1835), written for Lardner's "Cabinet Cyclopædia." He wrote little else beyond an occasional trifle in verse for the periodicals, and the prefaces and a few additions to a collected edition of his poetical works, published by the Longmans in 1841-'2 in 10 vols. During his long residence at Sloperton cottage he was often absent in the gay circles of the metropolis, where his wit and genial humor ever made him a welcome guest; but his latter years were clouded by domestic grief, his children having all died before him, and by mental imbecility caused by a softening of the brain. "To the last day of his life," says Lord John Russell, "he would inquire with anxiety about the health of his friends, and would sing, or ask his wife to sing to him, the favorite airs of his past days. Even the day before his death he 'warbled,' as Mrs. Moore expressed it; and a fond love of music never left him but with life." In 1835 a literary pension of £300 was conferred on Moore, and in 1850 a pension of £100 was settled on his wife, "in consideration of the literary merits of her husband and the infirm state of his health." He had also by his own computation received for copyright not less, in the whole, than £20,000, and had at different periods of his life been in the receipt of £500 per annum from Power, the publisher of his "Melodica," and of a salary of £400 or £500 for political squibs contributed to the "Times." His yearly outgoings had exhausted these sums, and to provide for the necessities of his wife, his "Memoirs, Journal, and Correspondence" were sold for £3,000 to the Longmans, who published them in 8 vols. (1858-'6), under the editorial supervision of Lord John Russell, in accordance with the testamentary desire of the poet. The journal, embracing the period between 1818 and 1847, gives a tolerably good idea of his daily life; and in his letters the engaging traits of his character are abundantly displayed. Those addressed to his mother, to whom during the greater part of his life he wrote twice a week, are replete with expressions of tenderness, "flowing from a heart uncorrupted by fame, unspoilt by the world." Amid all the demands of the society which courted and flattered him, and in which he perhaps passed too much of his time, he preserved his domestic affections unchanged, and was a devoted son, husband, and parent. To his wife he paid "the homage of a lover," and was rewarded by an affectionate devotion which ended only with his life. Moore has sometimes been censured for his presumed partiality for fashionable life and the acquaintance of titled personages; but his vanity could as little resist the fascinations of public applause, as his buoyant spirits could endure total

seclusion from the world in his rural home, to which, however, he never returned without genuine emotions of delight. It must be added that throughout life he preserved his independence of character, and that with abundant self-esteem he was uniformly just and considerate to his literary contemporaries.

MOORE, ZEPHANIAH SWIFT, D.D., the first president of Amherst college, born in Palmer, Mass., Nov. 20, 1770, died June 30, 1823. He was graduated at Dartmouth college in 1793, entered the ministry, and preached at Leicester from 1798 until 1811, when he was appointed professor of languages in Dartmouth college. He was chosen president of Williams college in 1815, on the retirement of Dr. Fitch; but failing to procure the removal of the institution to the banks of the Connecticut, he resigned in 1821, and was chosen president of Amherst college.

MOORS (Lat. *Mauri*; Sp. *Moros*; Dutch *Moors*), the people of Mauritania or Morocco. The Arabs who conquered Mauritania in the 7th century converted to Mohammedanism the native population, who in Europe were called Moors, though in their own language they called themselves Berbers, while by the Arabs they were termed Moghribes, "westerners" or "men of the west." Arabic manners and customs, and in a corrupt form the Arabic language, soon prevailed in the country, the Arab conquerors freely amalgamating with their converts, who far exceeded them in numbers. In 711 an army drawn from this mixed population under Arab leaders, crossed the straits at Gibraltar, so named from their leader, and began the conquest of the Spanish peninsula. The Spaniards and Portuguese called these invaders Moors because they came from Mauritania, and the term Moors with them soon became synonymous with Mohammedans or Moslems, as the invaders designated themselves. The Spanish writers subsequently applied the term to all the Mohammedans of northern Africa; and when at the close of the 15th century, the Portuguese made their way around the cape of Good Hope and encountered the Arabs on the coasts of E. Africa and of S. Asia, they still called them Moors. Even the Turks, who in race, in language, and in every thing but religion, were foreign and alien to both Moors and Arabs, were sometimes loosely spoken of as Moors by the Spanish historians.

MOORUK, the native name of a species of cassowary, discovered in 1857 in the island of New Britain, and named by Mr. John Gould *casuaris Bennettii*, in honor of Dr. George Bennett of Sydney, N. S. W., who first brought it to the notice of the scientific world. The height of the bird when standing erect is 5 feet of which the neck is 2; the color rufous marked with black on the back, and raven black about the neck and breast; the loose wavy skin of the neck is iridescent with tints of bluish purple, pink, and green; the feet and legs are large and strong, pale ash-colored, the claw of the hind toe being nearly 8 times as long as the other.

there is a horny plate on the top of the head, resembling pearl colored with black lead; the bill is narrower, longer, and more curved than in the emu, somewhat like that of a rail, with a black leathery cere at the base, and a small tuft of black hair-like feathers behind the plate, continued here and there over the neck; the wings are rudimentary; for the generic characters, see CASSOWARY. Living specimens have been exhibited at the London zoological gardens. It seems to form the link between the emu and the cassowary, resembling the former in its bearing and gait; it also resembles the kiwi-kiwi (*apteryx*) in the style of its motions and attitudes; it is tame and familiar in captivity, and when pleased dances about its place of confinement; it will thrive on boiled potatoes, with occasionally a little meat; it emits a peculiar whistling chirping sound, and some louder notes resembling the name given it by the natives; it is shy, difficult to approach, and still more difficult to pursue on account of its speed in running through the thick brush and its extraordinary power of leaping; it has all the inquisitiveness of the domesticated fowls. The eggs are of about the same size and form as those of the common cassowary, having in most cases thick tuberculated shells; they vary from 13 to 14 inches in circumference in the longest diameter, and from 11 to 11½ in the widest; the color is pale olive green, with darker olive tubercles; sometimes they are smooth and without spots.—Another cassowary, not mentioned in its proper place, is the Australian species, *C. australis* (Wall), discovered in the Cape York district in 1854. It is about the same size as the mooruk; the head is without feathers, covered with a bluish skin, and has a protuberance or helmet of a bright red color; the skin of the neck has 6 or 8 round fleshy balls of blue and scarlet; the body is thickly covered with dark brown wiry feathers; the wings are mere rudiments. The flesh was eaten by its captors, and was said to be delicious. It is stronger and heavier than the emu, very wary, and not easily killed except by the rifle.

MOOSE WOOD. See MAPLE.

MOQUIS, or MOQUINAS, a tribe of semi-civilized or Pueblo Indians of New Mexico, who occupy 7 towns lying between the Little Colorado and San Juan rivers, and between lat. 35° and 36° N. According to Gov. Bent's report in 1846, the tribe included 350 families and 2,450 souls. In the tables of the Indian population of the United States, Mr. Schoolcraft, in his "History and Condition of the Indians," places the number much higher. The following are the names of the towns with their population as stated by him: Oriva, 5,000; Sumonpavi, 1,500; Jnpavivi, 1,250; Manzana, 500; Opquive, 650; Chemovi, 750; Tanoquevi, 900; total 10,550. With one exception these people speak the same language, "but are reputed," says Mr. Schoolcraft, "to be separate, distinct, and independent republics; though for mutual

protection they join with each other." Dr. Ten Broeck, of the U. S. army, who was among this people in 1852, and who has given an account of them in Schoolcraft's work, vol. iv., states their number as 8,000. Like the other Pueblo tribes, they cultivate various kinds of grain, fruits, vegetables, and cotton, and raise horses, mules, asses, sheep, and goats. Capt. Sitgraves, in his report published in 1854, states that the Moquis had more than 10,000 acres of Indian corn planted. In former times they were much more numerous than at present, according to their own statement, as well as to the early Spanish writers. Disease and their wars with the Navajoes, a large and powerful tribe, hostile alike to all the Pueblo Indians, have greatly decreased their numbers. Their villages are all upon bluffs in the same valley. "Three of them stand," says Dr. Ten Broeck, "upon a bluff about 300 feet high, and from 80 to 150 feet wide, which is approached by a trail passable for horses only at one point. This is very steep, and an hour's work in throwing down the stones with which it is in many places built up, could render it inaccessible to horsemen. At all other points they have constructed foot paths, steps, &c., by which they pass up and down." "There is a 4th town at 20 m. distant W. by S., and 2 more about S. S. W., and some 8 or 10 m. distance from the first 3. Of these, the two at the southern extremity of the bluff are the largest, containing probably 2,000 inhabitants. They all speak the same language except Harno, the most northern town of the 3, which has a different language and some customs peculiar to itself. It is, however, considered one of the towns of the confederation, and joins in all their feasts." Dr. Ten Broeck thinks it "a singular fact that this town, only 150 yards distant from the middle town, should have preserved for so long a period its own language and customs." The probability is that, like the Coco-maricopa tribe of the Gila, which removed to the vicinity of the Pimo tribe, where their villages adjoin, and who speak languages totally different, the inhabitants of the Moqui village of Harno took up their abode where they are now established for protection. Lieut. Col. Eaton, in his account of the New Mexican Indians (Schoolcraft, vol. iv.), says he was told at Zuni, that the 7th Moqui village was from the pueblo of Taos Indians on the Rio Grande.—The houses of the Moquis are built of stone, laid in mud, probably brought from the plain below, and in the same form as those of the other Pueblo Indians. These consist of several stories built up in the form of terraces; i. e., with one story receding from the other so as to leave a walk or terrace in front. On the lower or ground floor there are no doors or windows, access being had by ladders to the first terrace or roof, and then down through trap doors to the first tier of apartments. The ladders are drawn up at night or when they apprehend danger. The second and upper stories are also reached by ladders from the terrace,

there being no stairways or openings from one story to the other. The dress of the Moquis consists of leggings of dressed skins, sometimes made into boots. Sandals are also worn. Blankets of their own manufacture, some of wool and others of cotton, are worn by both sexes; but during the summer, like all other Indians, the men prefer to go naked, wearing merely a breech cloth round their loins, with moccasins or sandals to protect their feet. In their head dress they are fond of displaying their ornaments, and show much taste in their arrangement. The unmarried women turn their hair up on each side of the head in two inverse rolls, which bear some resemblance to the horns of the mountain sheep. After marriage they wear it in two large knots or braids on each side of the face. The women in the northern town vary their dress and mode of arranging their hair, which is another evidence that they belong to a different tribe. Their pottery resembles that of other Pueblo Indians, in its manufacture and ornaments. Dr. Ten Broeck gives the following account of their mode of marriage: "Instead of the swain asking the hand of the fair one, she selects the young man who is to her fancy, and then her father proposes the match to the sire of the lucky youth. This proposition is never refused. The preliminaries being arranged, the young man on his part furnishes two pair of moccasins, two fine blankets, two mattresses, and two sashes used at the feast; while the maiden, for her share, provides an abundance of eatables, when the marriage is celebrated by feasting and dancing. Polygamy is unknown to them; but at any time, if either of the parties become dissatisfied, they can divorce themselves and marry others. In case there are children, they are taken care of by their respective grandparents." They are a simple, happy, and hospitable people. They have no fermented liquors. They knit, weave, and spin, and make fabrics of cotton. Their pipes are made of a smooth polished stone and of a peculiar shape, which has long been in use among their ancestors. They wear necklaces of a very small sea shell, ground flat, probably procured from California, as they say they were brought them by Indians who lived over the mountains to the west.—Coronado with his companions visited these people in 1540, and describes their manners and customs, houses, agriculture, &c., precisely as we now find them, whence it is evident that they did not derive their civilization from the Spaniards. Venegas, in his "History of California" (1755), says that efforts were made by order of the viceroy of Mexico in 1728 to reduce the province of Moqui to subjection, its inhabitants having previously been converted by the zeal of the Franciscans; but in 1680 they apostatized, and, after killing the persons who instructed them, revolted, together with the other Indians of New Mexico. The fathers succeeded in restoring tranquillity among the various tribes, the Moquis alone excepted; "but all their diligence," says Venegas, "could

not overcome the obduracy of the Moquis, who for many years opposed all offers of their coming among them."

MOQUIN-TANDON, HORACE BÉNÉDICT ALFRED, a French physician, born in Montpellier, May 7, 1804. He studied the natural sciences under Duval, De Candolle, and Auguste St. Hilaire, was graduated as physician in 1822, appointed professor of comparative physiology at Marseilles in 1829, and officiated as professor of botany and director of the botanical garden at Toulouse from 1833 to 1853, when he succeeded M. Richard in the chair of natural history at the faculty of Paris and in the superintendence of the garden belonging to that institution. In 1854 he was admitted as a member of the botanical section of the institute, as successor of Auguste de Jussieu. At Toulouse he was one of the 40 members of the academy of floral games, which are still annually celebrated in that city, and familiarized himself with the Provençal dialect to such an extent, that his *Corys Magnolonensis* ("The Nut Tree of Magnelonne," Toulouse, 1836; 2d ed. with French translation, 1844), which he published as a Provençal legend, was accepted by M. Raynouard and other eminent Provençal scholars as a genuine production of the ancient troubadours, until M. H. Fortuiat revealed the truth concerning it. His principal work is *Éléments de tératologie végétale, ou histoire abrégée des anomalies de l'organisation dans les végétaux* (Paris, 1841).

MORA, JOSÉ JOAQUÍN DE, a Spanish author, born in Cadiz about 1784. He is the son of a magistrate of that city, and was educated at the university of Granada. He joined the army after the French invasion, and fell into the hands of the enemy, who detained him at Aix, where he married a French lady. On his return to Madrid in 1814 he established himself as a lawyer, and became the editor of various literary reviews. In 1820 he translated Jeremy Bentham's address to the cortes into Spanish. In 1828, on the restoration of the absolutist government, he repaired to England, where he supported himself as a book agent for various South American states, and by contributions to several illustrated publications. His efforts in supplying the South Americans with Spanish works procured for him in 1827 the editorship of the official journal of Buenos Ayres. Afterward he exerted considerable influence in Chili as director of the Chilian lyceum, as a journalist, and as under-secretary of state, in which capacity he drew up the present constitution of Chili. He was also instrumental in the promulgation of the Chilian free trade tariff of 1833. He spent some time in lecturing on Scotch philosophy and on other subjects in Peru, and was associated as private secretary to Gen. Santa Cruz in Bolivia from 1834 to 1838, when he returned to London as consul-general of the Peru-Bolivian confederation. In 1843 he returned to Spain, directing for some time the college of San Fernando at Cadiz. Having previously been Spanish consul-general in London, he was reappointed

to this office in 1856, and held it several years. He is a member of the Spanish academy, and by his translation of "Ivanhoe" and the "Talisman" he was the first to familiarize the Spaniards with the writings of Walter Scott. He is the author of a "History of the Arabs" (*Quadro de la historia de los Arabes*, London, 1826) and of other prose works; but his literary fame rests chiefly on his *Leyendas Españolas*, or Spanish legends (London, 1840), and on his lyrical poems in Wolf's *Foresta de rimas modernas Castellanas*. According to Wolf he excels most as a satirical poet. He also edited in 1848 the works of Luis de Granada in a collection of the Spanish classics.

MORAL PHILOSOPHY, or **ETHICS** (Lat. *mos*, Gr. *ἦθος*, manner, practice), the science of duty; the principles which prescribe what ought to take place in human conduct and actions. The ancient Greeks divided philosophy into logic, physics, and ethics; the first treated the universal and necessary forms of thought; the second, so much of the subject matter of thought as pertains to material nature; and the third, the whole nature and activity of free and intelligent beings. More precisely defined, ethics is that division of practical philosophy comprehending the doctrines of the right in human life, and is distinguished from policy and æsthetics, which embrace respectively the doctrines of the expedient and the beautiful or noble. Or it may be defined as natural in distinction from civil jurisprudence, treating of the relations, rights, and duties by which the members of universal society are by the law of nature under obligation toward God, themselves, and each other. Ethics regards mental dispositions; jurisprudence outward acts. The former extends to all moral qualities; the latter is limited to the virtue of justice, since no written law can enjoin gratitude or generosity. Moral law is imposed by the conscience; civil law by the decree of the legislator. Right is what a man may lawfully or morally do. Duty is what he must morally do. Crime is what he lawfully must not do. Vice is what he morally must not do. The law of nature, or the law of God, embracing the law of nations, is sometimes used as comprehending the whole of morality, the whole theory of conduct, and sometimes as containing only those unwritten rules of justice which are enforced by punishment in civilized countries, and at the breach of which it would be generally thought, if there were no government, that men might defend themselves by violence. Positive law, natural law, and moral law have been termed the three ascending degrees in the whole science of duty. The first inquiry in moral science is after an ultimate rule, a supreme principle of life, which shall be of imperative and universal authority, and around which shall be grouped all the motives and maxims of action. From this central principle every ethical system receives its character. These systems may be ranged in two classes, according as the ultimate moral rule is

objective or subjective, dependent on something without or within the mind. The most prominent objective theories are those which adopt as the ultimate principle and basis of morality: 1, the authority of the state; 2, the revealed will of God; 3, something inherent in the nature of things; 4, the greatest happiness. Hobbes maintained the first, and Descartes the second. To the third division belong Dr. Samuel Clarke's theory of the fitness of things, Wollaston's of the truth of things, Wayland's of the relations of things, and President Edwards's of the beauty in the union or consent of one mind with the great whole of being, in the love of being in general. To the fourth division belongs the Epicurean theory of personal pleasure, which was made to coexist with virtue by Aristotle, to which Paley gave a more religious aspect by weighing future eternal happiness against present self-renunciation, and which Bentham advanced with reference to public utility and the greatest good of the greatest number. The principal subjective theories find the essence and test of morality in: 1, natural susceptibility to pride, gratified by flattery; 2, an inner reciprocal sympathy; 3, an inner sense, which gives moral distinctions; 4, an immediate intuition. Mandeville defined virtue as the offspring of flattery begotten upon pride, its motives being vanity, and its object praise. Adam Smith urged that the ground of morality was a reflex sympathy, by which the observer changes place in thought with the actor, and affirms the action to be right or wrong according as it receives or repels his sympathy. Shaftesbury and Hutcheson maintained a distinct and specific moral sense, which immediately apprehends moral distinctions, and is to each man the source of obligation and the measure of virtue. Dr. Brown modified this theory by denying the existence of virtue and vice in the abstract, and claiming that a universal sentiment, by reason of the original conformation of the human mind, approves certain intentions and affections as right, disapproves others as wrong, and is the ultimate source of all moral truth. Fr. von Schlegel regarded this moral sense or universal sentiment as an inward revelation, which is in us but not of us, which is a divinely awakened awe of the Supreme Being, and which enjoins obedience to every form of God's commandments. Those who claim an immediate intuition of moral truth suppose in the human mind a higher reason for the apprehension of universal and necessary principles. The reason immediately beholds the right, and is of ultimate and conclusive authority. Its affirmation, founded on intellectual intuition, is the sufficient sanction of duty. Such, with various modifications, is the theory of Cudworth, Kant, and Coleridge.—Ethics is not, like mathematics or metaphysics, an independent science. It rests upon philosophical or theological principles, only the application or operations of which it deals with. It takes a dynamical and not a statical view of the elements of life. It pre-

supposes human liberty, the power to employ our mental and physical capacities as we will, and to determine the end toward which they shall be directed; for otherwise the sentiments of duty and of responsibility would be without foundation, would at most be mere phenomena of the consciousness, and moral philosophy could be only the natural history of human actions. Its distinctive quality would be lost, destiny taking in it the place of duty. The supremacy of the conscience, however it be defined, whose mandate is duty, is also presupposed, since a moral nature is prerequisite to the science of moral action. Conscience implies a supreme law, having reference to a general end, and constituting an ultimate rule of right, the determination of which, and its application to all departments of conduct, are the tasks of moral philosophy. A complete moral system states the supreme good of man, the supreme moral principle which should guide his action, and his particular duties to himself, to mankind, and to God.—Christian ethics is the doctrine of Christian life, embracing so much of dogmatics as pertains not to knowledge but action. Schleiermacher, Rothe, and others have regarded it as identical with dogmatics, on the ground that Christian faith and morals, thought and purpose, knowledge and action, are not separable. It differs from philosophical ethics in its subject, which is not man, but Christians; in its principle, founded on the recognized relation between man and God; in its source, being derived not from the reason, but from the teaching of Christ and the apostles; and in our perception of it, which is not by any analytical process, but by the Christian consciousness.—The earliest ethical speculations in Greece appear in the maxims of the gnomie poets. The first attempt to introduce a scientific analysis into the details of practical wisdom was that of Pythagoras, whose moral system was linked with a mysterious symbolism of numbers. Of oriental origin, the Pythagorean discipline has been likened to philosophy on a tripod; it taught by symbols, spoke in tropes, wrote in verses, and, instead of reasoning, uttered oracles. Its elementary ideas are those of unity and duality, the finite and the infinite, the right and the oblique, to the former of which corresponds good, and to the latter evil. From unity the harmony of numbers is derived, and the sovereign good is the rhythmical order of nature. When the principle of unity predominates in intelligent beings, there is spiritual harmony; and as harmony is not unity, but only an imitation of it, so virtue is not absolute goodness, but only an imperfect representation of it. God is the absolute unity, and is alone wise, and to imitate him as far as possible is the duty of all imperfect beings, who cannot be wise, but only philosophers or friends of wisdom. The Pythagoreans distinguished the animal soul, whose seat is the heart, and the rational soul, which abides in the brain, and gave to the latter the supremacy. They, therefore, laid stress on

self-command and temperance as essential to the vision of truth, and tended to ascetic practices, yet maintained that justice and love were inseparable, and were unsurpassed by any school of antiquity in urging the duties of friendship. The Pythagorean aristocracy resembled an oriental sacerdotal caste, and the Pythagorean political institutions in southern Italy mark the conflict between the genius of the Orient and that of Greece, between theocracy and humanity, the nobility and the people, the servitude of tradition and liberty of thought. Heraclitus repeated Pythagoras, and Democritus opposed him, founding the sensualist ethical school, and developing the most complete and scientific moral system prior to Socrates, which was, however, only a corollary and result of his atomic physical doctrines. The sovereign good of man, according to him, is not pleasure but happiness, which consists in constant and tranquil content. To be at once temperate, daring, and confident, and having never done nor wished anything absurd, to trust in fortune, was the whole purport of his ethical maxims. The age of the sophists succeeded. They, however, neither formed a school, nor their doctrines a system. Grammarians, rhetoricians, statesmen, metaphysicians, and moralists, from all the schools of Greek philosophy, their special influence was in inspiring respect for intellectual attainments and performances, and their best service was in habituating the Greek mind to a free examination of all human knowledge. The weapon which they wielded was a rhetorical eloquence under the sway of which the mythological divinities began to lose their majesty, the ancient traditions which had charmed successive generations ceased to have authority, the institutions of state tended toward equality and toward a foundation of reason instead of experience, and the enthusiasm of Greek culture was transferred from martial and political accomplishments to the arts, letters, and oratory. Their method was powerful to destroy rather than build up, yet the common statement that they were intellectual and moral corrupters is elaborately disputed by Mr. Grote. He regards them as the regular exponents of Greek morality, neither above nor below the standard of the age, maintains that Socrates was not their great opponent but their eminent representative, that they were the authorized teachers, the established clergy of the Greek nation, and that Plato was the dissenter, who attacked them not as a sect but as an order of society. Socrates is usually styled the father of moral philosophy; yet he was rather a sage than a philosopher, and is renowned rather for his wonderful moral consciousness and for his power of exciting the analytical faculties of others than for his positive speculative thought. He affirmed the reality of the distinction between good and evil, that it was founded in nature and not in convention, yet he did not precisely determine wherein it consists. He enjoined the supremacy of duty, yet he gave no objective or subjective definition of virtue. His highest

motive was to make reason prevail in human life, public and private, as it prevails in the universe. The elements of his instruction were: a supreme Deity, the principle of order and beauty in nature, and of justice and truth in man; and a series of human virtues, the principal of which were wisdom or a participation in the divine intelligence, justice, which is conformity to universal reason, fortitude, which gives courage and strength to endure trouble and resist difficulties, and temperance, which subdues the passions and makes us capable of intellectual delights. He was the first to treat distinctly of ethical science, apart from cosmological and metaphysical speculations, and laid down the principle of individual and social security and happiness as the end to which all moral precepts have reference. Like the other moral philosophers of antiquity, he confounded ethics and politics, and was a preacher of virtue in the interest of the state.—The aim of Socrates was to reform morals, that of his disciple Plato was to generalize thought. The latter did not frequent public places to teach the excellence of virtue, but, with a mind whose natural function seemed to be the contemplation of the essence of things, he disdained the shadows of earth for the eternal and divine realities of an ideal world, and developed schemes of thought which caused the fathers of the church to recognize him as one of their precursors. His fundamental ethical principle rests upon the antagonism of the visible and the invisible, the divine and the earthly. Man is in exile upon the earth, to which he is united by his senses and passions; but by his pure intelligence, his love, by dim reminiscences and regrets, he communes with heaven, which is his true home. He thus by opposite faculties and impulses tends to opposite goals. By yielding to the one he degrades himself, and to some extent perishes. By cherishing the other he resumes and retains his divine excellences. The four cardinal virtues are temperance, courage (*θυμος*), wisdom, and love. The first two are relative, the product of earthly imperfection; the second two are real, the remnants of our original perfection. They all have their foundation in wisdom, the fruit of reason, which sees through the material world the world of ideas of which it is a dim copy, and contemplates the supreme beauty of the essential universe. The Platonic morality is therefore speculative; virtue is referred finally to the intellect. A magnificent ideal is presented, the sentiment of love is commanded, and it is assumed that to know the right will be sufficient to practise it. There is no place in his philosophy for that perversity by which the soul sees the better and follows the worse, avoids what it loves and embraces what it hates—a phenomenon, however, which Plato himself has described. The virtue which won his admiration implies a pure intelligence, the obedience to which of the heart and will is presupposed. Nor did he precisely define the nature of moral good and evil; his analysis did not reach to the abso-

lute; and he left truth, beauty, and goodness to blend together and lose themselves in their supreme source. God is the principle of moral order, and virtue consists in the knowing and imitating him. "Alone among the ancient philosophers," says St. Augustine, "Plato made happiness consist not in the enjoyment of the body or the mind, but in the enjoyment of God, as the eye enjoys the light." The principle of the ideal contained in his philosophy has proved itself imperishable, and has more than once in modern times prompted both ethical and metaphysical speculations to higher standpoints.—The ethics of Aristotle place the sovereign good in happiness, which is inseparable from virtue, and consists in life and action. The gods themselves are happy only because they act. This theory of activity, which makes virtue to be the best possible disposition of all human functions, was one of the remarkable amendments made by him in the system of his master. An action is right or wrong only when it proceeds from free will and personal responsibility, and its moral desert must be judged by the end which it proposes, that is, by the intention. The Socratic and Platonic mistake of regarding vice as the involuntary product of ignorance is thus corrected. Virtue is a habit, a sort of moral dexterity; single acts cannot constitute it; but the virtuous disposition must be constant, acquired by oft repeated acts, and underlying the whole art of life. But his characteristic ethical statement is that virtue is a mean between two extremes. At one point all the passions are good; below or above that, they violate the order of nature, and are bad. Equally removed from extreme excess and extreme deficiency there lies in all spiritual and physical conditions an intervening state, which is that of virtue. To act when we ought, in the right circumstances, in the proper manner, and for legitimate persons and purposes—that is the *juste milieu* which characterizes morality. Hence there is always only one way of acting well, but thousands of making a mistake. He however gives no absolute definition of virtue, as an abstract mean between two abstract extremes, does not determine it as a fixed mathematical point, but makes it relative to the circumstances and disposition of the individual, a centre varying according to the pains and pleasures, desires and hatreds which encircle it. This ingenious theory is derived *a posteriori* instead of suggested *a priori*, is an inference and not an instinct, and has perhaps never been applied as a practical criterion of duty. As in metaphysics Aristotle completely sundered God from the world, so in ethics he separated the speculative from the practical reason, and gave to morality no foundation in absolute science. His moral scheme was a branch of politics, virtue was a civil quality to be developed only in the state, and his views of man and life were not universal but essentially Greek and republican. To prove that man was something more than a member of society was a task for the future.—This task

was fulfilled by cynicism and stoicism, while the conquests of Alexander may be said to have denationalized the Greek ethica. Diogenes proclaimed himself a citizen of the world, and the government of the universe the only polity worthy of our admiration. Opposed to patriotism, family, and property, the cynic placed virtue in the strength to endure privations and in independence of social relations. Under the banner of inward freedom and power, he verged toward asceticism, misanthropy, and impudence. The same tendency more strikingly appears in stoicism, the leading feature of which is tyranny over self, a revolt against the senses and passions, contempt of pain, pleasure, death, and of all the accidents of humanity. It was the philosophy of Roman citizenship, lying underneath the inflexibility of discipline and duty. Cleanthes and Epictetus both declared force to be the only virtue. A rigorous adherence to the essential elements, the lowest terms of human nature, a contempt for pleasure as something not designed in the scheme of natural law and inconsistent with its ideal of the freedom and independence of the soul, a striving to shape the individual life according to the rational nature, which is itself in conformity with the rational order of universal nature, an abstract apprehension of virtue as the subjection of personal to universal ends, and a consequent moral indifference to external good, were the prominent characteristics of the ethical system of the stoics, which was rivalled only by Epicureanism in the amount of its influence on Greek and Roman thought and life. Its moral standpoint was one of abstract subjectivity, its scheme of particular duties was conceived with reference to an ideal of rational freedom, and its motives were all heroic. Stern, haughty, and inflexible, it disregarded the lighter graces both of inward and outward nature in its contemplation of the laws and the energy of the primitive forces of the soul. Stoicism was one of the modes of reaction against the degeneracy of Greek society; Epicureanism, another. Like Aristotle, Epicurus placed the highest good in happiness. The prize of life is the possession of supreme pleasure. All other virtues are but the auxiliaries of prudence or wisdom, which is the architect of our happiness, teaching us in whatsoever situation to derive from it the utmost advantages. Thus by prudence the wise man will abstain from the burden of public affairs and from marriage, will observe the laws of his country, acquire means to live with dignity and ease, practise sobriety and moderation, cultivate friendships, and aim after a life without a trouble (*arapaíia*). This serene pleasure he does not allow to be disturbed by fears of death or of the gods; for the gods live in changeless and blessed repose in empty space, undisturbed by any management of human affairs; and death is the end of all feeling, and not an evil to be dreaded, since when death is, we are not. His ethical system does not recognize any positive end of life, and proposes nothing higher than a state

of passionless repose; and from the multitude of his disciples during several centuries there proceeded no original thought and no preëminent man. The system itself degenerated, until it became strange that a philosopher who was proverbially blameless and temperate, who nurtured himself on barley bread and water, with which he boasted that he could rival Jupiter in happiness, should have been the founder of Epicureanism. The Horatian *nihil admirari* expresses the melancholy but not the sensuality of its later character. The influence of the Platonic and Aristotelian ethical theories declined; stoicism and Epicureanism remained as rival sects. During the first Christian centuries stoicism predominated in intellectual theories and philosophers of all schools, poets, historians, and rhetoricians, spoke like Seneca and Epictetus of the sacred love of the world, of the equity of man, of universal law, and a universal republic. Unlike the earlier philosophers, who had founded ethics on the system of the human faculties and passions with reference to their combined operation in the state, the Neo-Platonists gave a theological and mystical character to duty in connection with their doctrines of emanation. The object of life was to rise by processes of asceticism and ecstatic vision from the world of the senses into which we have fallen to our original home in the world of ideas and the virtues which mark the successive stages in this return are distinguished as physical, political, ethical, purificative, contemplative, and theurgic.—While all antiquity had made the sovereign good consist in escape from pain, either by virtue or by pleasure, Christianity by the mystery of the passion announced the divinity of sorrow. From this time until the rise of modern philosophy ethics cannot be separated from dogmatics. During a thousand years of theological speculations on the problems of life, no system of philosophical ethics was attempted. The characteristic element in Christian virtue is love. If the Christian ideal of perfect charity were realized, ethics and politics would alike be absorbed in a higher science. Prominent were the ideas of faith, hope, charity, and sacrifice in the age of the apostolic and church fathers, their basis remained from the first rather religious than speculative, notwithstanding the persuasion that in the reason enlightened by the Word was given a ground of union between objective revelation and subjective knowledge. Justin Martyr, "the evangelist in the robe of a philosopher," began to apply the forms of ancient ethical philosophy to Christian concepts of duty, and maintained human freedom by identifying the will and the conscience. Augustine, though aiming to emancipate Christian thought from antique influences, asserted the rationality of Christian morality, since it sprang from the absolute reason of Christ, who was the central idea in philosophy and the ideal of life. While Augustine and Pelagius were debating free will and sovereign grace, the same question was discussed in a different form by the last of

the pagan philosophers, Plotinus and Proclus. The former, in a scheme of universal and absolute determination, suppressed liberty; the latter urged that the essence of personality was liberty, that man was his own controlling demon, and used the terms autokinesy and heterokinesy, corresponding nearly to the autonomy and heteronomy of Kant. The most elaborate attempt to combine the moral ideas of Christianity and of Alexandrian paganism was made by the writings ascribed to Dionysius the Areopagite, which exerted great influence on later mystical theories. In the middle ages, mysticism, scholasticism, and casuistry successively presided over the doctrines of Christian morality. St. Bernard and St. Victor were the leading representatives of mysticism. The former has been surpassed by no author in his delineations of the worth and power of love. From him proceeded that passionate inspiration, which the monastery of St. Victor perpetuated through the middle ages, and which remains embodied in the "Imitation of Christ." The two pre-eminent Christian sentiments, according to him, are humility and love, both springing from the knowledge of ourselves. A sense of humiliation is the first experience when we duly regard ourselves, and this prepares for intensity of love, which in its highest degree is felt only with reference to God. The great masters of scholastic theological ethics were Peter Lombard, Thomas Aquinas, and Duns Scotus. The aim of all was to harmonize Aristotelianism and Christianity. The first completed the list of the seven cardinal virtues by adding faith, hope, and charity to the ancient series of justice, fortitude, temperance, and wisdom. The second fully developed the mediæval philosophy of virtue. He made the intellect the highest principle, and distinguished universal and special ethics, the former being that of perfect beings in heaven, the latter that of imperfect beings on earth. Duns Scotus opposed the primacy of the will to that of the intellect, and thus introduced a subjective element in place of the objective knowledge to which Aquinas had given prominence. While by the mystical method morality was referred to inner feelings, aspirations, and conflicts, and by the scholastic method was founded on systems of intellectual principles, the casuistical method assumed prominence, which limited itself to the determination of duty in particular cases (*casus conscientie*) in practical life. Numerous works of casuistry, some of them designed for the use of the confessional, were produced from the 13th to the 16th century, the principal of which were the *Astesana* by a Minorite of Asti, the *Angelica* by Angelus de Calvasio, the *Pisanella*, also called the *Magistrucchia*, by Bartholomew de Sancta Concordia in Pisa, the *Rosella* by the Genoese Minorite Trouamala, and the *Monaldina* by Archbishop Monaldus of Benevento. The *Astesana* treated in 8 books of the divine commandments, of virtues and vices, of covenants and last wills, of the sacraments, of penance and extreme unction, of

ordination, of ecclesiastical censures, and of marriage. The tendency of casuistry was to dissipate the essential unity of the Christian life in the technical consideration of a diversity of works, and it had begun to decline when it was revived and zealously improved by the order of Jesuits, and became their peculiar ethica. The doctrine of probabilities was developed by them in connection with it. Pascal and others assailed the indefiniteness and ambiguity of casuistical principles. The *Medulla* of Hermann Busenbaum, which is the basis of the *Theologia Moralis* of Liguori, attained the highest reputation as an embodiment of Jesuitical ethica.—In the conflicts of the 16th century, when sects, schools, and parties were confounded and transformed, moral philosophy was subordinate to theology and politics. Montaigne, who of all the writers of the time was most distinctively a moralist, pretended to no system. The conciliatory Melancthon proposed a definition of virtue which includes the special features of all the schools and creeds; Suarez maintained the traditions of scholasticism; and Luther, Bruno, and Bacon, as well as the later Descartes, prepared in different ways for the achievements of a new era. One of the relics of mediæval discussion was the foundation of natural law. The disciples of Aquinas made it depend on the nature of things; those of Scotus and Occam, on the authority of God. The former made it essentially a matter of the intellect; the latter, of the will. The former tended to establish morality as independent of the Deity, and to affirm the eternal distinction between right and wrong, even if God did not exist; the latter tended to conceive of the moral law as an arbitrary enactment, to regard nothing as good or bad in itself, and the command of a superior as the only foundation of moral distinctions. The ablest representative of the latter theory in modern philosophy is Hobbes. He denied that any thing is naturally right or wrong, affirmed that pleasure and pain are the only objects to be desired or avoided, and limited human selfishness only by the control of an absolute civil power, the necessity of which is proved by experience in order to prevent a state of universal warfare. Morality is thus an artificial and prudential arrangement, dependent on the command of the political chief, without which the only virtues would be force and cunning. On the contrary, Grotius maintained moral distinctions anterior to human convention, and established the law of nature and of nations as a special department in ethical science. The idea of natural law was more precisely determined by Pufendorf, who defined it as the precept of right reason among men mutually social, making a disinterested care for the advantage of society the first duty. It does not extend beyond the limits of this life, is limited to the regulation of external acts, and exists in the nature of things and in the eternal principles of the divine reason. Leibnitz disputed each of these three propositions. The theory of Hobbes was professedly opposed by Cumber-

land, who claimed the existence of certain natural laws, independent of experience, and cognizable by right reason, which prompt us to the exercise of moral and social duties. The eternal and immutable distinction of right and wrong in the mind of God, and as pure conceptions of the human reason, was sustained by Cudworth, and was the occasion of more precise speculations in England as to the mode or faculty by which we perceive the distinction. —The ethical writings of Malebranche were the most important produced in France in the latter part of the 17th century. Virtue he defines to be the love of universal order, as it eternally existed in the divine reason, where every created reason contemplates it. Particular duties are but the applications of this love. He substituted for the ancient classification of four cardinal virtues the modern distinction of duties toward God, men, and ourselves. Spinoza, according to his opponents, by denying liberty in man and God, by recognizing only one divine substance and the modes thereof, made morality impossible, notwithstanding his principal work is entitled *Ethica*. But by defining clear ideas as those of the reason and vague ideas as those of passion, and establishing it as the object of existence to attain to clear ideas, he succeeded, like most other moralists, in opposing reason to passion. The being of the soul is thought. To increase this, to rise to a greater reality, to preserve and exalt our essential nature, is at once the highest good and the highest virtue. Knowledge is happiness, which is not the reward of virtue, but virtue itself. To follow our desires is the law of practical life, and limitation, deficiency of might, is the only evil. But evil is merely a relative conception of our own, formed by comparison of things with each other; there is no idea of it with God, who is always in harmony with himself, acting according to the laws of his own essence. —In the 18th century moral philosophy rested in England chiefly on theories of disinterested feeling and the moral sense, in France on sensationalism and self-interest; and in Germany the followers of Leibnitz maintained the supremacy of the reason and the doctrine of ideal good. Shaftesbury was the first to employ the term moral sense, which, however, he did not define. Some of his intimations favor the theory of general benevolence proposed by Edwards. Wollaston's definition of virtue as conformity to the truth of things, which Dr. Clarke changed to the fitness of things, gives to it an intellectual foundation, since truth and fitness are intellectual conceptions. Morality thus becomes the practice of reason. Hutcheson developed the suggestion of Shaftesbury of a moral sense, and supposed conscience and taste to be separate faculties which immediately introduce us to the objects of aesthetics and ethics. But neither he nor Bishop Butler, after thus determining the subjective condition of virtue, undertook to show the objective distinctive quality common to right actions. Nothing

therefore but the immediateness of moral emotion and determination is secured by their theory, since neither the moral sense nor the morality of actions is explained by the statement that they correspond to each other. Adam Smith, in referring morality to the principle of sympathy, rendered a service rather to the philosophy of the sympathetic affections than of ethics. Though perhaps no one has ever accepted his statement that moral approval depends first upon sympathy with the motives of the agent, secondly upon sympathy with the gratitude of those who have been benefited by his actions, thirdly upon a perception that his conduct has been agreeable to the general rules by which these two sympathies generally act, and fourthly upon a perception of the utility and beauty apparent in a system of behavior which tends to promote the happiness either of the individual or of society; yet his analysis of the workings of sympathy is admirably conceived and illustrated. It was a part of Hume's ethical theory that general utility constitutes a uniform ground of moral distinctions. Denying a special moral faculty, he spoke sometimes of sympathy and sometimes of benevolence as the subjective quality which prompts us to be pleased with beneficial actions. Richard Price attempted to revive the intellectual in place of the sentimental theory of virtue, claiming that not only our moral feelings but all our emotions might ultimately be referred to the reason. He regarded right and wrong as simple ideas of the mind — The maxim of Rochefoucauld: "Our virtues lose themselves in interest, like rivers in the sea," describes the ethical theory of the French sensational philosophy. Condillac, the head of this school, regards all intellectual operations even judgment and volition, as transformed sensations; and Helvetius, applying the theory to morals, held that self-love or interest is the exclusive motor of man, denied disinterested motives, made pleasure the only good, and referred to legislative rewards and punishments as illustrating the whole system of individual action. A superior physical organization alone gives to man his superiority to other animals. La Mettrie maintained an atheistic Epicureanism; and though Condorcet proposed as a goal the perfectibility of mankind in the present state, he looked only to physical improvement, and wished to substitute an empirical education for the ideas and sanctions of religion and morality. The materialism, atheism, and fatalism of the epoch, which saw in the universe only matter and motion, and had pleasure for its single aim and law, were most completely and logically elaborated in D'Holbach's *Système de la nature*. —The influence of Leibnitz and Wolf maintained a higher philosophy in Germany, and the latter advanced the ethical principle that we should act only with reference to making ourselves or our world more complete and perfect. Moral perfection consists in the harmony of the present with the past and the future, and of ourselves with the essential nature of man. Whatsoever tends to

ward or against this is right or wrong. Thus ethics is the science of the possible in life, as philosophy is of the possible in the whole realm of knowledge. A eudæmonistic and utilitarian school succeeded in the latter half of the 18th century, marked by subjective idealism, which made individual culture and happiness the highest principle and end, and cherished religion on the ground that it was advantageous to earthly pleasure. Basedow, Reimarus, and Steinbart were the principal representatives of this tendency, the subjective standpoint of which appears also in numerous confessions and autobiographies, like those of Rousseau.—Kant rescued ethics from the prevalent sentimental and sensational theories. "If," said he, "happiness, and not the law of inward freedom, be made the fundamental principle, there is an end to moral science." He defines ethics as the philosophy of the laws of freedom. Freedom is an *a priori* fact, an element which affirms itself in the activity of the will. The will has the capacity of entire independence or self-determination, bound only by its own autonomy. The pure reason proposes to it a universal law, which we call the moral law, and which is a categorical imperative, requiring an unconditioned obedience. This law is, in Kant's phraseology, the form of human action. Desires, passions, and material motives furnish the contents of action, and their influence constitutes the heteronomy of the will. To exclude principles that are merely of a heteronomic nature, to admit only such motives as may be transformed into universal laws of the reason, so that the autonomy of the will may be inviolate, is the essence of morality. Thus the ethical law of Kant is: "Act only on such a maxim as may also be a universal law." A reverence for the moral law, which he compares to the starry heavens, a severance of the impulses of sense from moral motives, and an estimate of virtue as a triumph over resistance, characterize the Kantian morality. Sanctity is absolute conformity to the moral law, the ideal of moral perfection. Virtue is a constant tendency and progress toward this ideal. The supreme good is the highest happiness joined to the highest virtue. Since these do not correspond in the present state, the practical reason postulates for the attainment of the first the existence of God, and for the attainment of the second the immortality of the soul.—Personal autonomy becomes still more prominent in the philosophy of Fichte. According to him, the most profound and essential truth of our existence is the perpetual striving of the mind to develop itself, to realize its own nature, to bring into actual existence all that lies potentially in its consciousness. This fundamental impulse furnishes the formal principle of ethics, the principle of absolute autonomy, the self-formed aim of being. With it is associated the impulse of nature, which strives not for fulness and freedom, but for enjoyment. Both impulses aim at a unity, and their approximation is an infinite progression. "The world," says Fichte,

"is the sensized material of our practical life, the means by which we place before us, as object, the end and aim of our existence." Destiny is the course of the moral determination of the finite rational being. The formula of ethics is therefore: "Always fulfil thy destiny," which underlies the whole theory of particular duties. The conviction of duty, or conscience, is the condition of the morality of actions. A feeling of truth and certainty is the absolute criterion of the correctness of this conviction, and never deceives, since it exists only when the empirical is in harmony with the absolute Ego. In the later form of Fichte's philosophy, its moral strictness was relieved by religious sentiment, the elements of the Ego and duty being transformed into life and love. His formula, making morality the fulfilment of destiny, is akin to the theory of Aristotle, and was adopted by Jouffroy, the principal moralist of the French eclectic school. In ethics alone Schelling scarcely departed from the principles of Fichte. In the system of Hegel, jurisprudence, ethics, and politics form the three divisions of the philosophy of mind viewed objectively. The removal of the antagonism between the universal and the particular will constitutes morality. To pursue the rational, or what is in accordance with the universal will, is right; to pursue the irrational is wrong. The three spheres in which moral purpose appears are the family, civil society, and the state. The state is the ethical whole, the highest embodiment of the moral idea, and its will should be supreme over that of the individual. He thus recurs to the ancient notion of merging ethics in politics, gives to morality a foundation of civil absolutism, and regards the rise and fall of states as historical developments of special phases of the reason. Herbart resolved ethics into æsthetics. De Wette adopted Jacobi's principle of feeling as the moral lawgiver, and stated the formula: "Live in order to live, and out of pure reverence and love of life;" and Schleiermacher founded a system of ethics in which prominence is given to personal responsibility, and the invisible kingdom of God is made the highest good.—Against the doctrines of a moral sense and of disinterested benevolence which had chiefly prevailed in English ethical philosophy from the time of Hutcheson and Butler, and which were zealously defended by Dugald Stewart, a utilitarian tendency was manifested which culminated in Jeremy Bentham. Previous to him Tucker had developed a system akin to the selfish theory, founded on Hartley's principles of association; and Paley had declared the motive to virtue to be everlasting happiness, and had resolved the art of life into that of rightly settling our habits. Bentham gave to his moral theory the name of "the greatest happiness principle," and represented the practice of virtue as the art of maximizing happiness. All moral action proceeds, according to him, from the calculation of pains and pleasures, estimated by their magnitude

and their extent. In the proper balancing of these all morality consists, and virtue and vice are absolutely nothing, merely fictitious entities, when separated from happiness and misery. His aim was to expel from ethical science the word "ought," which was claimed by Mackintosh as the simplest and most universal expression of the moral sense. "The talisman of arrogance, indolence, and ignorance," says he, "is to be found in a single word, an authoritative imposture, which in these pages it will be frequently necessary to unveil. It is the word 'ought.' If the use of the word be admissible at all, it 'ought' to be banished from the vocabulary of morals." Till this is done he proposes to neutralize its effect by the use of another potent word—"why?" Yet Whewell has remarked that it is a mere assumption to prescribe that the answer to this query must be in the language of the utilitarian theory. Bentham urged the formation of general rules of conduct, and strict conformity to them, in order to avoid the temptations of our frailty and passions; and if a reverence for virtuous maxims and precepts thus take the place in the mind of the utilitarian of the direct application of his principle, there will be little difference between him and the believer in immutable morality, since the practical rules of both will coincide.—John Stuart Mill, who acknowledges the influence of both Bentham and Comte, in the latter portion of his work on "Logic" proposes and discusses the inquiry whether ethics may not be reduced to a certain science, and principles be as definitely established in the art of life as the indisputable laws of physics. He develops the subject no further than to state that happiness, in the full meaning of the word, must be the recognized goal of existence and aim of action.—The Italian school of philosophy of the present century presents the subject of ethics in new phases. Virtue, according to Rosmini, is founded on the idea of possible being. Universal being is the absolute good and the principle of every particular good. Moral good is the absolute good in so far as it is desired by man, since it is desire which first leads him to the idea of perfection, which is elaborated into that of being. The first precept of the moral law, therefore, is to love being as such. But as the moral act must be with reference to the ultimate goal and infinite object of thought, the formula is thus transformed: "Love intelligent beings, not for themselves, but for their supreme end, which is God." Virtue consists in the conformity of intuitive and reflex knowledge, and its essential principle is truth. Obligation rests on the power of rational decision on what a person knows. Conscience is a speculative judgment on the morality of the practical judgment and on its consequences. Mamiani, also, seeks in ontology the sources of moral order. According to him, "absolute good exists," a deduction from the idea of a first infinite cause, is the fundamental principle of ethica. Virtue is the voluntary

coöperation of free and rational beings in the moral order of the universe, in which consists the absolute good, and which converges to God. Deviation, on the contrary, is evil and sin. The moral law in most general terms commands "Do good." Duty requires the accomplishment of the part assigned to each individual in working out the supreme end of society. But beyond this fulfilment, there is a heroic virtue whose object is the greatest possible realization of good, and which consists in the appropriation of individual capacities to the general interests of society. Mamiani maintains, as a matter of history, that right intentions have never resulted in greater evil than good, but that by a preëstablished harmony even a false application of a truth must result in some undesigned advantage. The law of progress reigns in the moral as in the material world, and ultimate perfection in an immortal state is the goal of humanity. Gioberti defines virtue to be the knowledge of an absolute law and the conformity of a free will to that law. Law is an idea considered in reference to the will, and an ethical must be founded on a metaphysical system. An ultimate law cannot be considered independently of religion, because it is in fact God himself. The divine will manifested in the moral imperative appears clothed with an absolute right. God as the absolute law reigning over the free human will is the condition of obligation. The ideal formula of Gioberti transferred to the department of ethics becomes: Being, by means of the human will, creates the good. The human will, preferring law to affection, creates virtue. Virtue, reconciling affection with law, creates happiness. All these Italian systems of ethics recall the ancient speculations on the subject by referring virtue ultimately to the intellect, making ontology a conception of being the foundation of responsibility. They also connect virtue closely with religion, and give to it something of an ecclesiastical character.—See Meinera, *Allgemeine kritische Geschichte der älteren und neueren Ethik* (1800-'1); Möller, *Das absolute Prinzip der Ethik* (1819); Staädlin, *Geschichte der Moral-Philosophie* (1822); De Wette, *Christliche Sittenlehre* (1819-'28); Henning, *Prinzipien der Ethik in historischer Entwicklung* (1824); Vetter, *Ueber das Verhältniss der philosophischen zur Christlichen Sittenlehre* (1824); Daub, *Vorlesungen über die Prolegomena zur theologischen Moral, und über die Principien der Ethik* (1839); Wirth, *System der Speculativen Ethik* (1841); Rothe, *Theologische Ethik* (1845); Fuchs, *System der Christlichen Sittenlehre* (1850); Gioberti, *Del buono* (1843); Kantain, *Philosophie morale* (1842); Denis, *Histoire des théories et des idées morales dans l'antiquité* (1855); Janet, *Histoire des idées morales et politiques* (1856); Mackintosh, "Dissertation on the Progress of Ethical Philosophy" (1830); Blakey, "History of Moral Science" (1840); Whewell, "History of Moral Philosophy in England" (1852); Wayland, "Elements of

Moral Science" (1835); Alexander, "Outlines of Moral Science" (1852); and Hickok, "Moral Science" (1853).

MORALES, AMBROSIO, a Spanish historian, born in Cordova in 1513, died in Alcalá in 1591. After studying at the universities of Salamanca and Alcalá, he entered a Jeronymite convent near Cordova, under the name of Ambrosio de Santa Paula. He subsequently became a professor at Alcalá, and, on the death of Florian de Ocampo in 1570, was appointed historiographer to the crown of Castile. In this capacity he wrote a continuation of Ocampo's *Cronica general de España* down to the period of the union of the crowns of Castile and Leon (1037). The best edition of it is that published at Madrid in 1791, in 6 vols. 4to. Southey calls Morales "the Camden of Spain."

MORAT (Germ. *Murten*), a town in the Swiss canton of Freyburg, on the S. E. shore of the lake of Morat, and on the high road from Bern to Lausanne, memorable for the victory achieved there by the Swiss confederation over the formidable Burgundian army under the duke Charles the Bold, June 22, 1476. An obelisk was erected on the battle field in 1822. (See *BERGUNDY*, vol. iv. p. 116.)

MORATIN, NICOLAS FERNANDEZ, a Spanish author, born in Madrid, July 20, 1737, died there, May 11, 1780. A lawyer by profession, he was the reformer of the Spanish theatre, and, with the aid of a royal injunction, drove the miracle plays from the stage. He was the author of a comedy called *Petimetra* (1762). He published in 1764 his *Poeta*, consisting of short poems, followed in 1765 by the *Diana*, a didactic poem, and a narrative poem on the "Destruction of his Ships by Cortes." His best tragedies are *Lucrecia* and *Hormesonda*. He also wrote in prose on historical subjects. A complete collection of his works has never been made. In 1821 his son published a volume of posthumous poems, together with a life and some of his more celebrated lyrics. His dramas and prose works are extant in pamphlet form.—LEANDRO FERNANDEZ, son of the preceding, a Spanish dramatist, born in Madrid, March 10, 1760, died in Paris, June 21, 1828. He was apprenticed to a jeweller, and worked at that trade till he was 23 years old. While a child, however, he wrote verses, and at 18 obtained the second prize of the academy for a poem on the taking of Granada. In 1780 he published a satire entitled *Leccion poetica*, and in 1787, by the intervention of Jovellanos, he was made secretary to the Spanish embassy at Paris. On his return to Madrid, he published several small pieces in prose and verse, and under the patronage of Godoy was sent at the public charge to study the drama of Germany, England, Italy, and France. On his return an office in the department of foreign affairs was assigned him. About this time he published a translation of Hamlet, *El baron, a mojigata*, and *El si de las niñas*, the most popular of his plays, performed for 26 nights

consecutively, reprinted 4 times in the same year, and translated into many languages. The French invasion of 1808 brought him into misfortune, and on the restoration of Ferdinand VII. his property was confiscated; but in 1814 he was again received into favor. He went back to France in 1817, but in 1820 he returned to Barcelona, where he edited his father's works, and afterward established himself in Paris. He died in poverty; his remains were removed to Madrid in 1853. A complete edition of his works has been published by the academy of history at Madrid.

MORAVIA (Slav. *Morawa*; Germ. *Mähren*), a margraviate and German crown land of Austria, situated between lat. 48° 40' and 50° 20' N., and long. 15° 10' and 18° 28' E., bounded N. and N. E. by Prussian and Austrian Silesia, E. and S. E. by Hungary, S. by Lower Austria, and W. and N. W. by Bohemia; area, 8,560 sq. m.; pop. about 2,000,000. The country is mostly mountainous, the principal ranges being the Moravian mountains, the Sudetic range with its eastern continuation the Giesenke, and the Carpathians, which respectively separate it from Bohemia, Silesia, and Hungary. The central mountains, between Brünn, the capital, and Olmütz, contain numerous caverns. The valleys and the southern districts, which are mostly level, are fertile. Moravia is traversed by numerous rivers, the principal of which are: the March or Morawa, which rises in the northern corner of the country, flows in a S., S. E., and S. W. course through its entire breadth, receiving almost all other water courses, and, after having formed a part of the Hungarian boundary, falls into the Danube; the Beczwa, E. of the March, and the Hanna, Zwittawa, Schwarza, Iglawa, and Taya, W. of it. The Oder, which flows N. E. into Silesia, has its head waters S. of the Giesenke range. The climate is comparatively mild. Moravia is in general very productive, yielding excellent grains and fruits, hemp, flax, and wine, and vast quantities of timber, iron, coal, marble, alum, vitriol, sulphur, lead, pipe clay, and some silver. The mines are of great antiquity, some of them having been known since the 8th century. The most productive are those of iron and lead. Gold and silver were formerly extracted to some extent, but little attention has been paid to these ores since the 16th century. The deposits of coal would repay much more labor than is now expended on them. The pipe clay, which in its natural state is so soft that it may easily be moulded by the hand, is much used for making meerschaums. Agriculture, grazing, manufactures, and trade are in a flourishing condition. Woollen, linen, cotton, thread, leather, arms, needles, domestic utensils, porcelain, pottery, glass, paper, beet root sugar, and chemical products are manufactured. Many railways intersect the country, connecting it with Austria, Bohemia, Silesia, and Galicia. The inhabitants are mainly of Slavie origin, including Slovaks on the confines of Hungary,

Hannaks in the fertile central region watered by the Havel, and the Cecho-Moravians in the districts adjoining Bohemia. The Germans and Jews mostly inhabit the towns, the former being most numerous in the regions adjacent to Silesia and Austria. There are also some Wallachs and French. The bulk of the inhabitants are Roman Catholics, the number of the Protestants falling short of 60,000, and that of the Jews short of 40,000. Previous to 1848 the latter were subject to the most oppressive obligations and restrictions. The highest Roman Catholic prelate is the archbishop of Olmütz. The educational institutions of Moravia are very numerous, and the proportion of pupils exceeds that of almost all the other Austrian provinces. The highest scientific establishments are in Brünn and Olmütz. These two cities, the one situated at the confluence of the Schwarza and Zwickawa, and the other on the March, are also the capitals of the two chief administrative divisions of Moravia. Other important towns are Znaim on the Taya, Iglau on the Iglawa, Prosnitz in the Hanna district, Prerau on the Beczwa and at the junction of the Vienna and Breslau and Vienna and Olmütz railways, Kremsir on the March, Austerlitz E. of Brünn, and Nikolsburg S. of the Taya.—Before the close of the 6th century the country was successively occupied by the Quadi, the Rugii, Heruli, and Longobardi, and in the following period by Slavic tribes, who, after the decline of the kingdom of the Avars, founded the empire of Great Moravia, the name being derived from the river Morawa (March). Charlemagne conquered it, and he and his successors exacted tribute and the adoption of Christianity, of which St. Cyril became the great apostle among the Moravians. Swatopluk, who rebelled against the German emperor toward the close of the 9th century, made Moravia a powerful state; but it soon after succumbed to the combined attacks of the Magyars and Germans. Moravia was now often invaded by Poles, Magyars, Cechs, and Germans. In the 11th century it was attached to Bohemia, and about the end of the following century constituted a margraviate of the empire, though dependent as a fief upon the Bohemian crown. After numerous divisions, it came together with Bohemia into the possession of the house of Hapsburg by the death of King Louis II. of Hungary and Bohemia in the battle of Mohács (1526), his crowns being inherited by Ferdinand I. of Austria. The Austrian constitution of 1849 made it a separate crown land, as well as Austrian Silesia, which was formerly united with it, and the statistics of which are therefore omitted from this article.

MORAVIANS, also called UNITED BRETHREN, or the *UNITAS FRATRUM*, a church of evangelical Christians, historically and ecclesiastically distinct from the society of the "United Brethren in Christ," with whom they are often confounded. Their history proper begins with the year 1457, 60 years previous to Luther's reformation; but their preparatory history extends back

as far as the 9th century, when Christianity was introduced into Bohemia and Moravia by missionaries who came from countries in which the apostle Paul had preached the gospel and founded churches. For several centuries it is claimed that the people of Bohemia and Moravia manifested, in matters of faith, the spirit of what was afterward Protestantism, holding fast to ecclesiastical principles opposed to the conjunctions of the Roman Catholic church, and submitting to the Bible as the only rule of faith and practice. The most celebrated of their reformers was John Huss (born 1373), who was burned at the stake by order of the council of Constance in 1415. As soon as the news of his death reached his native country, fierce disturbances broke out. A powerful party arose, called the Hussites, who waged war for a number of years with great fury against the imperialists. After a time the Hussites separated into two factions: the Calixtines, who insisted principally on the restoration of the cup to the laity in the Lord's supper; and the Taborites, whose aim was a general reformation of the whole church. In 1433 the council of Basel granted the celebrated "compacts" to the Bohemians, by which the most essential of their demands were nominally conceded. The Taborites refused to receive these compacts; whereupon the Calixtines turned their arms against their brethren, and totally defeated them in 1434. The Calixtines were now the national church of Bohemia, and hostilities ceased. But a party among the remnant of the Taborites, dissatisfied with what they regarded as corrupt practices in this church also, withdrew more and more from the communion of the Calixtines, and through the instrumentality of the Calixtine bishop Rokyzan, who at first favored the movement, received permission from the regent of Bohemia to settle on one of his estates, known as the barony of Lititz. This was in 1456. A considerable number of persons under the leadership of Gregory, a nephew of Rokyzan, took up their abode on this estate. In the year 1457 they organized a religious society, adopted principles of discipline, elected 25 elders to govern the society, and took the name of "Brethren and Sisters of the Law of Christ," which was afterward changed to the simpler one of "Brethren." At a later period the title *Unitas Fratrum* or "Unity of the Brethren" was adopted. Their pastors were Calixtine priests who entertained evangelical views, and who had joined the society. Such was the beginning of the Moravian church. In 1461, at the instigation of Rokyzan, who had become their inveterate enemy, a fierce persecution burst upon the Brethren, many of whom suffered martyrdom. This persecution only served to increase the number of the Brethren; and in 1467 a synod was held at Lhota, a village on the estate of Lititz, for the purpose of effecting a more complete organization. After protracted deliberations the Brethren resolved to separate entirely from the national establishment, and to

change their society into an independent church. To do this, it was necessary to institute a ministry of their own; and being anxious to secure one whose validity the Calixtines and Roman Catholics would be compelled to acknowledge, they determined to seek the episcopal succession from a colony of Waldenses, settled on the confines of Bohemia and Austria, who had obtained this succession. The Waldensian bishop Stephen, and his assistants, consecrated three men, who had been sent to him by the synod of Lheta, to the office of bishop. As soon as these events became known, new persecutions broke out; but the Brethren continued to increase notwithstanding. Toward the close of the 15th century they had more than 200 churches in Moravia and Bohemia, had published a Bohemian version of the Bible and several confessions of faith, owned two printing establishments, and were preparing a catechism and hymn book for publication. In the 16th century they sent several deputations to Luther. There were differences of opinion between them and him in respect to discipline, on which the Brethren insisted very strongly; still their intercourse, for the most part, was friendly, and when the last deputation took leave of the great reformer he bade them God speed, in these words: "Do you be the apostles of the Bohemians, as I and my brethren will be apostles of the Germans." With some other of the reformers the Brethren stood in still closer connection. Meantime their numbers and influence increased very much. They established churches in Poland, and gradually the *Unitas Fratrum* was composed of 8 provinces, the Bohemian, Moravian, and Polish, each governed by its own bishops, but all confederated as one church, holding general synods in common. In the beginning of the 17th century, the outward prosperity of the Brethren was fully established; by the "letters of majesty" of the emperor Matthias, the *Unitas Fratrum* became one of the legally acknowledged churches of the land. A remarkable work, completed some time before, was the celebrated Bohemian Bible of Cralitz, translated from the original by a committee of bishops, after a labor of 15 years. But the period of outward prosperity did not continue long. In 1621 Ferdinand II. began a series of persecutions directed against all the Protestant denominations in Bohemia and Moravia, and known as the anti-reformation. His plans were successful. Protestantism was totally overthrown in these countries, more than 50,000 of whose inhabitants emigrated. The Brethren's church ceased to exist, except in Poland; and there, in the course of a few decades, it was united with the Reformed denomination. In this way the *Unitas Fratrum*, as a distinct organization, disappeared from the eyes of men, and remained as a "hidden seed," for a period of 94 years. This seed was fostered by John Amos Comenius, the last bishop of the Moravian line, who not only published several works by which the history, doctrines, and discipline

of the Brethren were preserved, but also provided for the continuance of the episcopate. In Moravia many families remained, which secretly entertained the views of their fathers. Among these an awakening took place in the first quarter of the 18th century, through the instrumentality of a Moravian exile named Christian David. In consequence of this awakening, the desire to live in a Protestant country was felt more and more. Just 50 years after the death of Comenius, in the night of May 27, 1722, two families of Moravians escaped from their native country, and, after a journey of 11 days, safely reached Berthelsdorf, an estate in Saxony belonging to Count Zinzendorf, a pious young nobleman, who had offered them a refuge. Other Moravians soon joined them, and in 5 years a colony of 300 persons lived on Count Zinzendorf's estate. They built a town, and called it Herrnhut; introduced the discipline of their fathers, preserved by the publications of Comenius; and in 1785 obtained the episcopal succession of the *Unitas Fratrum*. In this way the ancient church was renewed. Zinzendorf soon relinquished all worldly honors, became a bishop of the Brethren, and devoted himself entirely to their service. Churches were established in various parts of the continent, in North America and Great Britain. In 1749 the British parliament acknowledged the Moravian Brethren as an episcopal church, and passed an act encouraging them to settle in the North American colonies. They devoted themselves here to missions among the Indians with great success, one of their most celebrated stations being at Gnadenhütten ("tents of grace") in Tuscarawas co., Ohio, where 100 Moravian Indians were treacherously massacred by whites, March 8, 1782, on a groundless suspicion of having been concerned in certain outrages in Pennsylvania. The numbers of the Brethren, both in America and in Europe, never increased as did those of many other denominations of Christians. This was owing to two causes. First, almost the entire strength of the renewed Moravian church was concentrated on the foreign mission field. Secondly, the fundamental principle underlying the efforts of Zinzendorf and his coadjutors, on behalf of the church at home, was Spener's idea of *ecclesiolas in ecclesia*—little churches within the church—households of faith whose members should be separated as much as possible from the world, and which should constitute retreats where men could hold undisturbed communion with God. This idea, carried out consistently, resulted in the establishment of Moravian settlements, that is, towns founded by the church, where no one who was not a member was permitted to own real estate, although strangers, complying with the rules of the community, were allowed to lease houses. A system so exclusive necessarily kept the church numerically small, although it undoubtedly was of great advantage in other respects, and served to foster the missionary zeal which has distinguished the Moravians. During the last 20

years great changes have taken place in the United States in respect to this system, and also in regard to the constitution of the church generally. The last general synod, held at Herrnhut in 1857, remodelled the constitution, and opened the way for a more general development of the resources of the church in the home field. —The *Unitas Fratrum* now consists of 3 provinces, the American, continental, and British, which govern themselves in all provincial matters, but are confederated as one church in respect to general principles of doctrine and practice, and the prosecution of the foreign mission work. Each province has a provincial synod, whose executive is an elective board of bishops and elders, styled the "Provincial Elders' Conference," to which the entire management of the church in provincial things, including the appointment of pastors, is intrusted in the interval between two synods. For the general government of the 3 provinces and the foreign missions, there is a general synod, which meets every 10 or 12 years, and to which each province sends the same number of delegates. The executive board of the general synod is called the "Unity's Elders' Conference," and is the highest judicatory for the whole *Unitas Fratrum*, when that synod is not in session. In the American province there are two districts, the northern and the southern, each having a synod and a provincial elders' conference. The seat of government for the northern district is at Bethlehem, Northampton co., Penn.; and for the southern, at Salem, Forsyth co., N. C. The Moravian churches in these two districts, without exception, are now like those of other Christian denominations, the exclusive system having been given up entirely. The establishments formerly found in the settlements, and known as brethren's, sisters', and widows' houses, have likewise passed away. In the British province, the seat of government is at Ockbrook, Derbyshire. Only 4 of the churches of this province are settlements. In the continental province, the old system is kept up in all respects. The governing board, which is at the same time the general board for the whole "Unity" (the name by which the *Unitas Fratrum* is generally known in Moravian phraseology), has its seat at Berthelsdorf, a village on the estate of the same name, in Saxony, about a mile from Herrnhut; it assembles for business in the castle formerly inhabited by Count Zinzendorf, who devoted his entire property to the good of the church. To a Moravian settlement on the continent of Europe still belong the institutions mentioned above, which have been given up in this country, namely, brethren's, sisters', and widows' houses. In a brethren's house, unmarried men live together, and engage in various trades and professions, the profits of which go to the church; in a sisters' house, unmarried women reside, and have an opportunity of earning a livelihood by different kinds of female work; a widows' house is a house for indigent or other

widows, where they live comfortably at a very cheap rate. Each house has a spiritual and temporal superintendent, a common refectory and dormitory (except in the case of widows' houses), and a prayer hall, where religious services are daily held. There is nothing monastic in the regulations by which these establishments are governed. The inmates remain in them entirely as their own option, and are almost invariably such as have no other home. A community of goods never existed, at any time, in a Moravian church or Moravian institution. The contrary has often been supposed, owing to the circumstance that in the last century, during the Indian wars, when the settlements of the Brethren in America were yet feeble and exposed to the attacks of the savages, it became necessary to combine the efforts of all the members for the sustenance of the community. Hence the system of "common house-keeping," as it was called, was introduced; but each person retained his own private property, and when the wars were over and the settlements secure, the system was given up. It continued only for about 15 years.—The Moravians are an evangelical church, in the fullest sense of the term, as it is commonly used in the United States. They have no confession of faith as such; but the doctrines which they uphold are embodied in a catechism and a litany, called the Easter morning litany, and used on Easter Sunday. Catholicity eminently marks the church, in a doctrinal point of view. Its motto may be said to be that of Augustine: "In essentials unity, in non-essentials liberty, in all things charity." The distinguishing feature of Moravian theology is the prominence given to the person and atonement of Christ. He is regarded as the centre of Christian doctrine, "in whom all the promises of God are yea and amen, and in whom we have the grace of the Son, the love of the Father, and the communion of the Holy Ghost." The Moravian ministry, like that of the Protestant Episcopal church, embraces bishops, presbyters, and deacons. Bishops only have the right to ordain. They are usually appointed by lot, in imitation of the mode of appointing the apostle Matthias. The Moravian episcopacy is not prelatical; the bishops have no dioceses, and do not govern the church in virtue of their office, but only when elected to the governing boards. However, they are almost invariably members of these boards by election. The Moravian episcopal succession from 1467 to 1860 embraces 161 bishops. There are 16 bishops in office at present. Of these, 1 reside in Germany, 1 in Russia, 8 in England, 4 in the United States, and 1 in the West Indies. The ritual of the church is similar to that of the Protestant Episcopal. A litany is used, in several languages, in all the different parts of the Unity; and there are regular services for infant and adult baptism, the sacrament of the Lord's supper, the rite of confirmation and ordination, the burial of the dead, and marriage. Love feasts, in imitation of the apo-

tolical agapæ, are celebrated; and liturgical services, particularly on the occasion of church festivals, are held in many churches. The Moravians are distinguished for their church music.—The present numerical strength of the home church is as follows: in the American province there are 84 churches, 5,800 communicants, and 8,276 souls; in the continental, 19 churches (all of which with the exception of 4 are Moravian settlements), 4,677 communicants, and 6,174 souls; in the British province, 84 churches, 2,980 communicants, and 5,184 souls. The whole number of communicants in the 3 provinces is 12,947, and of souls 19,688. Although the church is so small, it is engaged in very extensive operations. The first enterprise which deserves to be mentioned is that of education. There are 4 church boarding schools in the American province (at Nazareth, Bethlehem, and Litiz, Penn., and Salem, N. C.), at which more than 600 pupils are annually educated; 15 in the British province, educating about 400 pupils every year; and 25 in the continental province, with about 1,050 pupils. Nearly all the scholars come from beyond the pale of the church. At Bethlehem, Penn., there is a college, and in connection with it a theological seminary. Similar institutions belong to the continental province. The next enterprise is that of domestic missions. These, in the United States, were commenced very recently among the German immigrants. There are 17 missionaries in the field, and 88 stations. On the continent of Europe the enterprise is far more extensive, and peculiarly interesting. It is called the work of the *Diaspora*, from the original Greek of 1 Peter i. 1, and has for its object the evangelization of the state churches, without proselyting their members. Hence societies within these churches are formed and regulated by the missionaries, who hold meetings for prayer and exhortation, and visit from house to house, but never administer the sacraments. There are 120 missionaries, male and female, engaged in this enterprise. It extends over Saxony, Prussia, and other German countries, Switzerland, parts of France, Denmark, Norway, Sweden, and the Russian empire. In the Russian provinces of Livonia and Esthonia the cause prospers very much, there being 265 chapels, and more than 62,000 members. The whole number of Diaspora members, as they are called, on the continent, is about 80,000. But the great work which chiefly engages the energies of the church, and in which all the provinces unite, is that of foreign missions. It was commenced in 1732, when Herrnhut constituted the only Moravian church, numbering about 600 souls. Since then 2,487 missionaries, male and female, not counting the native assistants, have labored in this field. Unsuccessful missions were commenced in Lapland, among the Samoyeds, in Algeria, Ceylon, China, Persia, the East Indies, the Caucasus, Guiana, Guinea, among the Calmucks, in Abyssinia and Tranquebar. At the present time the church has missions in Greenland, Lab-

rador, North America (among the Indians), on the Mosquito coast, in the islands of St. Thomas, St. Croix, St. Juan, Jamaica, Antigua, St. Kitts, Barbados, and Tobago, in Surinam, South Africa, Thibet, and Australia. There are 812 missionaries in the field, not counting the native assistants; 74 regular stations, not counting the out stations; and 74,538 converts under religious instruction, of whom 58,582 are in church fellowship, including baptized children, and the rest candidates for admission.—For further information in reference to the Moravians, consult "The Moravian Manual" (Philadelphia, 1859).

MORAYSHIRE. See ELGIN.

MORAZAN, FRANCISCO, a Central American statesman and general, and the last president of the republic of Central America, born in Honduras in 1799, shot in Costa Rica, Sept. 15, 1842. His father was of Corsican extraction, although born in Porto Rico, and his mother was a lady of Honduras. He was early distinguished for impetuosity, decision, perseverance, frankness, and manly bearing. In 1824 he had risen to be secretary general of Honduras, and soon after was elected chief or governor of the state, in which position he distinguished himself both as a statesman and as a military commander. In several contests he led the liberal forces of his own and the adjacent states with unvarying success, against the reactionary party, which had resorted to armed revolt, and finally in 1829 drove them from the city of Guatemala, for which act the national congress decreed him the title of saviour of the republic. He declined the proffered post of president, and contented himself with the position of commander-in-chief of the forces, in which capacity, and in virtue of special powers delegated to him by the congress, he expelled the archbishop of Guatemala, together with the active members of the various monastic orders, suppressed the convents, abolished tithes, and directed the other property and revenues of the church to purposes of education and public charities. He now devoted himself to schemes of public improvement and education, in which, however, he was arrested in 1832, by the invasion of the republic from Mexico by a large force under Arce, the expelled president, who was seconded by various local outbreaks of his partisans. These disturbances were promptly suppressed by Morazan, who soon after, at the almost unanimous solicitation of the country, accepted the presidency. In 1836 the cholera first made its appearance, with extraordinary fatality in all parts of the country. The ignorant population, but more particularly the Indians, became much alarmed and excited, and the opportunity was seized by the clerical party to proclaim that the pestilence was due to the poisoning of the waters by the whites, liberals, and foreigners. The consequence was a general outbreak of the lower orders of the people and the Indians, who made head under the lead of Rafael Carrera. At first Morazan was able to check all these hostile demonstrations; but they rapidly became general, and in 1840 he

was compelled to fly from the country. He sought refuge in Chili, whence in 1842 he went with some followers to Costa Rica, where he was received with open arms, and raised to the governorship of the state by acclamation. Regarding himself as lawful president of the republic, he at once began to organize an army with a view to the reestablishment of the old federation; but the plan was not popular with the people of Costa Rica, and a revulsion ensued which was turned to good account by his enemies. Their plan was concerted with such secrecy that Morazan and his handful of adherents were surprised, and, after a brilliant struggle, compelled to surrender. Morazan was tried by a drum-head court martial and shot, declaring in his testament, which he was allowed but one hour to prepare, that he died "on the anniversary of the independence of his country, whose integrity he had sought to maintain, leaving no enemies, and forgiving his assassins."

MORBIHAN, a maritime department of France, in the old province of Brittany, bordering on the bay of Biscay; area, 2,626 sq. m.; pop. in 1856, 478,982. Its name is derived from a gulf formed on its shore by the Atlantic, called in the local dialect Morbihan, or small sea. The coast is indented by numerous bays and harbors. The northern districts are hilly, but the southern are mainly composed of extensive and fertile plains. The principal river is the Vilaine. The sardine fishery gives employment to more than 3,000 men. The principal minerals are iron, tin, lead, slate, and salt. There are manufactures of linen, woollens, &c. Ship building is extensively carried on in the 25 seaports of the department. The inhabitants of Morbihan are Bretons, and speak a dialect somewhat similar to that of the Cornish peasants in England. Capital, Vannes.

MORDAUNT, CHARLES. See **PETERBOROUGH, EARL OF.**

MORE, HANNAH, an English authoress, born in Stapleton, Gloucestershire, Feb. 2, 1745, died in Clifton, Sept. 7, 1833. She was the daughter of a village schoolmaster, and was educated at a seminary kept by her sisters in Bristol, in the direction of which she afterward became associated. At the age of 16 she composed a pastoral drama entitled "The Search after Happiness," which was not published however until 1778. While on a visit to London she obtained an introduction to the famous literary circle of which Johnson, Burke, Garrick, and Sir Joshua Reynolds were among the principal members. Garrick and his wife were warmly attached to her, and frequently invited her to their house. In 1774 appeared her tragedy of "The Inflexible Captive," founded on the story of Regulus, and in 1775 two legendary poems, "Sir Edred of the Bower" and "The Bleeding Rock." The tragedy of "Percy," which Garrick brought out in 1777, gave her a profit of £750, and, though marked by some of the faults of inexperience, betrayed considerable dramatic powers. "The Fatal False-

hood," played soon afterward, was less successful. About this time religious impressions induced Miss More to cease writing for the stage, and her subsequent works, with the exception of a few poems, of which the "Bas Bleu," a satire on the blue stocking club, is the best known, were generally in a more serious vein. A volume of "Sacred Dramas" (1782), "Florio," a satirical tale (1786), a "Poem on the Slave Trade" (1788), "Thoughts on the Manners of the Great" (1788), and "Religion of the Fashionable World" (1791) were among her next productions. With a view of opposing the infidel and seditious principles then somewhat in vogue, she began at Bath in 1795 a monthly periodical called the "Cheap Repository," consisting of short moral tales, among which was the "Shepherd of Salisbury Plain," written by herself. The work attained an enormous circulation. Miss More having removed to Cheddart, she founded there a number of schools, and soon extended her charitable efforts for the education of the poor into all the surrounding country. After the appearance of her "Strictures on the Modern System of Female Education" (1799), she was invited to draw up a plan of instruction for the princess Charlotte of Wales, which was published in 1805 under the title of "Hints toward forming the Character of a Young Princess." "Cœlebs in Search of a Wife," her most popular work, appeared in 1809, and went through 10 editions in one year. It was followed by "Practical Piety" (1811), "Christian Morals" (1812), an "Essay on the Character and Writings of St. Paul" (1815), and "Modern Sketches" (1819). In 1828 she removed from Barleywood in Gloucestershire, where she had lived for several years with her sisters, to Clifton. She had accumulated by her writings about £30,000, one third of which she bequeathed for charitable purposes. The last edition of her works is in 11 vols. 16mo. (London, 1853).—See "Memoirs of the Life and Correspondence of Mrs. Hannah More," by William Roberts (4 vols. 8vo., London, 1834; 2 vols. 12mo., New York, 1836). The "Correspondence of Hannah More with Zachary Macaulay" (father of Lord Macaulay) was published in London in 1860.

MORE, HENRY, an English mystical divine and philosopher, born in Grantham, Lincolnshire, Oct. 12, 1614, died Sept. 1, 1687. The son of a strict Puritan, his school days at Eton were occupied by severe studies and immature speculations on the doctrine of predestination. In 1631 he removed to Christ's college, Cambridge, where he says he immersed himself over head and ears in the study of philosophy, promising himself a most wonderful happiness in it. Abandoning the Aristotelian logicians for Platonic and mystic writers, he read with delight Ficino, Plotinus, Trismegistus, and especially the *Theologia Germanica* wrongly attributed to Tauler. He took the degree of bachelor in 1635 and of master in 1639, became a fellow of his college, and passed the remainder

of his life in retirement and meditation, declining many offers of church preferment. He was private tutor to several persons of note; the rectory of Ingoldsby was resigned by him in 1642; he declined the mastership of his college in 1654, and his friend Cudworth was consequently appointed to it; and he became a prebendary of Gloucester in 1675 only in the interest of his friend Dr. Fowler. His friends once attempted to decoy him into a bishopric, but he learned their purpose while they were taking him to kiss the king's hand on occasion of his appointment, and he refused to proceed. In 1640 he published a tedious philosophical poem, entitled "Psychozoia, or the Life of the Soul." At the request of Lady Conway, a Quakeress, he wrote the *Conjectura Cabalistica*, the *Philosophia Teutonice Censura*, and other works; and she bequeathed to him a legacy of £400, which he devoted to charity. The first of these treatises was an attempt to interpret the book of Genesis into 3 distinct meanings, the literal, philosophical, and mystical or divinely moral. He wrote 4 letters to Descartes (1648-'9), which were answered by that philosopher, in which he expressed his admiration of the Cartesian system as "a fine, neat, subtle thing," but discovered defects in it, and aimed to maintain its general compatibility with the cabalistic doctrine, and its inferiority to his own principle of a divine sense. In 1656 appeared his *Enthusiasmus Triumphatus*, a discourse on the nature, causes, kinds, and cure of enthusiasm, which illustrates at once his shrewdness and his mysticism, and proves that his fancied illumination and extravagant conceits rarely prostrated his judgment. Among his other publications are *Enchiridium Metaphysicum*, displaying an intimate and extensive acquaintance with metaphysics; the "Mystery of Godliness," which enjoyed a high degree of popularity; the "Mystery of Iniquity;" a "Discourse on the Immortality of the Soul;" and a treatise entitled "Medela Mundi, or Cure of the World," which he did not live to finish. He held the opinion that the Hebrew revelation had been transmitted to Pythagoras during his travels in the East, and had been inherited from him by the Platonists, whose principles therefore were the true divine philosophy. He regarded the cabalistic speculations, also, as a corrupted offshoot from the same source. All of his writings indicate eminent erudition and acuteness. He was personally esteemed for uncommon benevolence, purity, and piety, and he was after Cudworth the ablest as well as the most amiable of the English Platonic divines of the 17th century. His principal philosophical writings appeared in English (2d ed., 1662; 4th ed., 1712), and a complete edition of his works was published in Latin (1679). His life was written by the Rev. Richard Ward (London, 1710).

MORE, SIR THOMAS, an English statesman and philosopher, born in London in 1480, executed July 6, 1535. His father was one of the justices of the court of king's bench, and was

by descent entitled to use armorial bearings, the distinctive privilege of those who then began to be called gentry. He was educated in Latin under Nicholas Hart, an eminent schoolmaster in Threadneedle street, and, according to the custom of that age for young gentlemen to spend part of their boyhood in the house of a nobleman or high ecclesiastical dignitary to profit by the conversation of experienced men and to learn the manners of the world, was placed in his 15th year in the family of Cardinal Morton, archbishop of Canterbury. There he gave brilliant proofs of natural wit, and the aged cardinal often predicted that "whosoever shall live to see it, this child will prove a marvellous rare man." In 1497 he went to Oxford as a student of Canterbury college, which afterward became Christchurch, where he was prominent as a partisan of Greek studies, against the more aged, powerful, and larger body of the university, which regarded this innovation in education with distrust. The opposing factions were styled Greeks and Trojans. He studied Greek under Grocyn, and his enthusiasm for it was increased by Erasmus, who resided at Oxford in 1497 and 1498, and formed a life-long intimacy with More. At the university, or soon after leaving it, he composed the greater part of his English verses, which sparkle with witty conceits. He also wrote Latin epigrams (Basel, 1520), which contain proofs that he always regarded government as dependent on the consent of the people. Having completed the curriculum at Oxford, he passed to the study of law successively at New Inn and at Lincoln's Inn, London, at the same time delivering lectures on jurisprudence at Furnival's Inn, and on Augustine's *De Civitate Dei*, or the divine government of the moral world, at St. Laurence's church. To the latter lectures "all the chief learned of the city" are stated to have resorted. He meditated taking holy orders, associated with the Carthusian monks of the Charterhouse, and manifested a predilection for monastic life, some of the severest austerities of which he inflicted upon himself; but he soon relinquished the project, and resolved on marriage. Of the 3 daughters of Mr. Colt, a gentleman of Essex, the second seemed to him the fairest; but when he considered the slight and consequent grief to the eldest sister if the younger were preferred to her in marriage, he then "of a certain pity framed his fancy" to the former, and soon after married her. Called to the bar, he quickly rose to professional eminence, his practice amounting in 1509 to £400 a year, about equal to an income of £5,000 at the present time. Mackintosh calls him the first person in English history distinguished for the faculty of public speaking, and remarkable for the successful employment of it against a lavish grant of money to the crown. He was employed in nearly every important case brought before the courts, was appointed to the office of judge of the sheriff's court for London and Middlesex, was elected a Burgess of

the parliament under Henry VII., and his eloquence both at the bar and in parliament was in eminent instances successful against the claims of the crown. His brilliant and effective opposition to a royal grant, causing Henry VII. to declare that "a beardless boy had disappointed all his purpose," drew a fine and imprisonment upon his father; and he himself had resolved to leave the country at the time of that monarch's death. There is little information concerning the style of his oratory. Erasmus refers to his fertile invention, untiring attention, simplicity, promptitude, and an acuteness so preëminent that he often perplexed the greatest theologians in their own province. In his prose writings, but a very small part of his vocabulary has been superannuated; but the structure of his sentences is according to the genius of the Latin rather than the English language, and differs widely from that which has since prevailed. His fragmentary "History of Richard III." (1641) is the first example of classical English prose, and abounds in skilfully constructed speeches after the manner of ancient histories. The work by which he is chiefly known as an author is his *Utopia*, published in Latin (Louvain, 1516), and soon translated into English, French, Dutch, and Italian. It is an account of an imaginary commonwealth in the island of Utopia, feigned to have been discovered by a companion of Amerigo Vespucci, from whom More learns the tale. In this perfect society, all are contented with the necessities of life, all engage in useful labor for 6 hours a day, and indolence, avarice, and want are unknown. With impracticable theories, the work expresses wide and tolerant opinions in advance of the age, and is pervaded by a sense of justice and humanity and by censures on the vices of power that are remarkable in a courtier of Henry VIII. Thus, one of the oldest laws of the Utopians is stated to be that no man should be punished for his religion, "it being a fundamental opinion among them that a man cannot make himself believe any thing he pleases." How far the various doctrines and projects contained in the *Utopia* were regarded by him with approbation, or were merely the paradoxes of a playful mind, cannot be determined. His public life had already begun. In 1514 and 1515 he was sent on two embassies to the Netherlands with reference to commercial intercourse. In 1516 he became a privy councillor and a favorite of the king, with whom he advised, jested, and discussed divinity, astronomy, and other sciences. In his leisure he corresponded with Erasmus and other men of letters of the highest eminence. In 1521 he was knighted and made treasurer of the exchequer, and at various times he was employed in France to manage the intrigues of Wolsey with Francis I. When parliament assembled in 1523, he was chosen speaker of the house of commons, and displayed his tact and quiet firmness when the house by its silence refused a heavy grant which Cardinal Wolsey had ap-

peared in state to demand. In 1525 he was appointed chancellor of the duchy of Lancaster; in 1527 he accompanied Wolsey on his magnificent embassy to France; and about this time he proved his attachment to the old form of religion by several learned, witty, and bitter pamphlets against the reformers. He succeeded to the lord chancellorship in 1529, after the fall of Wolsey, and in this position evaded the demand of the king for an opinion concerning his divorce from Queen Catharine. Froude, the last historian of this epoch, cites several cases to prove that in his official efforts for the suppression of heretics he not merely zealously executed a cruel law, but that he disregarded some of his obligations as judge. "The philosopher of the Utopia," he says, "the friend of Erasmus, whose life was of blameless beauty, whose genius was cultivated to the highest attainable perfection, was to prove to the world that the spirit of persecution is no peculiar attribute of the pedant, the bigot, or the fanatic, but may coexist with the fairest graces of the human character." The charges against him were partially denied in his "Apology," written in 1533. He constantly refused to lend his authority to the king's project of divorce and second marriage; and after holding the great seal for 2½ years he determined no longer to countenance by his official position measures which he intensely disapproved and deplored, and obtained permission to resign. In his house at Chelsea he lived in retirement, making ready for evil times. Implicated in the alleged imposture of the nun of Kent, whom he believed to be inspired, he was yet in the investigation treated leniently. When at length in 1534 he was required to swear allegiance to the act of succession for securing the throne to the offspring of Anne Boleyn, he refused, and was committed to the tower for misprision of treason, where he remained more than a year, with permission to receive his relatives and correspond with his friends. A deputation then waited on him to urge his acknowledgment of the royal supremacy, but he declined to answer. The council still hesitated, and interrogated him again and again in subsequent interviews; but finally (July 1, 1535) he was brought to the bar of the high commission charged with traitorously imagining and attempting to deprive the king of his title as supreme head of the church. He was condemned, and returned to the tower. On the morning of his execution he dressed in his most elaborate costume, preserved the amenity and composure of his character to the last, and, as the fatal stroke was about to fall, stopped for a moment's delay while he moved aside his beard, murmuring: "Pity that should be cast on that has not committed treason." "Which strange words," says Froude, "the strangest perhaps ever uttered at such a time, the most famous through Europe for eloquence and wisdom closed for ever."—The best English translation of the *Utopia* is by Bishop Barrington. A collection of More's Latin works was pub-

lished at Louvain in 1556, and of his English works at London in 1557. There are biographies by his son-in-law Roper (1626), Hoddesden (1652), his great-grandson Thomas More (1726), and Sir James Mackintosh in the "Cabinet Cyclopædia" (1831).

MOREA. See **PELOPONNESUS**.

MOREAU, JEAN VICTOR, a French general, born in Morlaix, Aug. 11, 1768, died at Laun, Bohemia, Sept. 2, 1813. He was destined for the profession of his father, who was an attorney, studied law at Rennes, and in 1787 was made provost of the school. He supported the parliament in their opposition to the crown; but perceiving that they were struggling for mere selfish purposes, he exerted his influence against them, and became the leader of the revolutionary party at Rennes. In 1792, at the head of a battalion of volunteers, he joined the army of the north, and distinguished himself on many occasions by courage, self-possession, and military skill. He was rapidly promoted, being made a brigadier-general in 1793, and general of division in 1794. Placed in command of the right wing of the army under Pichegru, he had an important share in the conquest of Holland, the whole credit of which however was given to his superior. In the campaign of 1796, while Bonaparte was accomplishing wonders in northern Italy, and Jourdan invading Germany through the valley of the Main, Moreau, at the head of the army of the Rhine, crossed the river at Strasbourg, marched toward the Black forest, drove back the Austrian troops, defeated the archduke Charles at Neresheim, Aug. 10, and penetrated to the centre of Bavaria; but hearing of the defeat which Jourdan had experienced at Würzburg, and being aware that the archduke with all the Austrian forces in Germany was falling back upon him, he thought prudent to retreat. He accomplished this in a masterly manner in the face of two powerful armies, whom he never suffered to molest him, and even attacked with success on several occasions; so that on arriving in Alsace after an orderly march of 26 days, his own force was unimpaired, and he had moreover 18 guns taken from the enemy, 2 standards, and nearly 7,000 prisoners. In the following year he recrossed the Rhine, took the fortress of Kehl, and was preparing to proceed, when he was stopped by news of the preliminaries of Leoben. He was suspected on account of his friendship to the traitor Pichegru, and for 18 months remained out of service. The directorial government recalled him in the day of danger. Sent to northern Italy under the incapable Scherer, who left him in command of the French troops when every thing seemed to be lost, he was defeated at Cassano, April 28, 1799, and performed a retreat from the banks of the Adda first to Turin, and then to Genoa, which, though less famous, is perhaps more admirable than that of 1796. He now manoeuvred to protect the return of Macdonald from central Italy; but this general having been defeated on the banks of

the Trebia, both were superseded by Joubert, under whom Moreau consented to serve. Joubert being killed at Novi, the task of saving the remnant of the French army again devolved upon Moreau, whose energy and prudence were equal to the emergency. He had meanwhile been appointed commander of the army on the Rhine. Passing through Paris, he became acquainted with Bonaparte, and assisted him on the 18th Brumaire by watching over the two reluctant directors who were kept prisoners in the Luxembourg palace. While Bonaparte was executing the brilliant campaign which ended with the victory of Marengo, Moreau, who had crossed the Rhine, April 25, 1800, had several successful contests with the Austrians, drove Gen. Kray across the Danube, won the decisive battle of Hochstätt, advanced as far as Munich, and on July 15 signed the armistice of Parsdorff. Austria showing a disinclination to a definite arrangement, and being encouraged by England to keep up the war, a winter campaign was required to bring her to terms. Moreau, with an army of 100,000 men, received orders to cross the Inn and march to Vienna. On Dec. 8 he met the Austrians under the archduke John at Hohenlinden, where he won a brilliant victory. He followed it up with decision and activity, crossed the Inn, the Salza, and the Traun, defeated the archduke Charles at Lambach, occupied Linz on the Danube and Steyer on the Enns, and was within two days' march of Vienna when the emperor consented to the terms proposed by the first consul, and signed the treaty of Lunéville, Feb. 9, 1801. On his return to Paris, Moreau married; and yielding to the influence of his wife and mother-in-law, who persuaded him that he was not treated as he deserved to be, he gave free expression to his discontent, and was privy to, if not deeply concerned in, the conspiracy of Georges Cadoudal and Pichegru in 1804. For this he was sentenced by a court martial to two years' imprisonment, which Bonaparte commuted to exile. Moreau came to the United States, and engaged in agricultural pursuits. At the end of 9 years Alexander I. of Russia invited him to return to Europe, and on his arrival gave him a flattering welcome. He was induced by the czar to devise, in conjunction with another French soldier who had also deserted the cause of Napoleon, a plan for the invasion of France. He became a bosom companion of Alexander; he was near him at the battle of Dresden, Aug. 27, 1813, and was advising upon a certain manoeuvre on a hill near Räcknitz, when a cannon ball from Napoleon's guard broke both his legs. He was carried to an adjoining village in Bohemia, and died 5 days later. Prince Repnin caused a monument to be erected upon the hill where he was wounded, and his remains were interred in St. Petersburg. A monument was dedicated to him in Paris in 1819. The *Vis politique, militaire et privée du général Moreau* was published by A. de Beauchamp (8vo., Paris, 1814); but the best account of him is found in

Thiers' *Histoire de la révolution Française*, and *Histoire du consulat et de l'empire*.

MOREAU DE JONNÈS, ALEXANDRE, a French statistician, born near Rennes, March 19, 1778. He enlisted in 1792 as a volunteer in the revolutionary army, served in many of the campaigns of the republic and the empire, and was made a prisoner in 1809. After recovering his liberty, he rejoined the army, but left it after the restoration. From that time he devoted himself to the study of statistics, and in 1817 he was appointed editor of the *Statistique générale de la France*, published under the auspices of the government. He has been for the last 44 years corresponding member of the academy of sciences, and in 1847 he became an honorary member of the academy of moral and political sciences. After the *coup d'état* of Dec. 2, 1851, he withdrew from public service on his retiring pension. He is the author of many works on statistics, which enjoy a high reputation.

MOREHOUSE, a N. parish of La., bordering on Arkansas, bounded W. by the Washita, and drained by Bartholomew and Boeuf rivers; area, 950 sq. m.; pop. in 1858, 5,426, of whom 2,698 were slaves. It has an undulating surface subject to be submerged, with a fertile soil. The productions in 1850 were 119,285 bushels of corn, 25,925 of sweet potatoes, and 8,303 bales of cotton. Capital, Bastrop.

MOREL, CHRISTOPHE ÉDOUARD, a French teacher of deaf mutes, born in Bouxwiller, department of Bas-Rhin, Dec. 5, 1805, died in Bordeaux, Feb. 28, 1857. His mother was the sister of the first baron de Gerando, under whose superintendence he was educated. He was graduated at the college of Besançon, and in 1824 connected himself with the royal institution for deaf mutes at Paris. In 1826 De Gerando, then at the head of the administrative board of that institution, confided to Morel the task of preparing "circulars" (which were really large volumes) giving information respecting the instruction of deaf mutes and the management of institutions for their training. They were published by the Paris institution, the first in 1827, and the fourth and last in 1836. In 1844 Morel undertook, on his own responsibility, the publication of the quarterly *Annales des sourd-muets et des aveugles*, which was continued for 8 years. In 1845 the *classe de perfectionnement* of the Paris institution, answering to the high class in American institutions, which had been endowed by Dr. Itard, was organized, and M. Morel at once placed in charge of it. In 1847 he took an active part in the establishment of a society for the aid of blind workmen, and in 1849 assisted in organizing the central society of education and aid for deaf mutes in France. In 1850 he was made director of the institution for deaf mutes at Bordeaux; but his health soon failed, and he passed more than 6 years previous to his death in severe suffering.

MORELLA, COUNT DE. See CABRERA, RAMON.

MORELOS, JOSÉ MARIA, a Mexican revolutionist, born in the latter part of the 18th cen-

tury, shot in the city of Mexico, Dec. 22, 1813. He was curate of Nocupetaro in Valladolid, and in Oct. 1810, joined the insurgent chief Hidalgo, who was then in arms against the Spaniards, and who gave him a commission to act as captain-general of the provinces on the S. W. coast. He set out with 5 negroes to conquer Acapulco, which was garrisoned by a large body of troops. On his march he was joined by about 1,000 men, chiefly negro slaves, with whom under cover of night he surprised and signally defeated the Spaniards, Jan. 25, 1811. The rest of the year he spent in successful partisan warfare, during which he was joined by Galeano, Matamoros, Nicolas Bravo, afterward president, and several other men of distinguished talent. His army, which was mostly composed of negroes, at length acquired by experience sufficient discipline to be openly led against the royal forces, and Morelos accordingly marched upon the capital. He encountered the Spanish army at Cuautla Amilpas, 65 m. from Mexico, Feb. 12, 1812, and defeated it after a hard-fought battle, in which the royalists lost 500 men. A second army was sent against him, and for several weeks he was besieged in Cuautla, which he defended with great spirit, and from which he skilfully withdrew his troops May 2, in the face of a greatly superior force. Subsequently he won several victories over the Spanish troops, captured Tehuacan, Orizaba, and Oajaca, and at length compelled Acapulco to surrender, Aug. 31, 1813. In December of the same year he marched against Valladolid, but was defeated there by Iturbide with great loss. From this time he suffered a succession of defeats, till on Nov. 5, 1815, he was taken prisoner after a gallant resistance against an overwhelming force, and was carried to Mexico, tried, and executed.

MORETO, AGUSTIN, a Spanish dramatist, born at the end of the 16th or beginning of the 17th century, died in Toledo, Oct. 28, 1669. He was descended from an ancient Valencian family, and was prominent as a writer for the stage until the last 12 years of his life, which he passed in religious retirement as rector of the hospital *del refugio* of Toledo. He was a friend of Lope de Vega and Calderon and an imitator of their productions. "Of those that divided the favor of the public with their great master," says Mr. Ticknor, "none stood so near to him as Agustín Moreto." His works comprise a small number of religious and heroic plays, and some serious dramas, as *El valiente justiciero*, and *La fuerza de la sangre*. His most popular comedy, *Inden con el desen* ("Disdain met with Disdain"), is reckoned among the 4 classic productions of the Spanish drama, and was adapted for the French stage by Molière (*Princesse d'Élide*), for the Italian by Carlo Gozzi (*Principessa filosofo, o il contraveleno*), and for the German by Joseph Schreyvogel (West), under the title of *Donna Diana*. The most complete edition of his comedies was issued between 1677 and 1681, though not including them all.

MORETTO, IL. See BORVIGNO.

MORFIT, CAMPBELL, an American chemist, born in Herculaneum, Mo., in 1820. He studied at Columbian college, Washington, D. C., but was prevented by delicate health from completing the course, and devoted himself to the study of chemistry in the laboratory of Prof. James O. Booth of Philadelphia. He then entered a laboratory for the manufacture of commercial chemicals, and became eventually the proprietor of it, obtaining for his products medals from the Franklin and American institutes. In 1848 he became co-editor with Prof. Booth of the "Encyclopædia of Chemistry." Of his many contributions to journals, the principal are papers upon guano, salts, sugars, the analysis of coals, gum mezquite, and glycerine. He also wrote a report upon gun metal to the U. S. ordnance department. For the investigations to which this latter refers he established a laboratory at the Pikesville arsenal, Md., upon his own plan. During this time he originated the chemical department of the Maryland institute, but declined to take charge of it. The honorary degree of M.D. has been conferred upon him by the university of Maryland and the New York medical college. He filled the chair of analytical and applied chemistry in the university of Maryland from 1854 to 1858; which post he resigned to remove to New York, where he now resides. He is chiefly distinguished in technical and analytical chemistry; and his principal works are: "Applied Chemistry in the Manufacture of Soap and Candles" (Philadelphia, 1847); "Chemical and Pharmaceutic Manipulations" (1848); "The Arts of Tanning and Currying," from the French, with additions (1852); "Perfumery, its Manufacture and Use" (1855); and a report of the "Progress of the Chemical Arts," prepared with Prof. Booth for the Smithsonian institution, by which it was published in 1851.

MORGAGNI, GIOVANNI BATTISTA, an Italian anatomist, born in Forlì, Feb. 25, 1682, died in Padua, Dec. 6, 1771. After taking his degree of M.D. at Bologna, he repaired to Venice and ultimately to Padua, where in 1712 he became professor of the theory of physic; and in 1715, as successor of Molinetti, he was appointed to the principal anatomical chair in the same institution, which he continued to occupy till his death. He was the first to show the importance of anatomy as being the basis of all other medical studies, and is regarded as the founder of pathological anatomy. His most celebrated works are: *Adversaria Anatomica* (4to., Padua, 1719), afterward enlarged and published under the title of *Adversaria Omnia* (6 vols., Padua, 1741); and particularly his *De Sedibus et Causis Morborum per Anatomen Indagatis* (2 vols. fol., 1761; last ed., 6 vols., Leipsic, 1827), which has been translated into various European languages.

MORGAN, the name of counties in 9 of the United States. I. A N. co. of Va., separated from Md. by the Potomac, and drained by Cacapon river and Sleepy creek; area, 850 sq. m.;

pop. in 1850, 8,557, of whom 128 were slaves. The surface is mountainous, and the soil light and unproductive except in the valleys. There are large deposits of iron and coal. Berkley Springs in this county is one of the oldest watering places in the United States. The productions in 1850 were 46,247 bushels of Indian corn, 40,584 of wheat, and 16,388 of oats. There were 7 grist and saw mills, 11 churches, and 645 pupils attending public schools. The Baltimore and Ohio railroad and the Chesapeake and Ohio canal follow the course of the Potomac through the county. Value of real estate in 1856, \$727,152, showing an increase over 1850 of 6 per cent. Capital, Bath. II. A central co. of Ga., bounded E. by Appalachee and Oconee rivers, and drained by their branches; area, 272 sq. m.; pop. in 1859, 9,679, of whom 6,779 were slaves. The surface is undulating, and the soil is fertile and based on limestone. Small quantities of gold have been found, and there are large quarries of granite. The productions in 1850 were 411,857 bushels of Indian corn, 86,990 of oats, 66,299 of sweet potatoes, and 11,541 bales of cotton. There were 12 grist mills, 6 saw mills, 3 tanneries, 19 churches, and 517 pupils attending public schools. The Georgia railroad passes through Madison, the capital. III. A N. co. of Ala., bounded N. by the Tennessee river; area, 720 sq. m.; pop. in 1850, 10,125, of whom 8,437 were slaves. The surface is mountainous, and the soil generally fertile. The productions in 1850 were 4,767 bales of cotton, 464,440 bushels of Indian corn, and 56,846 of oats. There were 17 churches, and 172 pupils attending public schools. The Memphis and Charleston railroad passes through the N. part of the county. Capital, Somerville. IV. A N. E. co. of Tenn., drained by the head streams of Emory's river; area, 640 sq. m.; pop. in 1850, 8,480, of whom 101 were slaves. The surface is diversified by mountains, covered with large forests. There are extensive beds of coal. The productions in 1850 were 103,522 bushels of Indian corn, 18,874 of oats, and 81,184 lbs. of butter. Capital, Morgan Court House. V. An E. co. of Ky., intersected by Licking river; area, 806 sq. m.; pop. in 1850, 7,620, of whom 187 were slaves. The surface is hilly, and the soil is rich in the valleys. Timber is abundant, and iron, coal, alum, copperas, and oil springs are found. The productions in 1850 were 267,275 bushels of Indian corn, 28,705 of oats, and 16,988 lbs. of wool. There were 6 grist mills, 14 churches, and 558 pupils attending public schools. Capital, West Liberty. VI. A S. E. co. of O., intersected by Muskingum river; area, 860 sq. m.; pop. in 1850, 28,585. It has an uneven surface and a rich soil, based on limestone. Large quantities of salt are procured in this county. In 1850 the productions were 266,286 bushels of wheat, 570,896 of Indian corn, 162,818 of oats, and 421,144 lbs. of tobacco. There were 11 grist mills, 24 saw mills, 72 churches, 2 newspaper offices, and 5,905 pupils attending public schools. Capital, McCon-

nellsville. VII. A central co. of Ind., drained by the W. fork of White river and its branches; area, 453 sq. m.; pop. in 1850, 14,576. The surface in the S. is uneven, in other parts level, and the soil is fertile. The productions in 1850 were 1,213,153 bushels of Indian corn, 98,850 of wheat, 92,831 of oats, 44,595 lbs. of wool, and 2,688 tons of hay. There were 54 churches, and 2,090 pupils attending public schools. Capital, Martinsville. VIII. A W. co. of Ill., bounded W. by the Illinois river, and drained by several creeks which afford water power; area, 650 sq. m.; pop. in 1855, 17,735. The surface consists chiefly of rich level prairies diversified by small groves. The soil is a deep black loam, and coal is abundant. The productions in 1850 were 2,693,021 bushels of Indian corn, 91,453 of wheat, 154,805 of oats, 893,180 lbs. of butter, 54,648 of wool, and 9,723 tons of hay. There were 13 grist mills, 6 saw mills, 88 churches, and 1,500 pupils attending public schools. The great western railroad passes through Jacksonville, the capital. IX. A central co. of Mo., bounded S. in part by Osage river, and drained by some of its tributaries; area, 648 sq. m.; pop. in 1856, 5,767, of whom 581 were slaves. The surface is diversified, and in some places well wooded. The soil is generally fertile. Lead, coal, and limestone are found. The productions in 1850 were 234,015 bushels of Indian corn, 11,933 of wheat, 54,272 of oats, and 60,103 lbs. of butter. There were 10 churches, and 280 pupils attending public schools. Capital, Versailles.

MORGAN, DANIEL, an American revolutionary general, born in New Jersey in 1736, died in Winchester, Va., July 6, 1802. He was of humble parentage, and in early life removed to Frederic, now Clarke co., Va. In 1755 he joined the expedition of Braddock as a teamster, and for some real or fancied indignity to a British officer received 500 lashes. He was accustomed, however, in after life jestingly to maintain that the drummer had miscounted the number and still owed him one. He also received a painful wound which disfigured his countenance for life. Returning to Frederic, he pursued the rough life of a backwoods farmer until the outbreak of the revolution, when, in command of a company of riflemen, all of whom like himself were expert marksmen, he started for Boston, reaching the American camp, after a march of 600 miles, in 8 weeks. In the latter part of 1775 he accompanied the expedition of Arnold to Quebec, and participated in the attack on that city on Dec. 31. Although successful in that part of the field where he held command, he was compelled by the fall of Montgomery and the defeat of his division to surrender. During his captivity he declined the offer of a colonelcy in the British army, and soon after his release, toward the close of 1776, was appointed colonel of a rifle regiment. During Washington's retreat through New Jersey in 1776 and the campaign in the same state in 1777, he rendered valuable services, and in the summer of

the latter year joined Gates, then in command of the northern army. In the battle of Bemis heights, which precipitated the surrender of Burgoyne, Morgan's riflemen took a distinguished part; yet their leader was unnoticed by Gates in his official account of the occurrence, and an attempt was even made to induce him to join the Conway cabal against Washington, which he scornfully repelled. Continuing in active service in the north until the summer of 1780, Morgan was then made brigadier-general and transferred to the southern army, where he reached subsequent to the defeat of Gates at Camden. Under Gates's successor, Greene, he acted with his accustomed energy, gaining a decisive victory over Tarleton at the Cowpens Jan. 17, 1781, for which he received a gold medal from congress, and following it up by a series of well conceived manœuvres which seriously embarrassed Cornwallis. But before the close of the campaign he was compelled by repeated and severe attacks of rheumatism to retire to his home in Virginia. In 1794 he acted in quelling the whiskey insurrection in Pennsylvania, and was a member of congress from 1795 to 1799. The latter part of his life was passed in much physical suffering.

MORGAN, SIR HENRY, a buccaneer of the 17th century, was the son of a farmer in Wales. For many years he maintained his position among the West India islands as chief of a band of pirates, composed of adventurers from all nations of Europe. From his stronghold, one of which was the island of St. Catharina, he made many successful descents upon the Spanish settlements in his vicinity, and at sea captured many rich prizes. The most daring of these expeditions was in 1666, in which with about 1,200 followers he took and plundered both Porto Bello and Panama, and by which he amassed a large fortune. He afterward settled at Jamaica, of which island he was appointed lieutenant-governor, and knighted, by Charles II.

MORGAN, SYDNEY (OWENSON), lady, an Irish authoress, born about 1780, died in London, April 13, 1859. From her father, a doctor, and a man of considerable literary attainments, she inherited a taste for literature. In 1797 appeared her first publication, a volume of poems, followed by a collection of Irish tales, once very popular, and "The Lays of an Irish Harp," of which a second edition was printed in 1807. Her next literary ventures were the tales, "St. Clair" and "The Novice of St. Ignace," succeeded in 1801 by "The Wild Irish Girl," a work which chimed in very largely with the taste of the time, and introduced her to the most fashionable literary circles of England. So popular did the novel become, that upward of 7 editions of it were printed in 4 years. In 1807 appeared her "Patriotic Sketches of Ireland;" in 1808, "Woman, or Ida Athens;" and in 1809, "The Missionary." In 1811 she was married to Sir T. Charles Morgan, with whom she subsequently travelled over various parts of Europe, residing for considerable

periods in France and Italy. Among the results of her travels was a review of the social state of France (4to., London, 1817), which engendered controversy respecting the accuracy of her judgments. A similar work on Italy, composed from a journal kept during a residence in that country in 1819-'20 (2 vols. 8vo., London, 1821), was also the cause of much controversy, in which, as in the case of her work on France, by her wit and sprightliness she frequently got the better of her adversaries. As recently as 1851 she published a reply to some comments by Cardinal Wiseman on statements made in this book respecting the chair of St. Peter deposited in the cathedral at Rome. Among her remaining works were her novels, "O'Donnell," "Florence Macarthy," and "The O'Briens and the O'Flahertys;" "The Life and Times of Salvator Rosa" (1824), "Woman and her Master" (1840), "Passages from my Autobiography" (1858), &c. As a conversationist Lady Morgan was one of the most brilliant of her time, and by her tact, ready sympathy, and unvarying cheerfulness acquired and long maintained a position in the most distinguished society of Britain. Without remarkable personal attractions, she knew society thoroughly, and even in old age exercised a singular fascination over those admitted to her circle. She was the survivor of that cluster of literary women who flourished in England in the early part of the present century, and passed the latter years of her life at her residence in London, in the enjoyment of a pension of £300 conferred upon her during the ministry of Earl Grey. In 1860 appeared a memoir of her, entitled "Lady Morgan, her Career, Literary and Personal," by William J. Fitzpatrick.—SIR THOMAS CHARLES, an English physician and author, husband of the preceding, born about 1783, died Aug. 28, 1843. He was educated at Eton and Cambridge, and in 1809 took his degree of M.D. Soon after his marriage with Miss Owen he took up his residence in Ireland, having a place under government as a commissioner of the Irish fisheries. He gradually relinquished his profession for the pursuit of literature, and was an industrious contributor to the "New Monthly Magazine" and other periodicals. He is the author of "Sketches of the Philosophy of Life" (1818), and "Sketches of the Philosophy of Morals" (1822), and published in conjunction with his wife a collection of essays and miscellanies under the title of "The Book without a Name" (1841). He also furnished some appendices to Lady Morgan's work on France.

MORGAN, WILLIAM. See ANTI-MASONRY.

MORGANA. See FATA MORGANA.

MORGANATIO MARRIAGE (Ang. Sax. *norgan gifu*, Germ. *Morgengabe*, morning gift or lowry), the term for a marriage concluded between a man of superior and a woman of inferior rank, in which it is stipulated that the latter and her children shall be entitled neither to the rank nor to the possessions of the husband, the lowry (morning gift) being in lieu of all other

privileges. Marriages of this kind are not infrequent in the princely houses of Germany, and one of the most noted was that of King Frederic William III. of Prussia with the countess Auguste von Harrach, who thereupon received the title of princess of Liegnitz.

MORGARTEN, a hill in Switzerland, about 2 m. W. of Rothenthurm, on the margin of the lake of Egeri, on the confines of the canton of Zug, memorable as the scene of the battle of Nov. 15, 1815, in which a small body of Swiss mountaineers from Schwytz, Uri, and Unterwalden, ill armed and undisciplined, totally vanquished an Austrian army of 20,000 under the archduke Leopold. This was the first victory achieved by the Swiss in their struggle for freedom. A chapel stands at the foot of the hill, in which service is performed annually on the anniversary of the battle.

MORGHEN, RAFFAELLO SANZIO, an Italian engraver, born in Florence, June 19, 1758, died there, April 8, 1833. He was instructed by his father, an engraver, in the principles of his art, and at 20 years of age executed a series of plates representing masks from the carnival of Naples. He was then placed in the school of Volpato in Rome, and in 1781 married the only daughter of his master, whom he assisted on several important works; and in 1787 he produced his fine engraving of Guido's "Aurora" in the Rospigliosi palace at Rome. In 1790 he visited Naples, whence, notwithstanding many flattering inducements to remain held out to him by the court, he removed in 1798 to Florence, and opened a public school of engraving, receiving at the same time a pension of 400 scudi from the grand duke. His first important work in Florence was the print of Raphael's *Madonna della seggiola*, and in 1795 he commenced the *Madonna del saccio* of Andrea del Sarto, and the "Transfiguration" of Raphael, the latter his most elaborate work. He had partially finished the plate from a drawing by A. del Era, when a comparison of the copy with the original showed so many faults in the former that he was induced to abandon the work and commence another plate from a drawing by Tofanelli, which was completed in 1812 and dedicated to the emperor Napoleon. Notwithstanding the labor bestowed upon it, this is considered a less meritorious work of art than his print of the "Last Supper" after Leonardo da Vinci, the early impressions of which are among the most precious productions of the graver. According to his pupil Palmerini, Morghen executed 78 portraits, many of which were of living personages beside the great poets and painters of Italy, 47 biblical and religious pieces, 44 historical and mythological pieces, 24 views and landscapes, and 18 vignettes and crests. The Palmerini collection of prints by him is probably the most perfect in existence.

MORHOF, DANIEL GEORGE, a German scholar, born in Wismar, Feb. 6, 1689, died in Lübeck, June 30, 1691. He was professor of poetry at Rostock and Kiel, and afterward taught also his-

tory and superintended the library in the last named university. He was a man of great learning for his time, and his principal work, *Polyhistor* (Lübeck, 1688), opened a new era in the study of literary history in Germany, and was for a long time a standard work.

MORIAH, MOUNT. See JERUSALEM.

MORIER, JAMES, an English author, born about 1780, died in Brighton in March, 1849. He was descended from a family from French Switzerland, who had settled in England. He studied the oriental languages, spent about 6 years in Persia as secretary of legation and minister plenipotentiary, and published "Travels in Persia, Armenia, and Asia Minor to Constantinople" (London, 1812); "A Second Journey through Persia, Armenia, and Asia Minor" (1818); and a series of novels, the most interesting of which is "The Adventures of Hajji Baba" (5 vols., 1824-'8). Among his other works are "Zohrab, or the Hostage" (1832), "Ayesha, the Maid of Kars" (1834), and "The Mirza" (1841), all illustrations of Persian life.—His brother **DAVID** was also in diplomatic employment, and was minister to Switzerland (1832-'47). In his treatise, "What has Religion to do with Politics?" (London, 1848; German, Basel, 1851), he endeavored to prove that true statesmanship must be essentially based upon religion.

MORILLO, PABLO, count of Carthagena and marquis de la Puerta, a Spanish general, born in Fuente in 1777, died in Madrid in 1838. He first served in the navy and afterward in the army against Napoleon, and rose to the rank of general. In 1815 he was placed at the head of the Spanish forces in South America, where he became noted for his cruel treatment of the revolted colonists. He was eventually defeated by Bolivar and compelled to sign the truce of Truxillo (Nov. 25, 1820), after which he returned to Spain. In his subsequent course he alternately sided with the absolutist and constitutional parties without enjoying the confidence of either. In 1823 he took for a brief period the part of the royalists against the cortes of Seville, but afterward submitted to the regency and surrendered Galicia to the French. After the restoration of absolute monarchy he was expelled from the country and his estates were confiscated. In 1832 he was permitted to return and appointed governor of Galicia. For some time previous to his death he acted as commander of the forces against Don Carlos. He published his *Mémoires* in Paris in 1826.

MORIN, ARTHUR JULES, a French engineer, born in Paris, Oct. 19, 1795. He was educated at the polytechnic school of Paris and at the military academy of Metz, where he officiated for some time as professor of mechanics. Subsequently he became professor of practical mechanics in the *conservatoire des arts et métiers* in Paris, and has now (1860) for some years been at the head of that institution. He holds the rank of general in the army, and is a member of the academy of sciences and of the board of artillery. In 1855 he acted as presi-

dent of the imperial commission of the great French exposition. He has published many works on mechanical subjects.

MORIN, FRÉDÉRIC, a French author, born in Lyons, June 11, 1823. He officiated for several years as professor of philosophy at Mâcon and Nancy, from whence he was dismissed after the *coup d'état* of Dec. 1851, and appointed to an inferior position at the lyceum of Bourges; he resigned it because he would not swear allegiance to the imperial government, and has since resided in Paris. In 1857 he was defeated as the opposition candidate for the department of Rhone in the legislative assembly. He belongs to that party of Roman Catholic politicians who advocate a liberal alliance with all other religious denominations for the defence of the principles of the first French revolution. He is the author of *Saint François d'Assises et les Portugais* (1853); *De la Genèse et des principes métaphysiques de la science moderne* (1856); and *Dictionnaire de philosophie et de théologie scolastiques* (2 vols., 1857-'8), which last forms part of Abbé Migne's collection.

MORISCO (Sp., Moorish), a term applied to the Moors of Granada after their forcible conversion to Christianity in 1500.

MORLAKS, or **MORLACHIANS** (Slav. *Primorci*, adjoining the sea), a rude people of uncertain origin, inhabiting the mountainous coast land of Dalmatia, the Croatian Military Frontier, and the Hungarian Littorale, on the Adriatic. They speak a south-Slavic dialect, are mostly Roman Catholics, make skilful mariners, and form a large proportion of the sailors in the Austrian navy. The strait which separates the islands of Veglia, Arbe, and Pago from the coast is generally called the strait of Morlana.

MORLAND, GEORGE, an English painter, born in London, June 26, 1763, died there in 1806. His father, an artist of moderate abilities, perceiving in him early symptoms of genius, employed it to his own advantage, and between the ages of 14 and 21 young Morland was engaged in making pictures and drawings for sale. When 21 he left his father's house and pursued his art alone, reaching the full maturity of his powers about 1790, after which period he gave himself up to intemperance and profligacy. During the last few years of his life he was seldom sober, and painted only to supply his actual necessities; and many of his later works were executed in sponging houses, in one of which he died. His subjects were generally selected from low life, and notwithstanding he had received no academical instruction and was ignorant of anatomy, he acquired an astonishing skill in painting domestic animals, the pig being his favorite. He was also very successful in delineating the more common species of English landscape, consisting of fields and hedges, ponds of water and clay banks. His execution deteriorated greatly toward the close of his life, but his pictures were nevertheless in such demand that a regular manufactory of imitations of them was established by his brother Henry.

At the present day well authenticated pictures by Morland bring large prices.

MORMONS, or LATTER DAY SAINTS, the followers of a religion founded by Joseph Smith, who was born at Sharon, Windsor co., Vt., Dec. 23, 1805, and killed at Carthage, Ill., June 27, 1844. At the age of 10 years he removed with his parents to Palmyra, Wayne co., N. Y. From the testimony of their neighbors in Palmyra, the reputation of the Smiths was bad. They avoided honest labor, and occupied themselves chiefly in digging for hidden treasures and in similar visionary pursuits. They were intemperate and untruthful, and were commonly suspected of sheep stealing and other offences. Upward of 60 of the most respectable citizens of Wayne co. testified in 1833, under oath, that the Smith family were of immoral, false, and fraudulent character, and that Joseph was the worst of them. These statements are not, in general, contradicted by the Mormons. His most distinguished disciple, Brigham Young, says: "The doctrine he teaches is all I know about the matter; bring any thing against that if you can. As to any thing else, I do not care if he acts like a devil; he has brought forth a doctrine that will save us, if we will abide by it. He may get drunk every day of his life, sleep with his neighbor's wife every night, run horses and gamble; I do not care any thing about that, for I never embrace any man in my faith." The Mormon writers state that Smith was very poorly educated. He could read with difficulty, wrote an imperfect hand, and had a very limited understanding of the elementary rules of arithmetic. The revelations, proclamations, letters, and other documents put forth by him in the subsequent part of his career, were generally written by others. According to his own account, Smith at about the age of 15 years began to have visions. On the night of Sept. 21, 1823, the angel Moroni appeared to him three times, giving him much instruction, and informing him that God had a work for him to do; and that a record written upon gold plates, and giving an account of the ancient inhabitants of America and the dealings of God with them, was deposited in a particular place in the earth (a hill in Manchester, Ontario co., N. Y.), and, with the record, two transparent stones in silver bows like spectacles, which were anciently called the Urim and Thummim, on looking through which the golden plates would become intelligible. On Sept. 22, 1827, the angel of the Lord placed in Smith's hands the plates and the Urim and Thummim. The plates were nearly 8 inches long by 7 wide, and a little thinner than ordinary tin, and were bound together by 3 rings running through the whole. Altogether they were about 6 inches thick, and were neatly engraved on each side with hieroglyphics in a language called the reformed Egyptian, not then known on the earth. From these plates Smith, sitting behind a blanket hung across the room to keep the sacred rec-

ords from profane eyes, read off, with the aid of the stone spectacles, the "Book of Mormon," or Golden Bible as he sometimes called it, to Oliver Cowdery, who wrote it down as Smith read it. It was printed in 1830, in a volume of several hundred pages. Appended to it was a statement signed by Oliver Cowdery, David Whitmer, and Martin Harris, who had become professed believers in Smith's supernatural pretensions, and are called by the Mormons "the three witnesses." They said: "We declare with words of soberness that an angel of God came down from heaven, and he brought and laid before our eyes that we beheld and saw the plates and the engravings thereon." Several years afterward, however, all three of these witnesses quarrelled with Smith, renounced Mormonism, and avowed the falsity of their testimony. In a Mormon publication, "Elder's Journal" (1837), Smith himself wrote thus of Harris: "There are negroes who have white skins as well as black ones; Granny Parish and others, who acted as lackeys, such as Martin Harris. But they are so far beneath my contempt, that to notice any of them would be too great a sacrifice for a gentleman to make." Immediately on the appearance of the "Book of Mormon" many of Smith's neighbors testified that he had repeatedly made contradictory statements about the plates and the Golden Bible. Peter Ingersoll, one of his intimate friends, declared under oath: "Smith told me the whole affair was a hoax, that he had no such book, and did not believe that there was such a book in existence; but, said he, as I have got the damned fools fixed, I shall carry out the fun." The "Book of Mormon" is a collection of 16 distinct books professing to be written at different periods by successive prophets. Its style is an exceedingly clumsy and verbose imitation of that of the common English translation of the Bible, portions of which, to the number in all of 300 passages, are incorporated without acknowledgment, and are frequently cited by Mormons as specimens of the book. A multitude of names are introduced, some Hebrew and biblical, others Greek and Latin, and the rest imitations of the former. The first book professes to be the work of Nephi, a Jew, the son of Lehi, who dwelt at Jerusalem in the days of King Zedekiah, about 600 B. C. In obedience to the command of the Lord, who appeared to him in a dream, he went into the wilderness of Arabia and dwelt there a long time with his family. At length, still under divine instruction, Lehi and his family set out in search of a promised land, and after travelling "nearly eastward" for 8 years, "through a wilderness," they reached the ocean. Here they built a ship, and, guided by a compass, sailed to America. The Book of Mormon itself gives no indication of the part of the continent on which they landed, but later Mormon interpretations or revelations declare it to have been the coast of Chili. Those who arrived in America were Lehi and his wife, his 4 sons,

Laman, Lemuel, Sam, and Nephi, and their 4 wives, 2 "sons of Ishmael" and their 2 wives, and Zoram, a servant, and his wife; in all, 8 adult men with as many wives. Beside these, there were 2 infant sons of Lehi born during the journey through the wilderness, Jacob and Joseph. In America they found "beasts in the forest of every kind, both the cow, and the ox, and the ass, and the horse, and the goat." Soon after his arrival in America Lehi died, and dissensions speedily ensued between Nephi and his elder brothers Laman and Lemuel; and, separating from them, Nephi moved into the wilderness accompanied by Sam and Zoram and their families, the boys Jacob and Joseph, and such of the women and children as took his side. Laman and Lemuel and the "sons of Ishmael" and their families, as a punishment for rebelling against Nephi, whom the Lord had appointed to be their ruler, were cursed by the Lord, and they and all their posterity condemned to have dark skins and to "become an idle people, full of mischief and subtlety, which did seek in the wilderness for beasts of prey." This was the origin of the American Indians, who are consequently believed by the Mormons to be of Jewish race. Nephi and his 4 companions multiplied and prospered in their new settlement to such a degree that within 80 years after their departure from Jerusalem, that is, within 22 years after their arrival in America, they had become so numerous and rich that Nephi says: "And I did teach my people to build buildings; and to work in all manner of wood, and of iron, and of copper, and of brass, and of steel, and of gold, and of silver, and of precious ores, which were in great abundance. And I, Nephi, did build a temple; and I did construct it after the manner of the temple of Solomon, save it were not built of so many precious things; for they were not to be found upon the land; wherefore it could not be built like unto Solomon's temple. But the manner of the construction was like unto the temple of Solomon; and the workmanship thereof was exceeding fine. . . . And it came to pass that I, Nephi, did consecrate Jacob and Joseph, that they should be priests and teachers over the land of my people. And it came to pass that we lived after the manner of happiness. And thirty years had passed away from the time we left Jerusalem." Nephi died about 50 years after his arrival in America, and his people continued to be called Nephites and to be governed by kings bearing the name of Nephi for many generations. The record of their history was continued on golden plates by Jacob the brother of Nephi, Enos the son of Jacob, Jarom the son of Enos, Omni the son of Jarom, and finally by Mormon, whose name is given to a single book, as well as to the whole volume, and who, "many hundred years after the coming of Christ," transmitted to his son Moroni the plates containing the writings of the authors already mentioned, together with those of Mosiah,

Zeniff, Alma, Helaman, Nephi the Second, and Nephi the Third. These books consist almost wholly of a narrative of transactions in North and South America, chiefly of wars between the Nephites and the Lamanites or red men, and of revolutions in the land of Zarahemla, which was near the isthmus of Darien, where there was an exceeding great city. At length, in the days of Nephi the Second, a terrible earthquake announced the crucifixion of Christ at Jerusalem; and 8 days afterward the Lord himself descended out of heaven into the chief city of the Nephites in sight of all the people, to whom he exhibited his wounded side and the prints of the nails in his hands and feet. He remained among them 40 days, instructing them in Christianity and instituting Christian churches. The Christians of America, unlike their brethren in the rest of the world, immediately adopted the Christian era for their chronological computations; and according to the record, in the 4 following centuries the wars between them and the heathen Lamanites continued to rage, with great destruction of the Christians, whose populous and civilized cities, which were very numerous throughout North America, were gradually captured and destroyed. In the year 384 the Christians made their final stand at the hill Cumorah, in western New York, where in a great battle 230,000 of them were slain. Moroni, one of the survivors, after wandering as a fugitive till A. D. 420, sealed up the golden plates on which all these things were written, and hid them in the hill where they were found by Joseph Smith. One of the books in the collection, the book of Ether, gives an account of an earlier settlement of America than that of Lehi, by a colony from the tower of Babel soon after the deluge, which was led by Jared, and in time became a great nation which was destroyed for its sins before the arrival of the colony from Jerusalem. The book of Alma, which professes to have been written several centuries before Christ, contains the following passage: "For do we not read, that God is the same yesterday, to-day, and for ever, and that in him there is neither variableness nor shadow of changing?" These expressions, which the author of Alma quotes as written and read in his day, were also written in Greek by Paul and James in their epistles in the first century after Christ. At a still earlier period Nephi, anticipating Shakespeare, wrote of "the cold and silent grave whence no traveller returns."—The religious teachings of the "Book of Mormon" relate in great part to doctrinal questions that were rife in the villages of western New York about 1830. Calvinism, Universalism, Methodism, Millenarianism, Roman Catholicism, and other modern forms of belief are discussed. Infant baptism is warmly recommended, and polygamy is repeatedly denounced, as for example: "For behold, thus saith the Lord, this people begin to wax in iniquity; they understand not the Scriptures; for they seek to excuse themselves in committing whoredoms because of the things which were written . . ."

cerning David and Solomon his son. Behold, David and Solomon truly had many wives and concubines, which thing was abominable before me, saith the Lord. Wherefore, thus saith the Lord, I have led this people forth out of the land of Jerusalem, by the power of mine arm, that I might raise up unto me a righteous branch from the fruit of the loins of Joseph. Wherefore I, the Lord God, will not suffer that this people shall do like unto them of old. Wherefore, my brethren, hear me and hearken to the word of the Lord; for there shall not any man among you have save it be one wife; and concubines he shall have none; for I, the Lord, delighteth in the chastity of women." Free masonry, which about 1830 was a popular subject of discussion in western New York, figures extensively in the "Book of Mormon," which abounds in anti-masonic denunciations of secret societies, though Smith and all the leading Mormons subsequently became free masons, and organized their ecclesiastical hierarchy in imitation of the masonic system of degrees.—According to the opponents of Mormonism, from investigations made soon after the appearance of the "Book of Mormon," the fact is fully established that the real author of the work was Solomon Spalding, who was born in Ashford, Conn., in 1761, was graduated at Dartmouth college, and was afterward ordained. After preaching for 8 or 4 years, he relinquished the ministry, and engaged in mercantile business at Cherry Valley, N. Y., whence in 1809 he removed to Conneaut, Ohio. From Conneaut in 1812 he removed to Pittsburg, and hence in 1814 to Amity, Penn., where he died in 1816. He had an inveterate taste for literary pursuits, and wrote several novels, which he was in the habit of reading to his friends in manuscript, as they were so worthless that he could find no publisher for them, while his poverty prevented him from issuing them at his own expense. During his residence in Ohio in 1810-'11-'12 he wrote a romance to account for the peopling of America by deriving the Indians from the Hebrews, in accordance with an absurd notion then prevalent in some parts of the country that the American Indians were descended from the lost tribes of Israel. As early as 1813 this work was announced in the newspapers as forthcoming, and as containing a translation of the "Book of Mormon." Spalding entitled his book "Manuscript Found," and intended to publish with it by way of preface or advertisement a fictitious account of its discovery in a cave in Ohio. His widow, in a statement published by her in the "Boston Journal," May 18, 1839, declares that in 1812 he placed his manuscript in a printing office at Pittsburg, with which Sidney Rigdon was connected. Rigdon, she says, copied the manuscript; and his possession of a copy was known to all in the printing office, and was often mentioned by himself. Subsequently the original manuscript was returned to the author, who soon after died. His widow preserved it till

after the publication of the "Book of Mormon," when she sent it to Conneaut, where a public meeting, composed in part of persons who remembered Spalding's work, had requested her to send the manuscript that it might be publicly compared with the "Book of Mormon." She says in conclusion: "I am sure that nothing would grieve my husband more, were he living, than the use which has been made of his work. The air of antiquity which was thrown about the composition doubtless suggested the idea of converting it to the purposes of delusion. Thus, a historical romance, with the addition of a few pious expressions, and extracts from the Sacred Scriptures, has been construed into a new Bible, and palmed off upon a company of poor deluded fanatics as divine." Sidney Rigdon was born in St. Clair township, Alleghany co., Penn., Feb. 19, 1798. Soon after getting possession of a copy of Spalding's manuscript, he quitted the printing office and became a preacher of doctrines peculiar to himself, and very similar to those afterward incorporated into the "Book of Mormon." He had a small body of converts to his notions when about 1829 he became associated with Joseph Smith, who was then endeavoring to gain believers to his tale of the golden plates and stone spectacles. It is asserted that through Rigdon's agency Smith became possessed of a copy of Spalding's manuscript, which he read from behind the blanket to his amanuensis Oliver Cowdery, with such additions as suited the views and purposes of Rigdon and himself. Immediately on its publication, the "Book of Mormon" was claimed not only by Spalding's widow but by many of his friends as his long lost work. John Spalding, a brother of Solomon, says in a deposition: "I made him (Solomon Spalding) a visit in about 3 years after (1813), and found that he had failed, and was considerably involved in debt. He then told me he had been writing a book, which he intended to have printed, the avails of which he thought would enable him to pay all his debts. The book was entitled 'Manuscript Found,' of which he read to me many passages. It was a historical romance of the first settlers of America, endeavoring to show that the American Indians are the descendants of the Jews or the lost tribes. It gave a detailed account of their journey from Jerusalem, by land and sea, till they arrived in America under the command of Nephi and Lehi. They afterward had quarrels and contentions, and separated into two distinct nations, one of which he denominated Nephites and the other Lamanites. Cruel and bloody wars ensued, in which great multitudes were slain. They buried their dead in large heaps, which caused the mounds so common in this country. Their arts, sciences, and civilization were brought into view, in order to account for all the curious antiquities found in various parts of North and South America. I have recently read the 'Book of Mormon,' and to my great surprise I find nearly the same historical matter,

names, &c., as they were in my brother's writings. I well remember that he wrote in the old style, and commenced about every sentence with 'And it came to pass,' or 'Now it came to pass,' the same as in the 'Book of Mormon;' and according to the best of my recollection and belief, it is the same as my brother Solomon wrote, with the exception of the religious matter. By what means it has fallen into the hands of Joseph Smith, jr., I am unable to determine." Martha Spalding, the wife of John Spalding, Henry Lake, the partner in business of Solomon Spalding, and many others corroborated these statements in the fullest manner. John N. Miller of Springfield, Penn., testified in Sept. 1838, that in 1811 he was in the employ of Spalding, and lodged and boarded in his house, and frequently perused portions of the "Manuscript Found," which the author also sometimes read to him. Miller says: "I have recently examined the 'Book of Mormon,' and find in it the writings of Solomon Spalding, from beginning to end, but mixed up with Scripture and other religious matter, which I did not meet in the 'Manuscript Found.' Many of the passages in the Mormon book are *verbatim* from Spalding, and others in part. The names of Nephi, Lehi, Moroni, and in fact all the principal names are brought fresh to my recollection by the gold Bible." The printing of the "Book of Mormon" was done at the expense of Martin Harris, who had some property, and was persuaded that he could make money by the speculation. While the work was in progress, this man called upon Prof. Anthon of New York with a transcript on paper which Smith had given him of the characters on one of the golden plates. "This paper," Prof. Anthon states in a letter dated New York, Feb. 17, 1834, "was in fact a singular scroll. It consisted of all kinds of crooked characters, disposed in columns, and had evidently been prepared by some person who had before him at the time a book containing various alphabets, Greek and Hebrew letters, crosses and flourishes; Roman letters, inverted or placed sideways, were arranged and placed in perpendicular columns; and the whole ended in a rude delineation of a circle, divided into various compartments, decked with various strange marks, and evidently copied after the Mexican calendar given by Humboldt, but copied in such a way as not to betray the source whence it was derived." This letter was written to contradict a report set afloat by Smith that Prof. Anthon had pronounced the characters to be Egyptian hieroglyphics.—Smith and Rigdon seem at first to have had vague and confused ideas as to the nature and design of the church they were about to establish. They were both inclined to teach millenarianism, which at that time was beginning to attract attention in western New York; and they accordingly settled into the doctrine that the millennium was close at hand, that the Indians were to be speedily converted, and that America was to be

the final gathering place of the saints, who were to assemble at New Zion or New Jerusalem somewhere in the interior of the continent. With the "Book of Mormon" as their text and authority, they began to preach this new gospel; and Smith's family and a few of his associates, together with some of Rigdon's previous followers, were soon numerous enough to constitute the Mormon church, as it was styled by the people around them, or the church of Latter Day Saints, as they presently began to call themselves. The church was first regularly organized at Manchester, N. Y., April 6, 1830, and the first conference was held at Fayette, N. Y., in June, at which time the number of believers had increased to 80. Smith, directed as he said by revelation, in Jan. 1831, led the whole body of believers to Kirtland, Ohio, which was to be the seat of the New Jerusalem. Here converts were rapidly made, and soon desiring a wider field for the growth of the church, Smith and Rigdon travelled westward looking for a suitable location, which was found in Independence, Jackson co., Mo., where in August Smith dedicated a site for the temple to be erected by the saints, and named the place New Jerusalem. On their return to Kirtland, where they proposed to remain for 5 years "and make money," Smith and Rigdon established a mill and a store, and set up a bank without a charter, of which Smith appointed himself president, and made Rigdon cashier. The neighboring country was flooded with notes of very doubtful value; and in consequence of this and other business transactions in which Smith and Rigdon were accused of fraudulent dealing a mob on the night of March 22, 1832, dragged the two prophets from their beds, and tarred and feathered them. About a year afterward a government for the church was instituted, consisting of 8 presidents, Smith, Rigdon, and Frederick Williams, who together were styled the first presidency, a revelation from the Lord having declared that the sins of Rigdon and Williams were forgiven, "and that they were henceforth to be accounted as equal with Joseph Smith, jr., in holding the keys of his last kingdom." About this time Brigham Young became a convert to Mormonism. He was born at Whitingham, Vt. June 1, 1801, and was the son of a farmer who had been a soldier of the revolution. He arrived at Kirtland toward the close of 1832 and was soon ordained an elder, and began to preach. His talent and shrewdness speedily made him prominent, and in Feb. 1835, when a further step was taken in the organization of a hierarchy by the institution of the quorum of the 12 apostles, he was ordained one of the 12 and sent out with the other apostles to preach the new doctrines. His field of labor was the eastern states, and he was signally successful in making converts. In 1836 a large and costly temple, which had been for 8 years in process of building, was consecrated at Kirtland; and in 1837 Orson Hyde and Heber C. Kimball, the latter of whom had become a convert in

1832, were sent as missionaries to England. In Jan. 1838, the bank at Kirtland having failed, Smith and Rigdon, to avoid arrest for fraud, fled in the night, hotly pursued by their creditors, and took refuge in Missouri. In that state, meanwhile, large numbers of Mormons had collected, and had become involved in quarrels with the people, by whom they were charged with plundering and burning habitations, and with secret assassinations; and after various conflicts with mobs, who drove them successively from Jackson co. and from Clay co., they settled in Caldwell co., at the town of Far West, where Smith and Rigdon joined them. The conflicts with the Missourians still continued, and many outrages were committed and several persons killed on both sides. In the midst of their external troubles, internal dissensions broke out among the Mormons. Several of their leading men apostatized and accused Smith of gross crimes and frauds. On Oct. 24, 1838, Thomas B. March, the president of the 12 apostles, and Orson Hyde, also one of the apostles, made before a justice of the peace in Ray co., Mo., an affidavit in which March said, corroborated by Hyde: "They have among them a company, consisting of all that are considered true Mormons, called the Danites, who have taken an oath to support the heads of the church in all things that they say or do, whether right or wrong. . . . The plan of said Smith, the prophet, is to take this state; and he professes to his people to intend taking the United States, and ultimately the whole world. This is the belief of the church, and my own opinion of the prophet's plan and intentions. The prophet inculcates the notion, and it is believed by every true Mormon, that Smith's prophecies are superior to the law of the land. I have heard the prophet say that he would yet tread down his enemies and walk over their dead bodies; that if he was not let alone he would be a second Mahomet to this generation, and that he would make it one gore of blood from the Rocky mountains to the Atlantic ocean." The defiant and menacing tone of the Mormon leaders contributed much to the excitement against them. Rigdon, in a sermon preached at Far West, July 4, 1838, said: "We take God and all the holy angels to witness this day, that we warn all men in the name of Jesus Christ to come on us no more for ever. The man, or the set of men, who attempts it, does it at the expense of their lives. And that mob that comes on us to disturb us, it shall be between them and us a war of extermination, for we will follow them till the last drop of their blood is spilled, or else they will have to exterminate us. For we will carry the seat of war to their own houses, and their own families, and one party or the other shall be utterly destroyed." Toward the close of 1838 the conflict between the Mormons and the Missourians assumed the character and proportions of civil war. The Mormons armed themselves, and assembling in large bodies fortified their towns and defied the officers of the

law. The militia of the state was called out by the governor, and Rigdon and Smith were arrested, charged with treason, murder, and felony. The forces of the state being overwhelming in number, the Mormons capitulated and agreed to quit Missouri, and to the number of several thousands crossed the Mississippi into Illinois. They were soon after joined by Smith, who broke out of the gaol where he had been confined awaiting trial. Rigdon had previously been liberated by a writ of habeas corpus. The following extract from the message of the governor of Missouri in 1840 states the character of the transactions which resulted in the expulsion of the Mormons: "These people had violated the laws of the land by open and avowed resistance to them; they had undertaken, without the aid of the civil authority, to redress their real or fancied grievances; they had instituted among themselves a government of their own, independent of and in opposition to the government of this state; they had, at an inclement season of the year, driven the inhabitants of an entire county from their homes, ravaged their crops, and destroyed their dwellings. Under these circumstances it became the imperious duty of the executive to interpose and exercise the powers with which he was invested, to protect the lives and property of our citizens, to restore order and tranquillity to the country, and maintain the supremacy of our laws." The Mormons were kindly received in Illinois, and Dr. Isaac Galland, who owned a large tract of land at Commerce, Carthage co., Ill., gave Smith a considerable portion of it in order to enhance the value of the rest by the settlement of the Mormons there. Smith accordingly received a revelation commanding the saints to establish themselves at Commerce, and build a city to be called Nauvoo on the land presented to him, which he divided into house lots and sold to his followers at high prices. By this transaction, and by other equally successful speculations, the prophet in a few years amassed a fortune estimated at upward of \$1,000,000. Nauvoo soon grew to be a city of several thousand inhabitants, the saints being summoned by a new revelation to assemble there from all quarters of the world, and to build a temple for the Lord, and a hotel in which Smith and his family should "have place from generation to generation, for ever and ever." The legislature of Illinois granted a charter for the city of Nauvoo, conferring upon it extraordinary privileges, which enabled Smith, Rigdon, and the other leaders to exercise almost unlimited civil power. They were authorized by charter to organize a military body, which was accordingly formed under the name of the Nauvoo legion, and comprised nearly all the Mormons capable of bearing arms. Smith was commander of this force with the rank of lieutenant-general. Beside this office, he held those of mayor of the city and first president of the church. By a revelation given April 6, 1830, he had been appointed "seer, translator, prophet, apostle of

Jesus Christ, and elder of the church;" and the Lord had said of him: "The church shall give heed to all his words and commandments which he shall give unto you; for his word shall ye receive as if from my own mouth, in all patience and faith." This revelation gave the prophet absolute authority over his followers, making him the mouthpiece of God himself. The civil and military offices which he conferred upon himself at Nauvoo and the legion at his command gave him supreme power within the city, whose charter had been purposely so framed that the state authorities were almost excluded from jurisdiction within its limits. On April 6, 1841, the foundation of the temple was laid at Nauvoo, by Lieut. Gen. Smith, who appeared at the head of the legion, surrounded by a numerous military staff; and the saints being commanded by revelation not only to contribute to its erection, but to labor personally upon the work every tenth day, its walls rapidly arose.—In 1838 Smith had persuaded a number of women to cohabit with him, calling them his spiritual wives, although he had a lawful wife to whom he had been married in 1827. His wife became jealous of these rivals, and to pacify her Smith received, July 12, 1843, a revelation authorizing polygamy. This fact being whispered at Nauvoo, much scandal was created in consequence. The imputation was strenuously denied in public, and in 1845 the heads of the church deemed it prudent to put forth a formal denial of the charge in the following words: "Inasmuch as this church of Christ has been reproached with the crimes of fornication and polygamy, we declare that we believe that one man should have but one wife, and one woman but one husband; except in case of death, when either is at liberty to marry again." It was not till 1852 that they admitted the truth, and boldly avowed and defended polygamy on the authority of the revelation of 1843. Meantime Smith in 1843 and 1844 made advances to so many women in Nauvoo, soliciting them to become his spiritual wives, that great uproar was created by the declarations of those whose virtue was proof against his attempts. Among others who repelled and denounced him publicly was Mrs. Foster, wife of Dr. Foster. Her husband, together with William Law and others who had been similarly outraged, renounced Mormonism, and commenced at Nauvoo the publication of a newspaper, the "Expositor," to expose Smith. In the first number they printed the affidavits of 16 women to the effect that Joseph Smith, Sidney Rigdon, and others had endeavored to convert them to the spiritual wife doctrine, and to seduce them under the plea of having had special permission from heaven. This publication created great excitement, and on May 6, 1844, Smith and a party of his followers attacked the "Expositor" office and razed it to the ground, destroying the presses and other contents of the building. Foster and

Law fled and took refuge in Carthage, the county seat, where they obtained warrants against Joseph Smith, his brother Hyrum Smith, and 16 others. The warrant was served upon Smith, but he refused to obey, and the constable who served it was driven from Nauvoo. The county authorities called out the militia to enforce the law; the Mormons armed themselves and a civil war seemed impending, when the governor of the state persuaded the two Smiths to surrender and take their trial. They were committed to the gaol at Carthage, and a guard stationed for their protection. On the evening of June 27 a mob, composed chiefly of Missourians, attacked the gaol, overpowered the guard, and fired upon the prisoners with rifles through a window and door. Hyrum Smith was instantly shot dead. Joseph returned the fire with a revolver till his charges were exhausted, and then attempted to escape through the window, but was shot as he leaped through it and fell to the ground dead. The death of the prophet caused much temporary confusion among the saints. Sidney Rigdon aspired to succeed him as head of the church; but Brigham Young was chosen first president, and Rigdon, being contumacious, was cut off from the communion of the faithful, cursed, and solemnly delivered to the devil "to be buffeted in the flesh for a thousand years." In 1845 the charter of Nauvoo was repealed by the legislature of Illinois, and the Mormons made preparations to remove to the Rocky mountains. Early in the following year they gathered in considerable numbers at Council Bluffs in Iowa. Those who remained in Nauvoo became again involved in trouble with the surrounding people, and in Sept. 1845 the city was cannonaded for 8 days and its inhabitants driven out at the point of the bayonet. In the following year pioneers crossed the plains from Council Bluffs to Salt Lake valley, Utah, where Brigham Young arrived July 24, 1847. In May, 1848, the main body of the saints set out for Utah, and arrived at the Great Salt Lake in the autumn. Salt Lake City was founded (see SALT LAKE CITY), and large tracts of land brought under cultivation. An "emigration fund" was established, and large numbers of converts brought by a well organized system from Europe, chiefly from the working classes of Great Britain, and especially from Wales. A considerable number came also from Sweden and Norway, and a smaller number from Germany, Switzerland, and France. In March 1849, a convention was held at Salt Lake City and a state organized under the name of Deseret, a word understood by the Mormons to signify "the land of the honey bee." A legislature was elected and a constitution framed and sent to Washington; but congress refused to recognize the new state, and in September organized the country occupied by the Mormons into the territory of Utah, of which Brigham Young was appointed governor by President Fillmore. In the following year the federal judges of the territory were forced by threat

of violence from Brigham Young to quit Utah, and the laws of the United States were openly defied and subverted. This led to the removal of Brigham Young, and the appointment of Col. Steptoe of the U. S. army as governor. Col. Steptoe arrived in Utah in Aug. 1854, with a battalion of soldiers; but such was the state of affairs in the territory that he did not deem it prudent to assume the office of governor, and after wintering in Salt Lake City he formally resigned his post and removed with his troops to California. In a sermon preached in the tabernacle at Salt Lake City on the Sunday after Col. Steptoe's departure, Brigham Young said: "I am, and will be governor, and no power can hinder it, until the Lord Almighty says: 'Brigham, you need not be governor any longer.'" Most of the civil officers who were commissioned about the same time with Col. Steptoe arrived in Utah a few months after he had departed. They were harassed and terrified like their predecessors. In Feb. 1856, a mob of armed Mormons, instigated by sermons from the heads of the church, broke into the court room of the U. S. district judge, and at the point of the bowie knife compelled Judge Drummond to adjourn his court *sine die*. Soon afterward all the U. S. officers, with the exception of the Indian agent, were forced to flee from the territory. These and similar outrages at length determined President Buchanan to supersede Brigham Young in the office of governor, and to send to Utah a military force to protect the federal officers and to compel obedience to the laws. The Mormons on their part attempted to justify their treatment of the U. S. officials, by alleging that some of them were profligate and disreputable persons, an accusation which they attempted to sustain by scandalous statements which were probably not entirely destitute of truth. In 1857 the office of governor of Utah was conferred upon Alfred Cumming, a superintendent of Indian affairs on the upper Missouri, and that of chief justice on Judge Eckels of Indiana; and a force of 2,500 men under experienced officers was sent to protect them in the discharge of their proper functions. The Mormons were greatly excited at the approach of these troops. Young in his capacity of governor issued a proclamation denouncing the army as a mob, and forbidding it to enter the territory, and calling the people of Utah to arms to repel its advance. The army reached Utah in September, and on Oct. 5 and 6 a party of mounted Mormons attacked and destroyed several of the supply trains, and a few days later cut off 800 oxen from the rear of the army and drove them to Salt Lake City. The army, of which Col. Johnston had by this time assumed the command, was overtaken by the snows of winter before it could reach Salt Lake valley, and about the middle of November went into winter quarters on Black's Fork near Fort Bridger. On Nov. 27 Gov. Cumming issued a proclamation declaring the territory to be in a state of rebel-

lion. In the spring of 1858, however, by the intervention of Mr. Thomas L. Kane of Pennsylvania, who had gone to Utah by way of California, bearing letters from President Buchanan, a good understanding was brought about between Gov. Cumming and the Mormon leaders; and toward the end of May two commissioners, Gov. Powell of Kentucky and Major McCulloch of Texas, arrived at the camp with a proclamation from the president, offering pardon to all Mormons who would submit themselves to the federal authority. This offer of pardon was accepted by the heads of the church, and shortly afterward the troops entered Salt Lake valley, and were stationed at Camp Floyd on the western side of Lake Utah, about 40 m. from Salt Lake City, where they remained till May, 1860, when they were withdrawn from the territory.—The number of Mormons in Utah is computed by their own authorities at 80,000 or 100,000, but it is maintained by other residents of the territory that this is an exaggeration, and that the real number is about 50,000. The number in other parts of the United States is very small. In New York and its neighborhood there are about 200. The number in the old world is estimated at 100,000, chiefly in Europe, though some are found in Asia, Africa, Australia, and Polynesia.—The priesthood of the Mormon church is organized into the following quorums: the first presidency, the twelve apostles, the high council, the seventies, high priests, elders, priests, teachers, and deacons. The first presidency (in 1860) consists of Brigham Young, Heber O. Kimball, and Daniel O. Wells. They preside over and direct the affairs of the whole church. The twelve apostles constitute a travelling presiding high council. The whole hierarchy is divided into two bodies, the Melchisedek priesthood and the Aaronic priesthood. To the former, which is the highest, belong the offices of apostle, seventy, patriarch, high priest, and elder. The Aaronic priesthood includes the offices of bishop, priest, teacher, and deacon, and can be held only by "literal descendants of Aaron," who are designated as such by revelation. The Mormon church teaches that there are many gods, and that eminent saints become gods in heaven, and rise one above another in power and glory to infinity. Joseph Smith is now the god of this generation. His superior god is Jesus, whose superior god and father is Adam. Above Adam is Jehovah, and above Jehovah is Elohim. All of these gods have many wives, and they all rule over their own descendants, who are constantly increasing in number and dominion. The glory of a saint when he becomes a god depends in some degree on the number of his wives and children, and therefore polygamy is inculcated and wives are "sealed" to saints here on earth to augment their power in the heavens. The gods are in the form of men, and they are the fathers of the souls of men in this world. The ten commandments are considered the rule of life together

with a revelation given to Joseph Smith, Feb. 27, 1833, which is called "A Word of Wisdom." It teaches that it is not good to drink wine or strong drinks, excepting in the sacrament of the Lord's supper, and then it should be home-made grape wine; that it is not good to drink hot drinks, or chew or smoke tobacco; that strong drinks are for the washing of the body, and that tobacco is an herb for bruises and sick cattle; that herbs and fruits are for the food of man; that grain is for the food of man and beasts and fowls; and that flesh is not to be eaten by man excepting in times of winter, cold, and famine. This "Word of Wisdom," however, is not regarded precisely as a commandment, but as a revelation to show forth the will of God, and "suited to the condition of all saints, young and old, male and female, without distinction." Infant baptism is condemned, but the children of the saints are considered old enough at 8 years to be baptized. Baptism for the dead is practised, a living person being publicly baptized as the representative of one or more deceased persons. Washington, Franklin, and other famous men have thus been vicariously baptized into the church. There have been many dispensations of religious truth, beginning with Adam and ending with the greatest of all, that through Joseph Smith, which is to culminate in the building of the New Jerusalem in Jackson co., Mo., and the gathering together of all the saints on the continent of America. A portion of the Mormons reject polygamy, and do not approve of the political schemes of Brigham Young and the leaders of the church in Utah. Joseph Smith, the son of the prophet, is regarded by them as the true living head of the church, and under his direction they have recently established themselves at Nauvoo. Their number is inconsiderable. (For the political and social condition of the Mormons in Utah, see UTAH.)—See "The Mormons," by Charles Mackay (London, 1851); "The Mormons or Latter Day Saints in the Valley of the Great Salt Lake," by Lieut. J. W. Gunnison (Philadelphia, 1852); "Utah and the Mormons," by Benjamin G. Ferris (New York, 1856); "The Book of Doctrines and Covenants selected from the Revelations of God by Joseph Smith" (Liverpool, 1854); "A compendium of the Faith and Doctrines of the Church of Jesus Christ of Latter Day Saints," by Franklin D. Richards, one of the twelve apostles (Liverpool, 1857); "Mormonism, its Leaders and Designs," by John Hyde, jr., formerly a Mormon elder (New York, 1857).

MORNAY, PHILIPPE DE, seigneur du Plessis-Marly, frequently known under the name of Duplessis-Morny, a French soldier, statesman, and theologian, born at Buhy, Isle de France, in 1549, died in 1623. His father was a Roman Catholic, but his mother secretly brought him up as a Protestant, and after his father's death in 1560 he openly professed that religion. At an early age he travelled extensively in continental Europe. Subsequently he attached himself to

Admiral Coligni, and drew up a memorial in behalf of the Huguenots, which was presented to Charles IX., and Catharine de' Medici. After the massacre of St. Bartholomew's day, from which he had a narrow escape, he took refuge in England. In 1575 he was recalled by Henry of Navarre, afterward Henry IV., who intrusted to him the administration of the finances and some important missions to Queen Elizabeth. Being appointed general superintendent of Navarre, he stood almost alone the brunt of the religious civil war. On the alliance of his master with Henry III., he was placed in command of the town of Saumur, assigned as a place of safety to the Protestants. In 1589 he kidnapped and kept prisoner the old cardinal of Bourbon, when the leaguers had proclaimed king in opposition to his nephew Henry IV., the lawful heir to the crown. In 1592 he entered into a negotiation with Mayenne, who was willing to submit to the king. He opposed the abjuration of Henry IV., and evinced so intemperate a zeal for Calvinism as to incur the king's displeasure. Nevertheless he kept his governorship of Saumur, where, on the death of Henry IV., he proclaimed the authority of Maria de' Medici; but he quarrelled with that princess, and in 1594 was compelled to resign his office, receiving as indemnity a sum of 100,000 livres. His high character, virtue, and knowledge made him for nearly half a century the chief of the French Calvinists; and he was commonly styled by the Catholics *le pape des Huguenots*. He left various controversial works, and also his personal *Mémoires*, which were published in 1624, '51, and '52, in 4 vols. 4to., and more completely by Auguis (12 vols. 8vo., 1822-'5).

MORNY, CHARLES AUGUSTE LOUIS JOSEPH DE, count, a minister and reputed half brother of Napoleon III., born in Paris, Oct. 23, 1811. He is regarded as the son of Queen Hortense and of the count de Flahaut. He assumed the name of the count de Morny, a French nobleman resident at the Isle de France (Mauritius) who is said to have received 800,000 francs for adopting him as a son. He was educated under the care of his supposed grandmother, the accomplished Mme. de Flahaut, also known as Mme. de Souza from her second marriage with a Portuguese nobleman of that name, and placed in the institution Muron, where Edgar Ney was among his classmates. His proficiency in study was remarkable, and he was early introduced into society, where he was much noticed on account of his elegant and winning manners. It is related that on one occasion when he came to visit Talleyrand, with whom he was a favorite, that diplomatist said to a high personage who came immediately after young Morny had been drawn: "Did you meet a little fellow behind the hand of M. de Flahaut?" "Yes, prince," the staircase," was the reply. "Well," said Talleyrand, "remark what I say: that child will one day be minister." He attended one of the principal military academies of Paris during two years, and left it in 1832 with the

rank of sub-lieutenant, after which he was stationed for some time at Fontainebleau, where he is said to have turned his attention to the study of metaphysics and theology, although he does not seem to have long continued to cultivate those branches of knowledge. He served for some time in Algeria, where he was wounded, and was decorated with the order of the legion of honor for having saved the life of Gen. Trézel. Queen Hortense, on her death in 1837, bequeathed to him an annuity of 40,000 francs, and almost from that period until the present time he has been noted for his commercial and financial speculations. He made his début in the world of industry as a manufacturer of beet root sugar (1838), and has since been connected more or less successfully with most of the great enterprises which have in turn tempted the cupidity or the adroitness of French speculators. Previous to the revolution of 1848 he was for nearly 8 years a member of the chamber of deputies, and in 1849 he was elected to the legislative assembly; but up to that time his influence in political life proceeded from his occasional ability in handling financial and industrial subjects, and chiefly from his reputation as a versatile, skilful, and frequently successful speculator. The advent of Louis Napoleon to the presidency brought him into the front rank of prominence. He became the most devoted and adroit tool of his half brother, and one of his most effective assistants in the consummation of the *coup d'état* of Dec. 2, 1851. After that event he held the office of minister of the interior until Jan. 23, 1852, when he relinquished it because Fould and other of his colleagues had withdrawn from the administration on account of the confiscation of the property of the Orleans family. Subsequently he became a member of the legislative body, and since 1854 he has officiated as its president. He attended the coronation of the emperor Alexander II. as the representative of the French government, and was treated in Russia not merely as the ambassador but as the private friend of the French emperor. In St. Petersburg as in Paris he ingratiated himself, by the amenity of his manners and the liveliness of his conversation, with almost every one who came within his sphere, and gained the hand of the young and wealthy princess Trubetskoi, who had been brought up at the institution of the imperial maids of honor, and whom the empress dowager wished to place among the ladies of the reigning empress; the latter, however, declined her services on account of her being too beautiful, but sent her as a wedding present her portrait set with diamonds. The marriage was celebrated Feb. 19, 1857, at St. Petersburg, according to Greek and Catholic rites; and the count is said to have presented his bride with diamonds to the value of 2,000,000 francs. He purchased also, in the name of his wife, a seignorial estate of the Sevlosky family, about 12 miles from St. Petersburg. The present Sir Robert Peel, in one of his humorous speeches to his constituents,

describes Morny as "a spick and span man of considerable *aplomb*, and who, by the way, is one of the greatest speculators in the world."

MORO, ARRONI, also called Sir Anthony More, a Flemish painter, born in Utrecht about 1525, died in Antwerp in 1581. Early in life he gained considerable reputation as a portrait painter, and executed likenesses of the infante, the future Philip II. king of Spain, and of various members of the royal family of Portugal. In 1554 he painted the portrait of Philip's second wife, Mary of England, during whose reign he occupied the position of court painter and was probably knighted. Several of his portraits of the queen and of the English nobility are in the palace at Hampton Court. Subsequently he was in the service of Philip II. and the duke of Alva, by the latter of whom he was appointed to the lucrative office of receiver general of the revenues of West Flanders. His portraits were greatly inferior to Holbein's, to whom some of his works in England are attributed; he occasionally attempted figure pieces.

MOROCCO, or MAROCCO (called by the natives *Moghrib-el-akaa*, "the extreme West," or briefly *Moghrib*), an empire in the N. W. of Africa, between lat. 28° and 36° N., and long. 1° 20' and 11° 30' W., bounded N. by the strait of Gibraltar and the Mediterranean, E. by Algeria, S. by the Sahara, and W. by the Atlantic ocean; area estimated at 222,560 sq. m.; pop. at 6,000,000 to 8,000,000. The empire is composed of the territories of Fez, Morocco, and Taflet. Fez and Morocco lie N. W. of the Atlas mountains, the former occupying the basin of the Mulweeyah and the country N. of about lat. 32°; and Taflet is on the opposite side of the mountain range. The whole empire is divided into 30 governments, each administered by a kaid. Morocco, however, is not territorially divided in the manner usual in other countries; but the division best known in it is derived from the tribes occupying certain districts, which are very unequal in extent, and continually varying, sometimes confined to a single town, and sometimes embracing an extensive territory. Beside Morocco, the capital, the chief towns are Tangier, Tetuan, El Araish or Larash, Salé and Rabatt, Mogadore or Suira, the port of the town of Morocco, Agadir, Fez, Teza, Mequinez, Tefsa, Demnet, Terodant, Tadsî, Taflet, Tatta, and the Spanish town of Ceuta, near the W. entrance of the strait of Gibraltar. The coast line is but little indented, and there are not many good harbors; Tangier and Mogadore are the best, the rest being mere open roadsteads at the mouths of rivers. On the Mediterranean, along which Morocco extends for 230 m., the coast is bold and rocky; the most remarkable promontories are those of Ceuta, opposite Gibraltar, and Cape Spartel, a little further W. This rocky coast continues beyond the strait as far as lat. 35°, where its character changes, and it becomes low, faced with sand hills. Further S. it becomes rocky again, and the S. boundary terminates in Cape

Nun. The Atlas mountains extend through Morocco from N. E. to S. W.; their S. portion is called the Greater, and the N. the Lesser Atlas. The chain is composed of several parallel ranges, and contains the most elevated points known in N. Africa; the highest is about 18,000 feet above the sea; and Miltsin, a peak distant about 80 m. S. S. E. from the city of Morocco, is 11,500 feet high. Many of the peaks are covered with snow for the greater part of the year. Adjoining the central chain are several table lands of great extent, and at a little distance N. from it extends the maritime chain, called Er Rif, having a general height of from 2,500 to 3,500 feet. Little is known of the inferior chains which run parallel with the Atlas in the desert, in the S. E.; but they are not supposed to be of great extent. The Atlas mountains separate the rivers of Morocco which enter the Atlantic, from those which either fall into the Mediterranean or are lost in the sands of the Sahara. The rivers flowing from the N. side of the Atlas have the shorter course, but are perennial, while those running S. are dry in summer. The Maloovia or Mulweeyah, which rises in the Atlas near lat. $32^{\circ} 30'$, flows N. E., and falls into the Mediterranean after a course of 850 m. The lower part of the course of this stream forms the boundary between Morocco and Algeria, as settled by the treaty of 1845; and it is the largest river of the empire which falls into the Mediterranean. There are 7 considerable rivers flowing into the Atlantic. The Fileli, Ziz, and Ghir rise on the E. side of the Atlas and flow S. into the Sahara. N. W. of the Atlas mountains the land slopes gradually toward the sea, and the soil is fertile. The plains which lie to the S. E. of the mountains are rocky and barren, but there are groves of date palms, and the region is called Bilud-ul-Gerid, or the "country of palms." No traces of volcanic agency have been discovered in the geological formation of the country. The lower portions of the Atlas, to the height of 3,000 or 4,000 feet, consist of secondary limestone.—Along the Atlantic coast the climate is temperate, the sea breezes blowing with great regularity, and the mountains sheltering the country from the hot winds of the desert. In this region the thermometer seldom rises above 90° , and rarely falls below 40° . The year is divided into a wet and a dry season; during the former, from November to March, showers are frequent; but during the other part of the year rain seldom falls. Toward the S. there is less rain; and on the S. E. side of the mountains our knowledge of the climate is very imperfect, but extremes of heat and cold are supposed to prevail, and rain to be entirely wanting.—So far as is known, the mineral wealth of Morocco consists of iron, lead, tin, copper, antimony, and salt. Gold and silver are also found in small quantities in some places. Wheat and barley are raised in the plains, beside rice, maize, and durra; the last grain constitutes the principal food of the lower classes.

Cotton, tobacco, sesamum, hemp, saffron, and different kinds of beans and peas are grown. The fruit trees of S. Europe are very common, especially the fig and pomegranate. The plantations of olive and almond trees are very extensive; the date tree is cultivated on the S. declivity of the mountains. The sugar cane thrives under tillage. There are many wild animals, especially in the S. parts. Among the mountains there are numbers of lions, panthers, hyenas, wild boars, gazelles, and antelopes. Locusts are abundant and formidable. Ostriches are found in the deserts, on the S. borders of the country. The domestic animals are very numerous, and the inhabitants pay more attention to rearing cattle than to cultivating the ground. The number of horses is estimated at 400,000, horned cattle at 5,000,000 or 6,000,000, and sheep at 45,000,000; goats are numerous, and there are camels, mules, and asses. The native variety of sheep is much larger than that known in Europe and America and has a broad tail loaded with fat, often weighing, when the animal is well conditioned, from 80 to 50 lbs. The wool is of fine quality, and almost invariably white.—A great element of both social and political weakness in Morocco lies in the population being composed of several distinct races, of Shallooha, Berbers, Arabs, Moors, Jews, and negroes. The Shallooha inhabit the high Atlas plains S. of the capital, and seem to retain traces of a somewhat advanced civilization. They follow agriculture rather than pastoral pursuits. The Berbers claim to be the oldest inhabitants of the country; they occupy part of the Atlas and the mountains of Er Rif, which extend along the Mediterranean, where they are called Riffins, and are divided into several tribes. Such of them as live along the coast have for many ages been addicted to piracy. The Arabs form the bulk of the rural population of the plains, their progenitors having entered the country at the time of the Mohammedan conquest. Some of them cultivate the soil, and are the poorest and most oppressed portion of the population, and are called Bedonins. The Moors are found in the towns bordering upon the sea, and are supposed to be the descendants of the Mohammedans who were expelled from Spain. They are of middling size, and when young rather slender; but they grow so stout as they advance in years, that their chief physical characteristic is their corpulence. It is said that in the harems extreme corpulence is considered as the first of personal attractions. Their natural color is yellow, but from their connections with women of Soodan there are some half-breeds of a much darker complexion. They are the principal people of Morocco with whom traffic by sea is carried on, and their language is mixed up with many Spanish words. The Jews are scattered among all these nations; their condition is best among the Berbers, but they are generally much oppressed and exposed to ignominious treatment. There are many of them in the seaport and commercial towns. The negroes, who are probably less than 200,000—

number, are brought into Morocco as slaves, but many of them obtain their liberty; and as they are distinguished by fidelity, the emperor's or sultan's body guard is composed of them.—Little attention is paid to agriculture; and as the government discourages all exportation of food to Christian states, no more grain is raised than is required for internal consumption. The cultivator is only nominally assessed at $\frac{1}{4}$ part of the produce, but as the system of administration is exceedingly bad, he is in reality perfectly at the mercy of unprincipled officials, and has no inducement to raise a larger crop than is necessary to supply his wants. The rural population manufacture woollen articles for their own use. In the towns there are some manufactures, and the red caps made at Fez are worn in most countries bordering the Mediterranean. Several kinds of silk goods, linen, and leather are also manufactured at Fez, and the inhabitants are distinguished as goldsmiths, jewellers, and cutters of precious stones. Tanning is well understood, and the leather produced is superior to any made elsewhere. The tanners of Morocco can render the lion's or panther's skin as white as snow and as soft as silk; this is done by plants indigenous to the Atlas and unknown in other parts of the world. The morocco leather of the capital is yellow, that made at Tafilet green, and in Fez red. Sole leather of very good quality is made at Rabatt and Tetuan. Silks, embroidered goods, and leather are the staple manufactured goods of the capital. Carpets are chiefly made in the S. districts, and are known in Europe and America as Turkey carpets.—The commerce of Morocco is carried on by means of caravans to Mecca, across the Great Desert to Soodan and the countries of central Africa, and by sea. The greater part of the last is in the hands of the British, from the seaports along the coasts of the Mediterranean and Atlantic. In 1855 the number of vessels entered in the ports of Morocco was: Tangier, 248; Mazagan, 189; Tetuan, 111; Mogadore, 88; Saffi, 84; Casa Blanca, 79; Rabatt, 24; El Araish, 18; total, 836, tonnage 74,679. The total exports amount to about \$2,500,000 annually, and the imports to about \$2,000,000. The exports consist principally of wool, hides, skins, grain, pulse, wax, cattle, sheep, leather, and ostrich feathers; and the chief imports are cotton, linen, muslin, sugar, tea, coffee, and hardware. In 1857, 6,000 bales of American cotton were imported. Communication is extremely difficult in Morocco, as there are no roads except in the neighborhood of the towns, and very few of the rivers have bridges. The traffic is carried on by means of pack animals. The caravan which leaves Fez annually for Mecca assembles about 7 months before the great festival, and occupies that time in dealing with the inhabitants of the countries through which it passes. Indigo, cochineal, fine leather, woollen cloth, and ostrich feathers are the chief articles taken from Morocco by these caravans; and Indian and Persian silks, perfumes, &c., are

brought in return. Some pilgrims proceed by sea to Alexandria on their way to Mecca. The trade with the interior of Africa is carried on from Tafilet, and the caravans proceed as far as Timbuctoo. Salt, woollen cloth, Turkish daggers, tobacco, and looking glasses are exchanged for ivory, gold dust, ostrich feathers, pepper, indigo, and slaves. The profits on this traffic are said to be very large.—There are many schools in Morocco where the children are taught reading, writing, and passages from the Koran. There is a university, or as it is called a "house of science," at Fez, where grammar, theology, logic, rhetoric, geometry, and medicine are taught. The arts and sciences are in an exceedingly backward state. Printing is unknown; the music is barbarous; and the once famous public libraries have disappeared. The religion of Morocco is strict Mohammedanism, but Christianity, by late treaties, is tolerated.—The sultan has absolute power over the lives and properties of all his subjects. His revenues are raised by imposts on property, duties on imports and exports, monopolies, and by fines and confiscations.—The territory at present comprehended within the empire of Morocco was, together with part of Algeria, known to the ancients under the name of Mauritania. The Roman writers supposed the inhabitants of the country came from Persia, but it now seems certain that this was not the case. The Romans occupied the sea coasts of Mauritania, and it is not likely that they made any material change in the native population or their habits. From 429 to 537 the Vandals held possession of the country, and are supposed to have introduced the piratical habits which have since prevailed. The Vandals were subdued, and the country appears to have enjoyed tranquillity till toward the close of the 7th century, when the Arabs spread over N. Africa, and the natives of Morocco were either driven to the mountains, or joined with their invaders and adopted their religion and customs. By a decree of the council of Toledo the Jews were expelled from Spain about this time, and many of them sought refuge on the shores of Africa. For nearly 100 years the country remained in a state of great confusion, when Edris, a descendant of Mohammed, was recognized by the different tribes as sovereign of the N. part of Morocco. His son, who succeeded him, founded the city of Fez in 807. The S. part of the country was then in the hands of independent chieftains. In 1055 Abubekr, the chief of a sect of fanatics, was proclaimed sovereign of Morocco. His residence was in Segelmesa or Tafilet; but his grandson and successor crossed the mountains, and in 1072 laid the foundations of the city of Morocco and made it the royal residence. In 1202 Fez and some of the other districts asserted their independence, and the dynasty of Abubekr came to an end. The Mohammedan conquerors of Spain were driven back to Morocco in 1492, and the century following the country was again united under one emperor. The em-

pire was soon afterward extended to the confines of Timbuctoo, but fell to pieces in the beginning of the 17th century. Another dynasty was established in 1648, by Muley Sherif el Fiheli, king of Tafilet, whose descendants are still the reigning family. In 1814 the emperor of Morocco abolished the slavery of Christians throughout his dominions; and in 1817 he disarmed his marine and strictly prohibited piracy. In 1844 Abd el Kader, being hard pressed in Algeria, incited the Moors to make war upon the French, when the prince de Joinville bombarded Tangier and took possession of Mogadore; but upon peace being concluded the same year, that town was given up. New complications with France arose in 1851 on account of the plunder of a French vessel wrecked on the coast. Salee was bombarded by Rear-Admiral Dubourdien, Nov. 26, 1851, and peace was only concluded March 28, 1852, after compensation had been made by the sultan. The power of the sultan has been greatly weakened by internal disorders, and latterly the tranquillity of the empire has been much disturbed. The Rif pirates recommenced their depredations, and in 1856 the French government obtained compensation from the sultan, which was the first instance of redress being peaceably granted. The Spanish establishments on the coast of Morocco, at Melilla, Alhucemas, and Peñon de Velez, had repeatedly suffered from these outrages; and difficulties existed for some years in consequence between the two governments. (See Richardson's "Travels in Morocco," edited by his widow, London, 1859.) Soon after the accession of the present sultan Sidi Mohammed, who succeeded his father Abderrahman Sept. 6, 1859, the French made an incursion into the territory of Morocco, to revenge certain outrages committed along the Algerian frontier by the tribe of Beni-Suassan. The campaign lasted about a month, closing in the early part of November, and was attended with success on the part of the French. In the mean time Spain had demanded satisfaction for a series of attacks upon her commerce by the Rif pirates, and for an insult to the Spanish flag at Ceuta in Aug. 1859. The sultan disclaiming all responsibility for the acts in question, which he declared to have been committed by rebels, war was declared by Spain, Oct. 22, and a large army under command of Marshal O'Donnell was at once set in motion. The first division landed at Ceuta on the night of Nov. 18, and after repelling an attack of the enemy intrenched themselves at El Serrallo close to that city. From this time up to the close of the year the Spaniards had to sustain constant attacks on their lines, which they did not repulse without heavy losses. The sultan proclaimed a "holy war," and his soldiers fought with a courage and enthusiasm worthy of the Moors of Granada. On Dec. 30 the Spanish fleet destroyed the forts at the mouth of the river Tetuan, and on Jan. 1 O'Donnell commenced his march toward Tetuan. On the 2d Gen. Prim defeated the whole Moorish line,

40,000 strong, with a loss to the Moors of about 1,500 and to his own army of 600. About Feb. 1, O'Donnell, having consumed a month in marching a distance of 21 miles, occupied the heights about Tetuan, and on the 4th fought a great battle which resulted in the capture of the enemy's camp and the surrender of the city on the following day. For this exploit he received the title of duke of Tetuan, and a grant from Queen Isabella of the ground on which the action was fought. The remaining events of the campaign, with the exception of the bombardment of Arzila and El Araish on the Atlantic coast, were of trifling importance. On March 25 preliminaries of peace and an armistice were agreed upon, and a definitive treaty was signed April 27. The emperor guaranteed to the queen of Spain an indemnity of 20,000,000 piasters for the expenses of the war; ceded to her majesty "all the territory comprised from the sea following the heights of Sierra Bullones as far as the road of Anghera," together with other territory about Santa Cruz; granted permission for a Spanish minister to reside at Fez or wherever else might be found most convenient to Spain, and for a missionary house to be opened at Fez; and promised favorable commercial regulations. The value of the ceded territories amounts to about 300,000,000 reals.

MOROCCO, the capital of the empire of Morocco, situated on the N. side of an extensive and fertile plain 1,500 feet above the sea 4 m. S. of the river Tensift, in lat. 31° 35' N. long. 7° 36' W.; population variously estimated between 50,000 and 80,000. It is nearly 5 m. in circuit, and is surrounded by a strongly built wall of tappia work (lime beaten in a case with earth) 30 feet high, with foundations of masonry, and square towers every 50 yards. In the walls there are 11 gates. The space within is only partially built upon, and there are large gardens and open areas of from 20 to 30 acres. The streets are narrow, irregular, unpaved, and in wet weather exceedingly dirty. The houses are generally one story high, built in the same way as the walls of the city, whitewashed, and have flat roofs and terraces. The apartments front upon a court, and toward the street there are unglazed openings for windows; but the interior arrangements are much in the Spanish style. Many of the doors are of cypress wood elegantly carved. There are several open market places throughout the city, beside which there is a covered bazaar where articles of all descriptions are offered for sale. There are 19 mosques, several of which are remarkable for size and elegance. Outside the walls, on the S. of the town, stands the palace, occupying a space of about 1,500 yards long by 600 wide, encircled by a strong wall. The whole is set out in gardens, round which are detached pavilions forming the sultan's residence. The only goldsmiths, tinmen, and tailors in Morocco; they are said to be generally poor, though they make an outward appearance of prosperity. The Moors are the shoemakers, carpenters,

ters, masons, smiths, and weavers. There are several tanning and leather dyeing establishments, one of which is said to employ 1,500 hands. There are ruins of extensive aqueducts in the vicinity of the town, some of them 20 m. in length; and there are several large cemeteries outside the walls, one of which is upward of 100 acres in extent. Nearly half the town is now in ruins.

MORPHEUS (Gr. *μορφᾶν*, to shape), in Greco-Roman mythology, the son of Sleep and god of dreams. He is represented in a reclining posture, with a crown of poppies.

MORPHIA. See **OPTUM**.

MORPHY, PAUL CHARLES, an American lawyer, celebrated as a chess player, born in New Orleans, La., June 22, 1837. His grandfather was a native of Madrid in Spain, who emigrated to America and settled in Charleston, S. C. His oldest son, the father of Paul, removed to New Orleans at an early age, and studied law under Edward Livingston; he was attorney-general, twice a member of the state legislature, and afterward became a judge in the supreme court of Louisiana, and died in 1856. Paul Morphy early exhibited a fondness for the game of chess, and at the age of 10 years was taught the moves and powers of the pieces by his father; two years later he had encountered successfully the best amateurs of his native city. After fitting himself by several years' study at an academy in New Orleans, he entered St. Joseph's college in 1850, and remained there 5 years. In 1855 he entered a law school, and in 1857 was admitted to practice at the Louisiana bar when he should have completed his 21st year. During his collegiate course he had continued his interest in the game of chess, and had exhibited his already remarkable skill in various contests with Eugene Rousseau, his uncle Ernest Morphy, and Löwenthal, defeating them in a majority of games; and when in 1857 Mr. Daniel W. Fiske of New York projected the chess congress, one of his first acts was to invite the attendance of the young player. At the congress Mr. Morphy defeated in a majority of games, many being at considerable odds, the first players of the United States. In December Mr. Morphy returned to New Orleans, and shortly after published a challenge to the whole American chess community to play him at the odds of pawn and move; the challenge was never accepted. During the following season Mr. Morphy first exhibited his ability to play without seeing the board, sometimes conducting as many as 7 games at one time. In 1858 a committee of the New Orleans chess club sent a letter to Mr. Staunton, the champion of English chess, inviting him to play a match with Mr. Morphy for a stake of \$5,000, and accompanying the invitation with the agreement that should the English player lose the match, the sum of \$1,000 was to be paid him out of the stakes in reimbursement of the expenses incurred by him. Mr. Staunton declined the invitation on the ground of the distance.

Mr. Morphy afterward decided to visit England and the continent, and in June of the same year sailed from New York. In London he continued the round of success which had characterized his previous efforts, and even defeated Mr. Löwenthal, whose strength had greatly increased since their previous play; 14 games were played, of which Mr. Morphy won 9 and Löwenthal 3, 2 being drawn. Mr. Staunton, who had frequently promised to meet Mr. Morphy, postponed the conflict from day to day, and, except in consultation games, they never met. On Aug. 26 Mr. Morphy attended the annual meeting of the British chess association at Birmingham, where he played 8 games simultaneously without seeing the boards, winning 6 games and losing one, and one being drawn. In September he went to Paris, where he first played a match of 7 games with Mr. Harrwitz, winning 5 and drawing one, whereupon the match was resigned by Mr. Harrwitz on the plea of indisposition. After defeating the best French players at the *café de la régence*, including Rivière, Laroche, Journoud, and Devinck, he encountered on Dec. 20 the celebrated Adolph Anderssen, considered the champion of German chess. The result of the match was: Morphy 7, Anderssen 2, drawn 2. Mr. Morphy continued in Paris playing with his usual success until April 4, when a farewell banquet was given him, at which his bust was crowned with laurel by the French players. Leaving Paris, he returned to London, and during the remainder of his stay exhibited his power in matches and in blindfold play as before. On April 30 he sailed from Liverpool for New York. His career in Europe had been one of continued triumph. His urbanity and gentleness of manners had endeared him to all his adversaries, who exhibited their regard by public dinners and ovations wherever he went. Mr. Morphy has never adopted chess playing as a profession, and latterly he has played but rarely, devoting himself almost exclusively to his profession, the practice of which he has resumed at New Orleans.

MORRIS, a N. co. of N. J., bounded N. E. by the Pequonnock river, E. and S. E. by the Passaic, and drained by Rockaway and Whippany rivers and the head branches of the Raritan; area, 650 sq. m.; pop. in 1855, 82,498. The surface is traversed by ranges of hills, some of which, as Schooley's and W. Trowbridge mountains, reach a considerable elevation. It abounds in valuable minerals, among which are copper, iron, zinc, marble, limestone, sandstone, and manganese; there are 6 iron mines which yield large quantities of metal, giving employment to a great number of the inhabitants. The productions in 1850 were 524,866 bushels of Indian corn, 281,381 of oats, 185,271 of potatoes, 61,326 of wheat, 41,213 lbs. of wool, 774,591 of butter, and 39,091 tons of hay. There were 28 grist mills, 33 saw mills, 7 woolen factories, 3 founderies, 36 forges, 5 paper mills, 13 tanneries, 3 newspaper offices, 42

churches, and 5,589 pupils attending public schools. It is intersected by the Morris canal and the Morris and Essex railroad, the latter passing through the capital, Morristown.

MORRIS, CHARLES, an American naval officer, born in Connecticut in 1784, died in Washington, D. C., Jan. 27, 1856. He entered the navy as a midshipman in July, 1799, and during the war with Tripoli, 1801-'5, served with distinction in the squadron of Commodore Edward Preble. He prominently participated in the expedition commanded by Decatur which destroyed the frigate Philadelphia in the harbor of Tripoli on the night of Feb. 15, 1804. In Jan. 1807, he was promoted to a lieutenancy, and in the war of 1812 served as 1st lieutenant of the frigate Constitution, distinguishing himself during the chase of that ship for 8 days and nights by a British squadron in July, 1812, and by his gallantry in the action between the Constitution and Guerriere on Aug. 19, in which he received a very severe wound. He was promoted to the rank of captain, passing the grade of master commandant; and in 1814 he was appointed to the command of the Adams of 28 guns, in which ship he made an important cruise upon the coasts of the United States and Ireland, harassing British commerce very much. In August, 1814, the scurvy appeared on board, and the ship having been much injured by running on shore in thick weather upon Haute Isle, Capt. Morris entered the Penobscot river in Maine, and running up to Hampden made preparations to heave out for repairs. While engaged in this, a strong British expedition entered the river to capture the ship, and a militia force assembled for her protection giving way, nothing remained for Capt. Morris but to destroy her, which he did, directing his crew to break up into small parties and make their way for 200 m. across the thinly inhabited country to Portland. This order was strictly obeyed, every man reporting himself at Portland in due time. After the peace with England Commodore Morris continued in active employment either afloat or on shore, being off duty but about 2½ years in a professional career of 57. He served 21 years at sea, commanding four squadrons on foreign stations, 8 years in command of different navy yards, 11 years as navy commissioner, and 8 years as chief of a bureau. At the time of his death he was at the head of the bureau of ordnance and hydrography.

MORRIS, GEORGE P., an American poet and journalist, born in Philadelphia, Oct. 10, 1802. At an early age he removed to New York, where he commenced his literary career by writing for the journals, particularly the "New York Gazette" and the "American," to the first of which he contributed verses as early as his 15th year. In Aug. 1823, in conjunction with Samuel Woodworth, he commenced the publication of the "New York Mirror," which was discontinued Dec. 31, 1842, under the financial disasters of the times. It employed some of the best literary talent of the country, including

among its contributors Bryant, Halleck, Pading, Leggett, Hoffman, Fay, and Willis, and stood probably at the head of periodicals of its class. In 1843 Mr. Morris associated himself with Mr. Willis in the publication of the "New Mirror," of which 8 volumes were issued, and in 1844 established the "Evening Mirror," a daily paper, in which he was assisted by Mr. Willis and Mr. Hiram Fuller. At the close of 1845 he commenced alone a weekly journal called the "National Press," the title of which was in Nov. 1846, changed to that of the "Herald Journal," since which time it has been conducted by himself and Mr. Willis. As a song writer, however, rather than a journalist, Mr. Morris has acquired his chief reputation; and his lyrical efforts, produced at intervals during his literary career down to the present time, have gained a wide popularity. Of his "Woodman spare that Tree" several millions of copies are said to have been circulated; and others as "We were boys together," "Land-Ho!" "Long Time Ago," "The Origin of Yankee Doodle," "My Mother's Bible," "Whip-Poor-Will," &c. have proved sources of great profit to the publishers. The melodies with which many of these songs are identified have been written for them by Balfe, Sir John Stephenson, Sir Henry Bishop, and other English composers; and Malibran, Braham, Russell, Sinclair, Dempster and Madame Anna Bishop have sung them in public. Various editions of his poems have been published, including one in 1840 with illustrations by Weir and Chapman (8d ed., New York, 1843), a miniature volume in 1846 and a more complete edition in 1860. In 1853 Mr. Morris also published a volume entitled "The Deserted Bride and other Poems" (New York), and he has edited a volume of "American Melodies," consisting of songs by upward of 250 American writers, and, in conjunction with Mr. Willis, the "Prose and Poetry of Europe and America" (8vo., New York). In 1837 he produced a successful drama founded on incidents in the American revolution, entitled "Briercliff;" and in 1842 he wrote the libretto of "The Maid of Saxony," an opera set to music by Charles E. Horn. He has also published a volume of prose sketches entitled "The Little Frenchman and his Water Lilies" (1838). Mr. Morris has resided for many years at Undercliff, a country seat on the Hudson river, nearly opposite West Point, and has been a lieutenant-general in the New York state militia.

MORRIS, GOUVERNEUR, an American statesman, born in Morrisania, Westchester co., N. Y., Jan. 31, 1752, died Nov. 6, 1816. Little is known of his early years. He was graduated at King's (now Columbia) college in 1769 and immediately entered the law office of William Smith, the historian of the province. In May, 1771, he was admitted to practice. At the age of 18 he wrote a series of newspaper articles in regard to finance, which attracted much attention; and when the revolutionary war began, he had already become distinguished. It

May, 1775, he was elected a delegate to the provincial congress of New York, of which he continued a member for nearly 3 years. While in that position he made a report upon the mode of emission of a paper currency by the continental congress, which was forwarded to congress, and its leading suggestions were afterward carried out; and he was a member of the committee for drafting a constitution for the state of New York. He was elected a delegate to the continental congress in 1777, and in October joined that body, then sitting at York, Penn., and passed the following winter at Valley Forge as one of a committee appointed to examine, with Washington, into the state of the army. In Feb. 1779, he was chairman of the committee "to consider the despatches from the American commissioners abroad, and communications from the French ministers in the United States," whose report formed the basis of the treaty of peace afterward adopted; and in the same year he published a pamphlet entitled "Observations on the American Revolution." While residing in Philadelphia, in May, 1780, he was thrown from his vehicle, and his leg injured so severely as to require amputation. In July, 1781, he was chosen by Robert Morris as assistant superintendent of finance, which office he held for 8½ years. After the revolution he began again the practice of law, and also engaged with Robert Morris in mercantile speculations. On the death of his mother in 1786, he purchased the patrimonial estate at Morrisania from his brother. In 1787 he published an address to the assembly of Pennsylvania, taking strong ground against the projected abolition of the bank of North America. He was a delegate from Pennsylvania to the U. S. constitutional convention of 1787, in which he took a conspicuous part; he was one of the committee of 5 appointed to draft the constitution, and according to Madison the finish given to the style and arrangement of that instrument fairly belongs to him. Mr. Morris sailed for France on business in Dec. 1788, and while there kept a minute diary, full of valuable details. In 1791 he was appointed by Washington secret agent to England in order to settle unfulfilled terms of the old treaty; he remained in London till September, but his efforts were not attended by any result. In 1792 he was appointed minister plenipotentiary to France, and during the revolution conducted himself with great prudence, although his sympathies were not with the more democratic side. He served until Oct. 1794, when he was recalled at the request of the French government, travelled in Europe until the autumn of 1798, and while at Vienna endeavored to effect the liberation of Lafayette from his prison at Olmütz. In 1800, having taken up his residence at Morrisania, he was elected by the legislature of New York to fill a vacancy in the U. S. senate, and served with distinction in that body until 1803, acting then and afterward with the federalists. He spent the latter years of his life in retirement,

dispensing a liberal hospitality, and maintaining a correspondence with literary and public men in Europe and America. He delivered funeral orations on Washington, Hamilton, and Gov. George Clinton; in 1812 an oration before the New York historical society; in 1814 an address in celebration of the deliverance of Europe from the yoke of military despotism, which attracted attention on account of its peculiar views; and in 1816 an inaugural oration before the historical society on his appointment as president. He was a powerful orator, and possessed an excellent delivery, though his style was somewhat florid. In person his resemblance to Washington was so close that he stood as a model of his form to the sculptor Houdon. Mr. Morris was one of the earliest promoters of the project for constructing the Erie canal, and in the summer of 1810 he examined the route to Lake Erie. He was chairman of the canal commissioners from their first appointment in March, 1810, until near the end of his life. His life, with selections from his correspondence and miscellaneous papers, has been written by Jared Sparks (3 vols. 8vo., 1832).

MORRIS, Lewis, one of the signers of the declaration of independence, born at Morrisania, Westchester co., N. Y., in 1726, died Jan. 22, 1798. After being graduated at Yale college in 1746, he engaged in farming on a very extensive scale on his paternal estate at Morrisania. He took strong ground against the act of parliament compelling the inhabitants of the province of New York to furnish with supplies the foreign troops quartered upon them. He was elected to the congress of 1775, and was a member of the committee to devise means for supplying the colonies with munitions of war. After the close of the session he was sent west to detach the Indians from the British. In 1776 he resumed his seat in congress, and signed the declaration of independence, although his estate was at that time in the hands of the enemy. As a consequence his manor was laid waste, and his family expelled. In 1777 he was succeeded in congress by Gouverneur Morris, his half brother, but afterward served in the state legislature. The latter part of his life was spent at Morrisania. He was one of the boldest and most zealous promoters of the revolution.

MORRIS, ROBERT, an American financier, and one of the signers of the declaration of independence, born in Lancashire, England, Jan. 20, 1734, died in Philadelphia, May 8, 1806. When 13 years old he came to America, and before he was 15 was placed in the counting house of Charles Willing, a merchant of Philadelphia. In 1754 he entered into partnership with the son of his employer. The firm continued until 1793, and at the beginning of the revolution was more largely engaged in commerce than any other in Philadelphia. Mr. Morris zealously embraced the American cause, opposed the stamp act, and signed the non-importation agreement of 1765, in consequence of which his business suffered seriously. He was

elected a delegate to the congress of 1775, and served on the committees to devise ways and means for furnishing the colonies with military stores and with a naval armament, and was a member of the naval committee appointed to carry the plan of such an armament into execution. On July 1, 1776, he voted against the declaration of independence, and on the 4th refused to vote at all, considering the time inappropriate. He was reelected to congress on the 20th of the same month, and again in 1777. At this period he was largely employed in managing the fiscal affairs of the country. On his personal responsibility he frequently borrowed large sums for the use of the government, which, on account of the known state of the treasury, could not have been procured in any other way. During the session of congress at York, Penn., it was insinuated that the house of Willing, Morris, and co. had been engaged in fraudulent proceedings to the detriment of the public; but in the investigation which followed, it was entirely exonerated from suspicion. In 1780 Mr. Morris, in conjunction with other citizens of Philadelphia, established a bank, by means of which 8,000,000 rations of provisions and 300 hogsheads of rum were forwarded to the army. On Feb. 20, 1781, he was unanimously elected superintendent of finance, and by subsequent resolutions of congress was invested with almost the entire control of the financial affairs of the government. At this time the treasury was more than \$2,500,000 in debt, the army was destitute, and the credit of the country exhausted. One of his first acts was to establish the bank of North America, which was incorporated by congress Dec. 31, 1781, and went into operation Jan. 7, 1782, with a capital of \$400,000. Pennsylvania and several other states soon afterward passed laws to protect and facilitate its operations; and it proved very efficient in relieving the government of its embarrassments. During the financial administration of Mr. Morris, he several times pledged his private credit for public supplies, being reputed much wealthier than he really was. In the beginning of 1781 he furnished the suffering army with several thousand barrels of flour; and in the campaign of that year he supplied nearly every thing required for the expedition against Cornwallis. For this purpose he issued his own notes to the amount of \$1,400,000, which were finally all paid. But, harassed by the claims of the public creditors, and indignant at the indisposition of the several states to fulfil their engagements, Mr. Morris, in Jan. 1783, informed the president of congress that, as nothing but the public danger could have induced him to accept the office of superintendent of finance, so little apprehension was now entertained of the common enemy that his original motives had ceased to operate; that circumstances had postponed the establishment of the public credit; and that it did not consist with his ideas of integrity to increase the national debt while the prospect of paying it was dimin-

ishing. He therefore resigned, but consented to serve until May 1, and did not finally withdraw until Nov. 1784. On May 6, 1784, congress at his urgent request appointed a board of three commissioners to superintend the treasury, and a committee to inspect the conduct of the department. In giving an account of his administration, he published a long and able address to the people of the United States. Before he resigned he issued a public notice pledging himself personally to provide for his various engagements in behalf of the government. On Sept. 7, 1781, congress had resolved that an agent of marine should be appointed all the duties of that office should devolve upon the superintendent of finance; and no agent being appointed, Mr. Morris was unwillingly compelled to regulate the affairs of the navy until the close of 1784. The charter of the bank of North America having been annulled by the assembly of Pennsylvania, he was one of the representatives sent from Philadelphia in 1786 to the legislature for the purpose of obtaining a renewal. The effort failed of success then; but in the succeeding legislature the charter was renewed. In 1787 he was elected a member of the convention which framed the federal constitution; and on Oct. 1, 1788, he was elected a member of the first U. S. senate. The post of secretary of the treasury was offered to Mr. Morris by Washington, but was refused, and on being asked to designate a person for the station, he named Alexander Hamilton. On the conclusion of the war he was one of the first to engage in the East India and China trade, forming a partnership for that purpose with Gouverneur Morris, and in the spring of 1784 sent to Canton the first American vessel that ever appeared in that port. In his old age he engaged largely in land speculation, in consequence of which he lost his fortune, and during the latter years of his life was confined in prison for debt. Although he received only an English education, Mr. Morris was an impressive public speaker and an able writer.

MORRIS, THOMAS, an American statesman, born Jan. 8, 1776, died Dec. 7, 1844. He was the son of a Baptist minister of Welsh descent, and his early life was passed in western Virginia, whence he removed in 1795 to Columbus, O., and was employed by the Rev. John Smith, the first senator in congress from Ohio. Having married, he fixed his residence in 1800 in Canton, Mont. co., O., studied law, was admitted to the bar, was a member of the state legislature from 1806 to 1830, was chosen a judge of the supreme court, and in 1832 was elected a senator in congress, where he distinguished himself as an opponent of slavery, and was engaged in important debates with Mr. Calhoun and Mr. Clay in defence of the right of petition and the duty of the general government to discourage slavery. His anti-slavery sentiments were distasteful to the democratic party, by which he had been elected, he was not reelected, and retired from congress in March, 1839. In 1844

1848, the liberty party at Buffalo nominated him for vice-president, with James G. Birney for president. He died a month after the election. Dr. Gamaliel Bailey in announcing his death said: "He was one of the most energetic and independent of our politicians. The cause of human rights, to which he had devoted his latter days, has lost one of its most fearless champions. His noble stand in defence of liberty in the United States can never be forgotten." His life and speeches have been published by his son, the Rev. B. F. Morris.

MORRIS, THOMAS A., D.D., an American clergyman, and bishop of the Methodist Episcopal church, born in Kanawha co., Va., April 28, 1794. He was received as a travelling preacher into the Ohio conference in 1817; was ordained deacon by Bishop George, and subsequently as an elder by Bishop Roberts; was an itinerant preacher in Ohio, Kentucky, and Tennessee, and when the "Western Christian Advocate" was established at Cincinnati in 1838, was elected as its editor, which post he filled with great credit until 1886, when he was elected by the general conference a bishop of the M. E. church. The degree of D.D. was conferred upon him by McKendree college, Ill., in 1841.

MORRIS DANCE, an old English dance, usually performed with castanets, tabors, staves, or swords, by young men lightly dressed, with bells fixed about their legs, and parti-colored ribbons streaming from their arms and shoulders. It is supposed to be derived from the Morisco or Moorish dance, which is still popular in Spain under the title of the fandango. It may have been introduced into England when John of Gaunt returned from Spain in the reign of Edward III., but Douce believes it to have been borrowed from the French or Flemings. It can be traced as early as the reign of Henry VII., when it was one of the sports not only of May day, but of other festivals, as holy Thursday, the Whitsun ales, and weddings. In the May games the morris was often performed by Robin Hood, Little John, Friar Tuck, Maid Marian, the fool, Tom the piper, and the hobby-horse. The May festivities of Robin Hood were chiefly designed for the encouragement of archery, and it is not certain that either he or his companions were prominent in the dance, which was an entirely distinct merriment. Maid Marian is supposed to represent his mistress, but the part was often filled by a boy dressed in a girl's habit, who was queen of the May. It was once usual for the queen to be splendidly attired, but after the degeneracy of the dance the character was personated by a clown who obtained the name of Malkin. Friar Tuck maintained his place in the sport till the reign of Elizabeth, but is not heard of afterward. The fool bore as badges of his office a bauble in his hand, and a cockcomb hood with asses' ears on his head. Tom the piper was a minstrel of the superior order, with a complicated red, blue, and yellow dress, a sword, a feather in his cap, and a tabor, ta-

bor stick, and pipe to distinguish his profession. The hobby-horse was designed for antics and tricks of legerdemain. A curious tract appeared in 1609 describing a morris dance in Herefordshire, in which the combined ages of the 12 performers was 1,200 years. Mr. Brand describes a recent celebration in the same place by 8 men whose combined ages were 800 years. During the reign of Elizabeth the Puritans checked the May pastimes by their invectives against "the terrestrial furies" which indulged in them. Friar Tuck, Maid Marian, and the hobby-horse were declared remnants of popish and pagan superstition. The last two were restored by King James's "Book of Sports," but were again degraded during the commonwealth. The morris dance has, however, continued in parts of England nearly to the present time. Shortly before the first revolution in France it was celebrated in many parts of that country, accompanied by a fool and a hobby-horse (*un chevalot*).—The fullest account of the subject is that by Douce, in a dissertation accompanying his "Illustrations of Shakespeare."

MORRISON, ROBERT, D.D., an English missionary, born in Morpeth, Northumberland, Jan. 5, 1782, died in Canton, Aug. 1, 1834. After receiving an elementary English education, he was apprenticed to his father as a last maker; but having studied religious books during his leisure hours, he entered on a regular theological course in 1801, under a Presbyterian clergyman of Morpeth, who in 1803 obtained him admission into the Independent academy at Hoxton. In 1804 he offered his services to the London missionary society; and his offer being accepted, he removed in 1805 to the mission college at Gosport, and commenced the study of Chinese. In the winter of 1807 he was ordained, and in the following autumn arrived at Canton. The next year he was nominated translator to the East India company's factory at Canton, and at the same time was making preparations for translating the Scriptures into Chinese. The New Testament appeared in 1814, and the Old Testament, executed with the assistance of Mr. Milne, in 1818. In November of the latter year Mr. Morrison caused the foundation of an Anglo-Chinese college at Malacca. In 1823 he returned to England, where the royal society admitted him to membership. In 1826 he sailed once more for China, and there passed the rest of his life. His Chinese grammar (4to., Serampore, 1815) and his Chinese dictionary (5 vols., Macao, 1815-'23) were his chief original works. His "Memoirs," compiled by his widow, were published in London in 1839, in 2 vols. 8vo.

MORRISTOWN, the capital of Morris co., N. J., on the Whippany river, and on the Morris and Essex railroad, 50 m. N. N. E. from Trenton, and 23 m. by railroad from New York; pop. of the township in 1860, 6,024. The village is built on an elevated plain commanding beautiful views of the surrounding country. The streets are regularly laid out, the houses neatly built,

and there is a public square in the centre. It contains a court house, 2 banks, an academy, several manufactories, and 7 churches (1 Baptist, 2 Episcopal, 1 Methodist, 2 Presbyterian, and 1 Roman Catholic).

MORROW, a central co. of Ohio, drained by the head streams of Vernon and Olentangy or Whetstone rivers; area, 870 sq. m.; pop. in 1850, 20,280. The surface is undulating and the soil highly fertile. The productions in 1850 were 866,679 bushels of Indian corn, 81,925 of wheat, 173,795 of oats, 19,428 tons of hay, and 134,895 lbs. of wool. There were 8 grist mills, 14 saw mills, 1 foundery, 56 churches, and 1,268 pupils attending public schools. It is intersected by the Cleveland, Columbus, and Cincinnati railroad. A large quarry of freestone is worked near the capital, Mount Gilead.

MORROW, JEREMIAH, a western pioneer, born in Pennsylvania in 1770, died in Ohio, March 22, 1852. In 1795 he removed to the North-West territory, and in 1802 was elected a delegate to the convention for forming the state constitution of Ohio. He was the first representative in congress from that state, and then served as U. S. senator from 1813 to 1819. From 1822 to 1826 he was governor, then canal commissioner, and from 1841 to 1843 was again a member of congress.

MORSE. See WALRUS.

MORSE. I. JEDIDIAH, D.D., an American clergyman and geographer, born in Woodstock, Conn., Aug. 28, 1761, died in New Haven, June 9, 1826. He was graduated at Yale college in 1783; was licensed to preach in 1785, by the New Haven association of Congregational ministers; in 1786 was tutor in Yale college; the same year was ordained a minister of the gospel; and in 1789 was installed as pastor of the first Congregational church in Charlestown, Mass. In 1794 he received the honorary degree of D.D. from the university of Edinburgh. He was an active member of the Massachusetts historical society, and numerous other literary and scientific bodies. Dr. Morse is known as the father of American geography. He prepared in 1784, at New Haven, for the use of a school of young ladies, a small 18mo. geography, which was the first work of the kind published in America. This was followed by larger works in the form of systems of geography and gazetteers containing full descriptions of the country from materials obtained by travelling and extensive correspondence. Jeremy Belknap, the historian of New Hampshire, Thomas Hutchins, geographer-general of the United States, Ebenezer Hazard, and others, who had contemplated the same task, gracefully yielded their pretensions in his favor, even contributing to his use the materials they had gathered; and for 30 years he remained without an important competitor in this department of science. Reprints of the early editions of his larger geographical works were published in Great Britain, and French and German translations of them in Paris and Hamburg. Much of Dr. Morse's life was

spent in religious controversy—in maintaining the orthodox faith in the New England churches against the approaches of Unitarianism. For this purpose, among other measures, he engaged actively in the enlargement in 1804 of the Massachusetts general association of Congregational ministers, a body whose basis is the Westminster assembly's catechism; in 1805, as a member of the board of overseers, he opposed, though unsuccessfully, the election of the Rev. Henry Ware, D.D., to the Hollis professorship of divinity in Harvard college; the same year he established, and for the 5 following years conducted, as sole editor, the "Panoplist," a monthly religious journal; he was a prominent actor in the establishment of the theological seminary at Andover, especially by his successful efforts to prevent the threatened establishment of a rival institution at Newbury, projected by the Hopkinsians, and to effect a union between them and other Calvinists on their common symbol, the assembly's catechism, the articles of this union still constituting substantially the basis of the Andover seminary, and being signed in his own study in Charlestown, in the night of Nov. 30, 1807, by himself, Dr. Samuel Spring, and Dr. Eliphalet Pearson, the three men empowered for the purpose by the wealthy donors; he participated in the organization of the Park street church in Boston in 1808, when all the Congregational churches of that city, except the Old South church, had abandoned the primitive faith of the fathers of New England. His persevering opposition to the so-called "Liberal" views of religion brought on him a persecution, which affected deeply his naturally delicate health; and in 1820 he resigned his pastoral charge, for the quiet of his New Haven home, which he occupied till his death. In 1820 he was commissioned by the U. S. government to visit the Indian tribes on our N. W. borders; and the record of his labors, embodied in a 8vo. volume of 400 pages, was published in 1822 under the title of "Indian Report," &c. Beside numerous editions of his geographical works, Dr. Morse also published "A Compendious History of New England," in conjunction with Elijah Parish, D.D. (Cambridge, 1804; 3d ed. enlarged, 1820); "Annals of the American Revolution" (Hartford, 1824); and, from 1799 to 1821, 25 sermons and addresses on special occasions. II. SAMUEL FINLEY MORSE, an American artist and inventor, the eldest son of the preceding, born in Charlestown, Mass., April 27, 1791. He was graduated at Yale college in 1810, and went to England with Washington Allston in 1811 to study painting under his tuition and that of Benjamin West. In 1815 he received the gold medal of the Adelphi society of arts at the hands of the duke of Norfolk for an original model of a "Dying Hercules," his first attempt at sculpture. He returned to the United States in 1815, and in 1824-'5, with some other artists of New York, organized a drawing association, which, after two years' struggle against various obstacles, resulted in

the establishment in 1826 of the present "National Academy of Design." Mr. Morse was chosen its first president, and was continued in that office for 16 years. In 1829 he visited Europe a second time to complete his studies in art, residing for more than 8 years in the principal cities of the continent. During his absence abroad, he had been elected to the professorship of the literature of the arts of design in the university of the city of New York; and in 1835 he delivered a course of lectures before that institution on the affinity of those arts. While a student in Yale college Mr. Morse had paid special attention to chemistry, under the instruction of Prof. Silliman, and to natural philosophy under that of Prof. Day; and these departments of science, from being subordinate as a recreation, at length became a dominant pursuit with him. In 1826-'7 Prof. J. Freeman Dana had been a colleague lecturer in the city of New York with Mr. Morse at the Athenæum; the former lecturing upon electro-magnetism and the latter upon the fine arts. They were intimate friends, and in their conversations the subject of electro-magnetism was made familiar to the mind of Morse. The electro-magnet on Sturgeon's principle (the first ever shown in the United States) was exhibited and explained in Dana's lectures, and at a later date, by gift of Prof. Torrey, came into Morse's possession. Dana even then suggested by his spiral volute coil the electro-magnet of the present day; this was the magnet in use when Morse returned from Europe, and it is now used in every Morse telegraph throughout both hemispheres. He embarked in the autumn of 1832 at Havre on board the packet ship Sully; and in a casual conversation with some of the passengers on the then recent discovery in France of the means of obtaining the electric spark from the magnet, showing the identity or relation of electricity and magnetism, Morse's mind conceived not merely the idea of an electric telegraph, but of an electro-magnetic and chemical recording telegraph, substantially and essentially as it now exists. The testimony to the paternity of the idea in Morse's mind and to his acts and drawings on board the ship is ample. His own testimony is corroborated by all the passengers (with a single exception) who testified with him before the courts, and was considered conclusive by the judges; and the date of 1832 is therefore fixed by this evidence as the date of Morse's conception, and realization also, so far as drawings could embody the conception, of the telegraph system which now bears his name. But though thus conceived and devised as early as 1832, in the latter part of which year, on reaching home, he made a portion of the apparatus, yet circumstances prevented the complete construction of the first recording apparatus in New York city until the year 1835; and then it was a rude single apparatus, sufficient indeed to embody the invention, and enable him to communicate from one extremity of two distant points of a circuit of half a mile, but not back

again from the other extremity. This first instrument was shown in successful operation to many persons in 1835 and 1836. For the purpose of communicating from, as well as to, a distant point, a duplicate of his instruments was needed, and it was not until July, 1837, that he was able to have one constructed to complete his whole plan. Now he had two instruments, one at each terminus, and could therefore communicate both ways; whereas before, with but one instrument, he could signal to one terminus only, and receive no answer. Hence, early in Sept. 1837, having his whole plan thus arranged, he exhibited to hundreds the operation of his system at the university in New York. From the greater publicity of this latter exhibition, the date of Morse's invention has erroneously been fixed in the autumn of 1837, whereas he has been proved by many witnesses to have operated successfully with the first single instrument as early as Nov. 1835. After the summer of 1837 it was in a condition to be submitted to the inspection of congress; and consequently we find Mr. Morse in the latter part of that year, and at the beginning of 1838, at Washington, asking that body for aid to construct an experimental line from Washington to Baltimore to show the practicability and utility of the telegraph. Although the invention, by its successful results before the congressional committees, awakened great interest, yet from the scepticism of many, and the ridicule of others, it was doubtful whether the favorable report of the committee would command a majority of congress in its favor. The session of 1837-'8 closed without any result, when the inventor repaired to England and France, hoping to draw the attention of the European governments to the advantages of his invention to them, and also to secure a just reward to himself. The result of this visit was a refusal to grant him letters patent in England, and the obtaining of a useless *brevet d'invention* in France, and no exclusive privilege in his invention in any other country. He returned home to struggle again with scanty means for 4 years, not discouraged, but determined to attempt again to interest his countrymen in behalf of his invention. The session of congress of 1842-'3 was memorable in Morse's history, as one of persevering effort on his part, under great disadvantages, to obtain the aid of congress; and his hope had expired on the last evening of the session, when he retired late to bed preparatory to his return home the next day. But in the morning—the morning of March 4, 1843—he was startled with the announcement that the desired aid of congress had been obtained in the midnight hour of the expiring session, and \$30,000 placed at his disposal for his experimental essay between Washington and Baltimore. In 1844 the work was completed, and demonstrated to the world the practicability and the utility of the Morse system of electro-magnetic telegraphs. In the 16 years since its first establishment, its lines have gone throughout North and parts of South America, to the

extent of more than 36,500 miles. The system is adopted in every country of the eastern continent; in Europe, exclusively on all the continental lines, from the extreme Russian north to the Italian and Spanish south; eastward through the Turkish empire; south into Egypt and northern Africa, and through India, Australia, and parts of China. Some estimate of the immense value of Morse's invention to the world may be formed from the fact that the telegraph in France alone, in the first 8 years of its infancy, brought to the public revenue the sum of 6,000,000 francs, while the old system of telegraphs in France on the semaphore principle was an annual expense to that government of 1,100,000 francs. Honors have been showered upon him by European sovereigns and governments. It is doubtful if any American ever before received so many marks of distinction. In 1848 Yale college conferred on him the complimentary degree of LL.D.; and in the same year he received the decoration of the *Nishan Istichar* in diamonds from the sultan of Turkey. Gold medals of scientific merit were awarded him by the king of Prussia (set in a massive gold snuff box), the king of Würtemberg, and the emperor of Austria. From the emperor of the French he received in 1856 the cross of chevalier of the legion of honor; in 1857 from the king of Denmark the cross of knight of the Dannebrog; and in 1858 from the queen of Spain the cross of knight commander of the order of Isabella the Catholic. He is also a member of many European and American scientific and art academies. The latest as well as the most distinguished honor that has been conferred on him is an honorary gratuity bestowed by various European governments, whose representatives met at the instance of the present emperor of the French in Paris, to consider the best means of giving the inventor a collective testimonial. Ten states, namely, France, Russia, Sweden, Belgium, Holland, Austria, Sardinia, Tuscany, the Holy See, and Turkey, were represented; their deliberations at two sessions resulted in a vote of 400,000 francs, as an honorary and personal reward to Mr. Morse for his useful labors. In 1856, the telegraph companies of Great Britain united to give Mr. Morse a banquet in London, at which Mr. William Fothergill Cooke presided; and in Paris, in 1858, another banquet was given him by Americans, numbering more than 100, and representing almost every state in the Union. Submarine telegraphing was originated also with Prof. Morse, who laid the first submarine telegraph lines in New York harbor in the autumn of 1842, and received at the time for that achievement. In a letter from Mr. Morse to the secretary of the U. S. treasury, dated Aug. 10, 1843, it is believed occurs the first suggestion of the project of the Atlantic telegraph. Professor Morse has his summer residence at Poughkeepsie, on the banks of the Hudson river, and his winter residence in New York city.

III. SIDNEY EDWARDS, an American jour-

nalist and geographer, brother of the preceding, born in Charlestown, Mass., Feb. 7, 1794. He was admitted to the freshman class of Yale college in Sept. 1805, when only 11 years of age, and was graduated in 1811. In 1812-13 he wrote a series of articles for the Boston "Columbian Centinel," illustrating the danger to the American Union from an undue multiplication of new states in the South, and showing that it would give to a sectional minority the control of the government. In 1815, while pursuing his studies at the law school in Litchfield, Conn., Mr. Morse was invited by distinguished orthodox clergymen and laymen in the vicinity of Boston to establish a new weekly newspaper in that city; and after consultation, especially with his father and the late Jeremiah Evans, he prepared the prospectus of the "Boston Recorder," the prototype of that numerous class of journals now so widely established in America and Europe termed "religious newspapers." Mr. Morse was the sole editor and proprietor of the "Recorder" until its income was more than adequate to the payment of all the mechanical expenses; and when he left it, at the end of 15 months, its circulation was greater, with one or two exceptions, than that of any other Boston newspaper. In 1817 Mr. Morse invented, in connection with his elder brother, and patented the flexible piston pump. In 1820 he produced a 12mo. school geography; and in 1822 an 8vo. geography, which was used as a text book in several American colleges. In May, 1823, in connection with his younger brother Richard C. Morse, he established the "New York Observer," now the oldest weekly newspaper in that city, and the oldest religious newspaper in the state of New York. In 1834 he conceived the idea of a new mode of engraving applicable especially to the production of plates for printing maps in connection with type under the common printing press; and after 5 years of experiment he succeeded in June, 1839, with the aid of his assistant, Mr. Henry A. Munson, in producing by the new art, which he named cerography, maps and prints that elicited the praises of artists and editors in all parts of the land. One of the first applications of cerography was to the illustration of a school geography written by the inventor, of which more than 100,000 copies were printed and disposed of during the first year. The art of cerography has never been patented, nor has the process been revealed to the public, the inventor regarding it as still imperfect and capable of great improvement.

MORTALITY, BILLS OF. See BILLS OF MORTALITY.

MORTAR, in artillery, a short cannon of large bore made of brass or iron, chambered and used for throwing shells filled with powder, called bombs. For this purpose it is usually raised at an angle of 45°. It is supposed that the earliest made cannon were of the form known as mortars; and these were originally used for throwing shot. They are said to have been employed in 1494, when Naples was be-

sieged by Charles VIII., but whether for throwing shells or shot is not known. Cyprian Lucas describes their use for throwing bombs in 1588 at the siege of Wachtendonk in Gelderland by the earl of Mansfeld. As used in the English service, there are 3 sizes of iron and 2 of brass mortars, the former being respectively of 18 inch, 10 inch, and 8 inch bore; and the brass of 5½ and 4½ inch. The 10 inch iron mortars are preferred for almost all service, though those of 18 inches are also much used. For sea service they are made stronger than others of the same bore designed for use on the land. Attempts that have been made by the French and others to introduce them of very large size have proved unsuccessful. One employed at the siege of Antwerp fired only 10 or 12 shots, and with comparatively little effect; and not long after it burst when charged very moderately. One of 36 inches bore, and weighing over 50 tons 18 cwt., was constructed by Mr. Mallet for the British government at an expense of more than £8,000. It was intended to carry a shell which before being filled weighed 26 cwt. 2 qrs. The body of the piece was formed of heavy rings of wrought iron nicely fitted into each other, and all bound down to a solid cast iron breech end by huge ribs or staves of wrought iron. This piece also is regarded as a failure.

MORTAR, in domestic and chemical uses, a utensil in which articles are crushed and ground to powder by the use of the instrument belonging to the mortar called the pestle. Various materials are employed for making mortars, as iron, stone, porcelain, glass, and for those used in chemical operations steel and agate. The last named, by its extreme hardness, cleanliness, and resistance to the action of chemical agents, is admirably adapted for this purpose. The supplies of these come chiefly from Oberstein on the Nahe, where the manufacture of them is largely carried on in numerous mills. The rough gates for this use are found in the mountains near by, and are brought from Brazil and other foreign countries to be converted into this and various other articles. Steel mortars are used for crushing particles of diamonds and other very hard substances, the powder of which is required for analysis or other use. They consist of a flat circular base with a depression in the upper side for receiving a short smoothly turned hollow cylinder of steel, open at both ends. This being set in its place, the particles are introduced, and a tightly fitting piston of steel is driven down upon them with a mallet.

MORTAR, a cement of lime and sand. See **CEMENT**.

MORTGAGE (Fr. *mort*, dead, and *gage*, pledge; Lat. *vadium mortuum*). Chancellor Kent defines a mortgage to be "the conveyance of an estate by way of pledge for the security of a debt, to become void on payment of it." The old law writers Glanville and Spelman say that mortgage is so called because, between the time of making the conveyance and the time

appointed for payment of the debt, the creditor by the old law received the rents of the estate to his own use, or that these rents were dead or lost to the mortgageor. Littleton gives another derivation of the word, viz.: "If the feoffor doth not pay the sum due at the day limited, then the land which is put in pledge upon condition for the payment of the money is taken from him, and so dead to him upon condition." This derivation is the one usually adopted; though the former has been sometimes preferred, not only because the idea which it conveys of the mortgage, or *vadium mortuum*, is directly opposed to that of the *vadium vivum*, an old form of security no longer in use, in which the accruing rents were applied to diminish the debt; but also because it illustrates the intention which mortgages were first probably designed to effect. For in the times when the exaction of interest was esteemed usurious and was prohibited by the law, this conditional alienation was devised, not at all with the design of depriving the mortgageor of his property if he failed to repay the money, but that the mortgagee might in the mean time receive the rents to his own use in lieu of what he would otherwise have received as interest.—In reviewing the law of mortgage it will be convenient to examine successively the creation and nature of a mortgage with its incidents; the respective estates of the mortgageor and mortgagee; payment and extinguishment of the mortgage; and finally, the correlative rights of redemption and foreclosure. A mortgage of lands was generally created by a conveyance of lands from a debtor to his creditor, with a condition that if a sum of money were paid on a certain day the conveyance should be void, and the debtor might have his former estate. But a mortgage might also be made by an absolute deed of conveyance and a defeasance back to the grantor. This defeasance was a separate instrument defeating the principal deed by making it void if the condition was performed. This form of mortgage was however liable to accident and abuse, and has been generally disapproved by the courts. The former mode was by far the more usual. The maxims of the common law were strictly applied to this kind of conveyance; and if the money were not paid at the very day specified in the deed, the lands were absolutely forfeited, nor would a subsequent tender of the money avail the debtor. But the mortgaged lands were plainly only intended as security for the payment of the money borrowed; and large estates were sometimes pledged for the payment of small debts. A strict forfeiture in such cases was not only inconsistent with the plain principles of justice, but was contrary to the spirit of the contract. For these reasons the court of chancery interposed, and by an equitable construction mitigated the severity of the common law. (See **EQUITY OF REDEMPTION**.) Hence the condition in these cases came to be regarded as in the nature of a penalty, against which a just relief should be given. The con-

dition was intended merely as a means of enforcing the performance of the contract, and if this end were substantially attained there could be no right to use these means for an ulterior object prejudicial to the other party. Whenever therefore a failure to pay at the time appointed could be subsequently compensated, the injured party should be compelled to accept this equivalent for his loss. The doctrine finally prevailed, that although the conditions were not strictly performed, yet if the debtor, within a reasonable time, paid the debt with interest, he should be entitled to call on his creditor for a reconveyance of the lands. But on the other hand, chancery gave to the mortgagee, after reasonable indulgence to the mortgageor, the right to call upon the latter for the payment of the debt, or in default thereof to be for ever foreclosed or excluded from any further right of redemption. The right of redemption is considered in equity to be an inseparable incident of every mortgage, and it cannot be abridged by any agreement whatever. From mortgages, however, in respect to restrictions of the equity of redemption, must be distinguished sales with agreements to repurchase, or, as they are usually termed, conditional sales. In their forms, the two transactions are often very similar, and it is difficult to distinguish them. The difference is, that one is only security for a debt, while the other is a regular purchase, for a price paid or to be paid, to become absolute on a particular event. Equity will construe the agreement very strictly, and will pronounce for a mortgage if possible, in order to save the right of redemption; yet if there appear clearly to have been a sale, it will be maintained, and the right of redemption restricted to the time agreed upon.—The solicitude of the court of chancery to protect the rights of the mortgageor must not invade the right of the mortgagee. He has a plain right to his debt or its equivalent value. As a means of securing that, he is often empowered by the mortgage deed to make sale, on a breach of the condition, of the mortgaged premises, pay his debt from the proceeds, and account with the mortgageor for the balance. A power of this kind is now very frequently inserted in mortgage deeds, though it was for a long time seriously questioned and resisted as an infringement of the mortgageor's carefully guarded privilege of redemption. Its validity is now unquestioned. It concerns only the mortgagee's remedy, and under its exercise no right of the mortgageor is either forfeited or sacrificed. In legal phraseology, it is a power coupled with an interest. It is therefore irrevocable, and may be exercised after the death of the mortgageor. It is appendant to the mortgagee's estate, and as part of the mortgage security vests in any person who by assignment or otherwise becomes entitled to the money. In cases free from all doubt it may be exercised, and will be protected if exercised with due caution and in perfectly good faith; but a sale under it will be avoided for the slightest abuse.—The mode of creating a mortgage in

most of the states is to give an obligation for the money due, either by bond or by a promissory note, and a separate deed of conveyance, containing the proviso that if the money be paid on a certain day, then the deed, as also the obligation, shall be void. When, however, as is in some states the case, no separate obligation is given, the question arises whether the mortgagee may have a personal action for the money, or whether his sole remedy is against the land. It is generally construed that the deed is merely evidence of a lien upon the land, but an action will lie for the debt if that be sufficiently admitted in the deed, or even be supported by evidence outside of it. In New York, the creditor's remedy is confined to the land, if the deed contains no express covenant for the payment of the money, and there be no separate agreement to do so. Upon the execution of the deed by which a mortgage is created the legal estate is immediately vested in the mortgagee; and if there be no private agreement or statute provision to the contrary, he may at once enter into the enjoyment of his estate. Technically speaking, the mortgageor is no longer owner and has no right to further possession; and if he do remain, he is in construction of law only a tenant to the mortgagee, and may be ejected at his election even before default of payment. But in view of the intentions which the mortgage is designed to accomplish, the courts have adopted a more equitable doctrine. It cannot be more clearly expressed than in the language of Chief Justice Shaw, who says: "The first great object of the mortgage is, in the form of a conveyance in fee, to give to the mortgagee an effectual security by the pledge of real estate for the payment of the debt or the performance of some other obligation. The next is to leave to the mortgageor, and to purchasers, creditors, and all others claiming derivatively through him, the full and entire control, disposition, and ownership of the estate, subject only to the first purpose, that of securing the mortgagee." Hence it is that as between the mortgageor and mortgagee the mortgage is to be considered a conveyance in fee, because that construction best secures the latter in his remedy and in his ultimate rights to the estate and to the incident rents and profits. But in all other respects until foreclosure, when the mortgagee becomes the absolute owner, the mortgage is deemed to be a lien or charge, subject to which the estate charged may be conveyed, attached, and in other respects dealt with as the estate of the mortgageor; and all statutes upon the subject are to be so construed, and all rules of law whether administered in law or in equity are to be so applied, as to carry these objects into effect. So that until decree of foreclosure, even after default of payment at the time appointed, the mortgageor is the real owner, his equity of redemption is descendible, devisable, and alienable, just like an absolute estate of inheritance. It is the natural consequence of this view of the mortgageor's estate that the title of the mortgagee should be regarded as

as an estate in lands, but as a mere chattel interest. So long as the mortgageor's right of redemption exists, the mortgage is considered only the personal estate of the mortgagee, and, as such, passes at his death to his executor and not to his heir. Still, though the mortgagee's interest is thus reduced from the dignity of an estate to that of a mere security, he is not divested of his right to the possession subject to the duty of accounting for the rents and profits, and he may, after entry and notice to the mortgageor's tenants, receive the rents himself. In such a case the mortgage is treated as if it had no existence until actually enforced by the mortgagee. So that whether the lease was made prior or subsequent to the mortgage, the tenant must pay his rents to his landlord the mortgageor, until notice or demand by the mortgagee. If the mortgagee enter into actual possession of the estate, he will be held accountable, as bailiff or steward of the mortgageor, for the net rents and profits. These are to be ascertained after deducting from the receipts the cost of ordinary repairs, taxes, and other expenses of this character. The mortgagee will be held to account for the utmost value the estate would have produced with ordinary care. It is the usual custom in this country to allow the mortgagee a reasonable compensation as trustee of the mortgageor for his trouble in managing the estate. The amount of it and other items of allowance are generally prescribed by statute. In conformity with the American principle of giving complete publicity to titles of real property, the mortgagee's rights depend very materially upon the registration of his mortgage. In some of the states the deed is inoperative until recorded, except between the parties and their heirs; and it is the general rule that if not recorded, it is void as against a subsequent purchaser or mortgagee, for valuable consideration, who was without notice of the prior encumbrance, and whose conveyance is first duly recorded. But, in this respect, the particular statutory provisions of each state must be consulted. —The mortgage being regarded both at law and in equity as merely a security for the debt, payment of that relieves the estate of its encumbrance; and the mortgage may also be extinguished by an express release from the mortgagee, as also by a tender and refusal of the money, though the debt remains due. A mere change of the securities, as giving a new note for the old one, so long as the same debt remains, does not discharge the mortgage, though it would be otherwise if the facts of the case disclose the evident intention of the parties that the substitution should operate as payment of the debt. If the mortgageor have died leaving real and personal estate, without charging either with the payment of his debt, his personal estate will be first applied to this purpose, because that is the fund which was increased by the money borrowed. When this fails, the proceeds of lands devised for the payment of debts will be applied. If a wife join with her husband in

a mortgage of her own estate, and the money be used by the husband for his own benefit, it is the wife's right to have his personal estate devoted to the extinguishment of the mortgage. — If the mortgageor remain in possession, payment before breach of the condition will revert the estate in him at once. If the payment be made, though after a breach, it is a good defence to the mortgagee's action at law to recover possession of the estate; and although it has been said that in such a case it is requisite to revert the estate in the mortgageor by a formal reconveyance, the rule of law does not make this necessary. The reason of this, on the best authorities, is, that it is the practice in most of the states to insert in the mortgage deed a proviso that on the payment of the money at a time mentioned, the deed shall be wholly void. Now the time of performance is not of the essence of the contract, but may be waived by parole; and therefore the acceptance of the money after the day amounts to a waiver of the time, and is a substantial performance of the condition. — Many of the state statutes contain explicit provisions respecting the discharge of mortgages upon the record. From the jealous care with which the debtor's rights are protected by the law, no terms made by the mortgagee are suffered to abridge those rights. This disposition of the courts is based upon the rule, which has long prevailed, that what was once a mortgage must always continue to be a mortgage. It has been therefore held that the heir of a mortgageor might redeem, though the right to do so was expressly limited to the lifetime of the mortgageor himself. So an assignee has been permitted to redeem, though it was agreed that only the heirs male of the mortgageor's body should enjoy the right. It has even been said that a condition would be void which provides that if a mortgageor fail to pay on the day fixed, the payment of a further sum by the mortgagee shall render him absolute owner. — All parties legally interested in the estate in privity of title with the mortgageor may have the benefit of his right in order to the enforcement of their claims. Thus his heirs, devisees, assignees, judgment creditors, and remainder men may assert this right. If any one interested will redeem, he must pay the whole debt; if his interest were only partial, he is entitled to contribution from the rest. Whether this right to redeem the land by payment of the debt be subject to execution, has been variously held in different states. At common law it is only a strictly legal estate which can be so levied upon. With an apparent contradiction in terms, this right of redemption has been called the legal estate, and in conformity with this conception of the right, it has been sometimes held at common law to be subject to execution. In almost all the states it has been rendered so by express legislation. The period within which the right of redemption must be exercised is generally fixed by statute. — Foreclosure is the process by which a mortgagee himself acquires, or by sale transfers

to another, an absolute title in property, of which he has until now been only the conditional owner. Various methods of pursuing the remedy are prescribed by state statutes. The process is instituted in some states by bill in chancery calling on the mortgageor presently to redeem or be for ever foreclosed. The court may sometimes order a strict foreclosure, as it is called; the effect of which is to vest the estate absolutely in the mortgagee as purchaser in default of payment. In such a case, the foreclosure has been sometimes regarded as satisfaction of the debt, and the mortgagee's remedy as exhausted. But generally he may have his action at law for the difference between the value of the property and the larger amount of his debt. Usually upon petition the court issues its decree, ordering payment within a fixed time, and on default of it a sale by a master, the satisfaction of the debt, and the payment of the surplus if any to the mortgageor. Another mode of foreclosure is by a sale in virtue of a power to sell contained in the mortgage deed, which has already been considered. A third mode is that by entry; and this may be either peaceably in the presence of witnesses, or under certain forms of law required by statutes. If this process is adopted as preliminary to a strict foreclosure, the mortgageor will be allowed a liberal time after the entry for payment of his debt. The mortgagee may, generally, enforce all his securities until his claim is satisfied, proceeding as well against the person of the mortgageor as against the land.—A glance at equitable mortgages will complete this sketch of the doctrine of mortgages of real property. A legal mortgage, as has been seen, is made by a transfer of the legal estate to the mortgagee by a regular conveyance. In England the deposit of the title deeds of an estate with a creditor will create what is called an equitable mortgage. The deposit, it is said, is evidence of an agreement to give a mortgage, and this is enforced by giving the creditor an equitable lien. This doctrine is however quite foreign to our law. But in the United States as well as in England, the courts recognize what is familiarly known as the vendor's equitable lien for purchase money; that is to say, when an owner of real estate sells and conveys it without receiving payment of the price, he retains a lien upon the property for so much of the money as remains unpaid. The principle is now generally adopted in our law, but has been rejected in several states. Its admission has been contested with the same arguments which were successfully opposed to the doctrine of an equitable mortgage by a deposit of title deeds, namely, its inconsistency with that publicity which is so characteristic a feature of the American law of real property; for such a lien is not within the usual registration acts and need not be recorded. It will not however be permitted to prejudice the rights of creditors holding under a *bona fide* mortgage, grant, or other conveyance from the vendee, nor against

a subsequent purchaser without notice. Other cases of equitable mortgages are those in which absolute conveyances have been made, but mortgage only was intended. So purchasers at a sheriff's sale under contract with the debtor that he may redeem will be regarded in equity only as mortgagees. Yet another equitable mortgage, that by judgment or final decree, is treated in the article LIEN.—The doctrine of mortgages of personal property is quite as extensive as that already considered. It will not be possible to enter into its details, but a few observations on some of its prominent principles will conclude our review of the doctrine of mortgage. Many of the rules applicable to mortgages of real property are involved also in those of personal property, but the difference in the subject introduces some differences into the law. Any personal property, and any profits arising out of personal chattels, may be the subjects of mortgage. But the articles must be such that they are capable of being specifically designated and identified by written description. The mortgagee has the legal title subject to be defeated by redemption; and, unless otherwise agreed, the right to the immediate possession. As between the parties, the mortgage is valid without a change of possession; but as to subsequent purchasers and creditors, the continued possession by the mortgageor is *prima facie* but not conclusive evidence of fraud; the burden of proof rests on the mortgagee to explain the transaction, and it is for the jury to decide upon the facts. The mortgage must be generally recorded upon a public register; but a full actual notice, such a notice, says the court in Massachusetts, as would have been given by the instrument of mortgage, may preclude a subsequent purchaser or creditor from availing himself of the omission of registration. Under the usual statutory provisions the mortgage must be recorded in the town where the mortgageor lives. In these mortgages the property passes so completely to the creditor that, unlike the equity of redemption in mortgages of real property, it cannot be seized on execution or attached as the property of the mortgageor. This rule is however modified by statute in some of the states. As to assignment and extinguishment of the mortgage by payment, the same general principles apply as to mortgages of real property. The same remark may be made of the distinction between mortgages and conditional sales. The legal doctrine respecting the mortgagee's interest being strictly maintained, a failure to pay the debt at the time appointed creates in him an absolute title, unless where the statutes of the state in which the transaction takes place provide an equity of redemption. In other cases, however, this right may be given by courts having equitable powers.

MORTIER, ÉDOUARD ADOLPHE CARRÉ JOSEPH, duke of Treviso, a French soldier, killed at Oateau Cambrésis in 1768, killed in Paris July 28, 1835. He enlisted as a volunteer in 1791, was elected captain by his fellow soldiers.

served under Dumouriez, and witnessed the battles of Jemmapes and Neerwinden. Promoted to be adjutant-general for bravery at Hondshoote, in Sept. 1793, he was wounded at Maubeuge, but participated actively in the operations under Jourdan that ended in the victory of Fleurus, June 26, 1794. In 1795 he distinguished himself under Marceau, then again under Jourdan at Altenkirchen, June 4, 1796, and was made brigadier-general. In this capacity he served in 1799 on the Danube, and afterward in Switzerland under Masséna. After the 18th Brumaire, Bonaparte made him commander of the 15th and 16th military districts, sent him to Hanover, which he conquered in 1803, put him at the head of the artillery of the consular guard, and in 1804 chose him one of the 18 marshals of the empire. In 1805 he led a division of the army in the campaign against Austria; subdued Hesse-Cassel and Hamburg in 1806; worsted the Swedes in several encounters, and occupied Pomerania with the exception of Stralsund. In 1807 he assisted in the campaign against Prussia, fought at Friedland, and received the title of duke of Treviso. As commander of the 5th corps of the army in Spain, he participated in the siege of Saragossa, won a brilliant victory at Ocaña, Nov. 19, 1809, laid siege to Cadiz, and defeated the Spaniards at Gebora in 1811. In the expedition against Russia in 1812, he commanded the junior imperial guard, and behaved with firmness during the disastrous retreat from Moscow. He figured in nearly all the battles that were fought in 1813; and on March 30, 1814, with the duke of Ragusa, he contributed to the defence of Paris. Having adhered to the Bourbons, he was named peer of France during the first restoration, but joined Napoleon on his return from Elba. On the second restoration, his refusal to sit among the judges of Marshal Ney lost him his peerage. In 1816 he was elected to the chamber of deputies, and 8 years later restored to his seat in the upper chamber; he now voted with the liberal party, and welcomed the revolution of July, 1830. He was ambassador to Russia, and prime minister in 1834, with the portfolio of the war department. He was killed by Fieschi's "infernal machine," while on horseback by the side of Louis Philippe.

MORTIFICATION. See **GANGRENE**.

MORTIMER, ROGER, baron of Wigmore, earl of March, the favorite of Queen Isabella of England, executed at Smithfield, Nov. 29, 1330. He had been convicted of treason in the reign of Edward II. and pardoned; but notwithstanding the king's clemency he took part in the rebellion of the earl of Lancaster, and was made prisoner at Boroughbridge in 1322. His life was again spared, and having escaped from the tower, where he was confined, he went to France and entered the service of Charles of Valois. At Paris in 1325 he met Queen Isabella, who had been sent thither by Edward to negotiate a treaty. Fascinated by his pleasing address, the queen was soon known to be living in guilty

intimacy with the exile, and, having secured the person of her young son, began to mature plans with Mortimer and the other leaders of the barons for getting forcible possession of the kingdom. Mortimer went with her to England in 1326. The insurgents were soon in arms to welcome the invaders; the king was deposed, and his son Edward III. was proclaimed in his stead, and for some years Isabella and her paramour governed the realm in the name of the young prince. A council of regency had been appointed, but Mortimer superseded them all. He procured the death of the dethroned monarch in his prison, and obtained the title of earl of March and valuable confiscated estates. The scandal of his life however was denounced from the pulpit; the nobles wearied of his arrogance, and Edward finally resolved to take the sceptre into his own hands. While the queen and Mortimer were lodged in Nottingham castle during the session of parliament at that town, the king and Lord Montacute with attendants entered by night through a subterranean passage, and, despite the cries of Isabella and the struggles of the guards, carried off the earl. The king summoned a new parliament to meet him at Westminster, and on Nov. 26 Mortimer was condemned by this parliament to be drawn and hanged as a traitor.

MORTMAIN (Fr. *mort*, dead, and *main*, hand; Lat. *mortua manus*). Under the system of feudal tenures, the lords of estates enjoyed certain privileges on the death or change of their vassals. When the tenant died, leaving only an infant heir, the lord resumed the fee and retained it during the heir's minority, in order to maintain, out of its rents and profits, a person capable of rendering the services due for the lands. This was the lord's wardship. Marriage, in the sense of the feudal law, consisted in his right to exact a price for consenting to the marriage of his ward. Relief was another incident of feudal tenure. It was a fine or composition, paid by the heir, for the privilege of succeeding to the estate, which had revested in the lord on the death of his immediate grantor. These and similar profits accrued to the lords on the death of their feudatories. It is the distinctive quality of a corporation that it never dies, and lands held by such bodies produced none of these feudal fruits; but, in the language of Lord Coke, "the lands were said to come to dead hands as to the lords." The mischief had existed even before the conquest. Within two centuries after it, says Blackstone, the busy acquisition of landed estates, by the ecclesiastical corporations, had diminished perceptibly the feudal services ordained for the defence of the realm; the circulation of property from man to man began to stagnate, and the lords were curtailed of their wardships, reliefs, escheats, and the like fruits of their seigniories. The evil attracted the attention of the legislature, and it began to impose restraints on the capacity of corporations aggregate to acquire lands. The earliest of the laws made with this

intent is contained in Magna Charta. The 36th chapter of that instrument declares that "it shall not be lawful for any one to give his lands to any religious house, and to take the same land again to hold of the same house, &c., upon pain that the gift shall be void and the land shall accrue to the lord of the fee." This act destroyed the power to take by gift; for this mode had been adopted by the ecclesiastics to evade the necessity of asking the king's license, which they must by the existing laws have done if they took the lands by purchase. The religious houses next attempted to accomplish their object by buying lands that were *bona fide* holden of themselves, as lords of the fee, or by taking long leases of the desired estates. This is the origin of those terms for 1,000 years or more, sometimes met with in conveyances. This evasion of forfeiture produced the statute *de religiosis* (7 Edward I.), which provides that "no persons, religious or other whatsoever, should buy or sell any lands or tenements, or under the color of any gift or lease or any other title whatsoever receive the same, or by any other craft shall appropriate lands in any wise to come into mortmain, upon pain of forfeiture, at the election of the lords of the fee." But their shrewd lawyers contrived still to relieve the clergy from the embarrassments of these acts. They observed that the statutes thus far extended only to gifts and conveyances between the parties. They invented now, what afterward became one of the most approved assurances in the English conveyancing, namely, a recovery; that is, feigning title to the land which was intended to be conveyed, they brought an action to recover it. By collusion with the tenant no defence was made, and it was the necessary legal consequence that the land was adjudged to the demandants. This contrivance was defeated by the statute of Westminster the second, 18 Edward I. Incapacitated now to take either by gift, purchase, lease, or recovery, and despairing of holding any legal estate in lands, the ecclesiastics resorted to the distinction, familiar to the Roman law, between the right to the rents and profits of land and the right of property in the land itself. They therefore procured a conveyance to a third person and his heirs, with the understanding that the religious houses and their successors should have the beneficial enjoyment of them. This usufructuary interest, as distinguished from the legal ownership, was denominated the use, and founded the whole doctrine of uses and trusts in the present law. Once more the legislature interposed, and by the statute 15 Richard II. declared that no conveyance of lands or other possessions should be made to the use or profit of any spiritual persons, without the license of the king and the mesne lords, upon pain of forfeiture. It will be seen, that though these statutes of mortmain were generally directed against the ecclesiastical corporations, yet civil corporations were equally capable of the mischiefs which they contemplated. In-

deed, they are within the letter of the acts 7 Edward I. and 15 Richard II. The effect of these statutes was to make all lands conveyed in mortmain forfeitable, if the lords or the king elected. But a waiver of this right of forfeiture was always a sufficient license to corporations to hold lands. In process of time, as the mesne seigniories declined, and the rights of intermediate lords could be hardly traced, the license of the king as lord paramount was esteemed sufficient. It was therefore provided by the statute 7 and 8 William III. c. 97, that for the future the crown might, in its discretion, grant a license to take or alien in mortmain, of whomsoever the estates might be holden. The act 9 George II. is now the leading English statute of mortmain. It forbids the gift of money or lands to charitable uses, except by deed operating immediately, and without power of revocation, formally executed and enrolled in chancery at least 6 months before the donor's death. In favor of churches, colleges, and hospitals, some modifications of the statutes have been admitted, but a detail of these is unnecessary.—In the United States, with one exception only, the English mortmain laws have been neither adopted nor recognized. In Pennsylvania they are in force. In that state consequently all dedication of lands to pious uses by deed or will, or grants to other corporations, without statutory license, are void, and subject to forfeiture. These laws apply also to lands held in Pennsylvania by foreign corporations. In the other states the only check to the acquisition of lands by corporate bodies, consists in the special restrictions imposed upon them by their charters of incorporation.

MORTON, JAMES DOUGLAS, earl of, regent of Scotland, born in Dalkeith in 1530, executed in Edinburgh, June 8, 1581. He was a younger son of the great family of Angus, but in 1558 succeeded to the estates and title of his father-in-law, the third earl of Morton. Although a friend to Henry VIII. in his designs upon Scotland, and favorably disposed to the reformation, and even one of the original lords of the congregation in 1557, he took at first no very active part against Queen Mary. In 1561 he became privy councillor, and in the beginning of 1563 was appointed lord high chancellor. In consequence, however, of his participation in the murder of Rizzio, he was compelled to fly to England, but through the agency of Bothwell was shortly after pardoned. Although coadjutant of the plot to destroy Darnley, he appears to have had no hand in its execution. After the forced abdication of Mary which followed the death of Darnley, and the coronation of her infant son, Morton was reinstated in his office of lord chancellor. He supported the interests of the earl of Murray, the regent, against those of the queen; and to him is especially due the result of the battle of Langside, in consequence of which Mary determined to fly to England. In the violent contentions which divided Scotland after the assassination of Murray, Morton

became the real head of the Protestant party, and was a prominent leader of that portion of the people who espoused the king's cause as opposed to the queen's. The earl of Mar, who had succeeded the earl of Lennox as regent, having died in Oct. 1572, Morton was elected regent in his stead on Nov. 24. Henceforth he ruled Scotland with great rigor, and thereby rendered himself odious. He resigned Sept. 12, 1577, but soon managed to regain his authority. Through the agency of the new favorite of the king, Capt. Stewart, he was unexpectedly brought to trial for having been engaged in the murder of Darnley. He was found guilty of high treason, and was decapitated by an instrument called the maiden, which he himself is said to have introduced into Scotland.

MORTON, JOHN, one of the signers of the declaration of independence, born in Ridley, Chester (now Delaware) co., Penn., in 1724, died in April, 1777. About 1764 he was elected to the general assembly of Pennsylvania, of which he became a conspicuous member, serving for several sessions as speaker. He was a member of the stamp act congress, which met in New York in 1765. About 1767 he became sheriff of his county, and shortly after was appointed one of the judges of the supreme court of Pennsylvania. In 1774 he was made a delegate to the first congress, and was reelected 4 times in succession. While in that position, he signalized himself by giving the casting vote of Pennsylvania in favor of the declaration of independence, the 4 other delegates present from that state being equally divided as to the measure.

MORTON, NATHANIEL, secretary of Plymouth colony, Mass., born in England in 1612, died in Plymouth, June 28, 1685. He came to America with his father in July, 1623, and in 1645 was appointed clerk or secretary of the colony court, which office he held until his death. His principal work was "New England's Memorial, or a brief Relation of the most remarkable and memorable Passages of the Providence of God, manifested to the Planters in New England," compiled chiefly from the manuscripts of his uncle William Bradford, and the journals of Edward Winslow, and including the period from 1620 to 1646 (1669; 2d ed., 1721; 5th ed., with notes by Judge Davis, 1826; 6th ed., with notes by the Congregational board, 1855). In 1680 he wrote a brief ecclesiastical history of the Plymouth church in the records of the church.

MORTON, SAMUEL GEORGE, M.D., an American physician, born in Philadelphia, Jan. 26, 1799, died there, May 15, 1851. His father, George Morton, was a native of Clonmel, Ireland, but emigrated early in life to America, where he died in 1799, leaving a considerable family, which found a home among the Friends or Quakers of Westchester co., New York, to whom Dr. Morton was indebted for his early education. In 1814 he was sent to Burlington, N. J., to a school under the direction of the society of Friends, where he spent a year. In the summer of 1815, in the 17th year of his age, he

entered as an apprentice in a merchant's counting house, where he found his position very irksome. In the autumn of 1818 he obtained a copy of Dr. Rush's "Introductory Lectures on Medicine," which he read with such delight that he definitively resolved to follow the medical profession. Accordingly, after the necessary studies, he was graduated as M.D. in 1820. In April, 1820, he was elected a member of the academy of natural sciences of Philadelphia. He shortly afterward embarked for Europe, and on Oct. 20 entered the university of Edinburgh, where, having meantime gone through a course of study in Paris, he was graduated in 1823. In June, 1824, he returned to Philadelphia, and established himself as a physician, but his success was not rapid. Meanwhile he contributed many papers, on a wide range of subjects, to the "Transactions" of the academy, the "Medical and Physiological Journal," Silliman's "Journal," and the "Transactions" of the American philosophical society. These papers evinced a gradual tendency to physiological studies, particularly in the department of craniology; he also devoted himself to making a collection of crania. In 1834 he made a voyage to the West Indies, where he studied the diversity of races and the relations resulting from their contact. In Sept. 1839, he was elected professor of anatomy in the Pennsylvania medical college, which position he resigned in 1843. In 1839 he published his large work, "Crania Americana," upon which his scientific reputation mainly rests. This work was founded on his own collection of skulls, laboriously got together, at heavy cost, without aid from government or societies. As far back as 1840 it was by far the largest museum of comparative craniology in existence, embracing, carefully measured and classified, 867 human skulls, from widely separated regions of the earth, 253 crania of mammals, 267 of birds, and 81 of reptiles and fishes, or a total of 1,468 specimina. The sum of his investigations, as bearing specially on the American aborigines or Indians, was embodied in the work referred to ("Crania Americana, or a Comparative View of the Skulls of various Aboriginal Nations of North and South America; to which is prefixed an Essay on the Varieties of the Human Species; illustrated by 78 plates and a colored map," folio, Philadelphia and London, 1839). Prof. Silliman pronounced it "the most important, extensive, and valuable contribution to the natural history of man which has yet appeared on the American continent." This work was followed by another, less voluminous but scarcely less important, entitled "Crania Egyptiaca, or Observations on Egyptian Ethnography, derived from History and the Monuments," with numerous plates and illustrations (4to., 1844). It was based principally on a collection of 98 heads obtained for him by his friend and disciple, George R. Gliddon, from the tombs and catacombs of Egypt. Following close on these more elaborate publications were others less extensive and formal, which embraced con-

clusions rather than demonstrations, on some of the most interesting questions of physiology and ethnology. Among these were "Observations on the Ethnology and Archæology of the American Aborigines" (Silliman's "Journal," vol. ii., 2d series, 1846), and an "Essay on Hybridity in Plants and Animals, considered in reference to the question of the Unity of the Human Species" (*ib.*, vol. iii., 1847). In 1849 he published "An illustrated System of Human Anatomy, Special, General, and Microscopic." Just before the publication of this work, in Dec. 1848, he was attacked by pleuro-pneumonia, from which he recovered with physical powers much impaired. On May 10, 1851, however, his system gave way, and after 5 days spent in arranging his business and family affairs he calmly died.

MORTON, WILLIAM THOMAS GREEN, M.D., an American dentist, one of the claimants of the discovery of anæsthetics, born in Charlton, Mass., Aug. 19, 1819. His youth was passed upon his father's farm. Going to Boston at the age of 17, he spent some months in a large publishing house, and from this time to his majority he alternated between the counter and the school room. With no taste and little talent for trade, his mercantile career was short and disastrous. In 1840 he commenced the study of dentistry in Baltimore, and 18 months afterward established himself as a dentist in Boston. Among other improvements introduced by him was a new kind of solder by which false teeth are fastened to gold plates, preventing galvanic action. In order to render his work complete, it was desirable that the roots of old teeth should be removed; as this was a tedious and very painful operation, few would submit to it, and there seemed little prospect of the success of the invention unless he could devise means to lessen the pain. He tried stimulants, even to intoxication, opium, and magnetism, but in vain; still the idea possessed his mind that there must be something to produce the desired effect, and he gave himself up seriously to its realization. His limited amount of medical knowledge interfering with the prosecution of his investigations, he entered his name as a medical student in Boston in 1844. About this time the idea was suggested to him in a lecture at the college that sulphuric ether might be used to alleviate pain in his operations; he read such books on chemistry as he could procure, and experimented on animals, but as yet with little success. During his attendance at the medical college and hospital he was obliged to devote all his spare time to his operating rooms and dental laboratory, where he displayed great ingenuity in the mechanical details of his profession, and especially in the manufacture of artificial teeth, which he prosecuted successfully on a large scale. From books and from lectures he learned that sulphuric ether could be inhaled in small quantities with some discomfort, but that in large amount it was dangerous. After experiments on himself, and satisfied of its safety, he administered it to a man on Sept. 30, 1846, producing

unconsciousness, during which a firmly rooted bicuspid tooth was painlessly extracted. After numerous other successful experiments, he communicated their result to Dr. J. C. Warren, and at his request administered the ether, at the Massachusetts general hospital, to a man from whose jaw was removed a vascular tumor on Oct. 16, 1846, the patient remaining unconscious during the operation; from this date the introduction into general surgery of the discovery of ethereal anæsthesia. Like all other great discoveries, however, it met with the bitterest professional opposition; the jealousy of dentists, the fears of physicians, and the scruples of theologians were in many cases arrayed against it, and various persons claimed to have suggested it. In order to protect himself against such opposition, to secure a fair compensation for his expenditure of time and money, and to keep his discovery within the hands of competent persons, Dr. Morton obtained for it a patent, under the name of "letheon," in Nov. 1846, in the United States, and in the following month in England, offering, however, free rights to all charitable institutions in all parts of the country. Notwithstanding his generous offers, government appropriated his discovery to its use without compensation. Upon their first examination of the testimony, some of the Paris academicians at first recognized Dr. Jackson as the discoverer; but the committee of the academy awarded the Monthyon prize of 5,000 francs to be equally divided between him and Dr. Morton. The latter declined to receive this joint award, protested against the decision of the academy, and in 1852 received the large gold medal, the Monthyon prize in medicine and surgery. He underwent an amount of persecution almost unparalleled in the annals of personal enmity, in private and before congress, his business was broken up, and his very house attached by the sheriff for debts; but his indomitable will and the encouragement of firm and powerful friends enabled him ever to maintain his claims to the discovery. Relying upon the impartiality and generosity of congress for remuneration of his labors, he had presented his first memorial in Dec. 1846, upon which the appointed committee did not report. Strengthened by the testimonial inaugurated by the trustees of the Massachusetts general hospital in 1848, which conceded to him the discovery of the power and safety of ether in producing anæsthesia, he made a second application to congress in Jan. 1849; a committee, composed entirely of physicians, heard the evidence on both sides, and reported that he was entitled to the merit of the discovery; but on account of the press of business toward the close of the session and on the eve of a change in the administration, they deemed it undesirable to recommend any pecuniary remuneration. Returning from Washington, he made a brief stay in Baltimore, where he received the regular degree of M.D. from Washington university. In Dec. 1851, he made a third and last appeal to

congress, and his memorial was referred to a select committee; the report of the majority, after a most elaborate investigation, awarded the honor of the discovery to Dr. Morton, and in April, 1852, the majority reported a bill appropriating \$100,000 as a national testimonial for his discovery, on the condition that he should surrender his patent to the government; this bill, on account of the excitement attending the then approaching presidential election, was not acted upon, though warmly approved by several members of the cabinet and urged by members of congress; having at last been brought before the senate as an amendment to the army appropriation bill, it was defeated. In 1853 an amendment to the appropriation bill was offered, granting \$100,000 to the discoverer of practical anæsthesia; after a warm debate it passed the senate, 26 to 23, but failed in the house. In 1854 a similar bill was presented by Mr. Everett, which passed the senate by 24 to 13, but was lost in the house. Thus ended a struggle of 8 years spent in vindicating his claims. In 1854 Dr. Morton attempted to obtain from the executive a recognition of the validity of his patent, supported by the recommendation of 150 members of congress that the right to use his discovery be purchased for the public service, or that the government respect its own patent and discontinue its use; after 2 years' delay the president informed him that whenever it was decided in the courts that the government had violated his patent, it would pay. At this defeat his creditors became importunate, and reduced him and his family to utter poverty; but in the winter of 1856-'7 a plan for a national testimonial was instituted in Boston, encouraged by many of the principal physicians and merchants of that city; in their appeal they give to him the credit of presenting to the world the fact that a safe insensibility can be produced by etheric vapors in the following words: "Nearly the whole of the medical profession of this city, in the midst of whom the discovery was made, together with other bodies of competent persons who have investigated its origin, have, after careful scrutiny, concurred in assigning this merit to Dr. Morton, and public opinion has long since affirmed their verdict." In 1858 a similar appeal was made in New York, signed by the principal medical men of that city, from which the following is an extract: "For this discovery the world is indebted to Dr. William T. G. Morton, of Boston. Whatever may have been the steps preliminary to this remarkable discovery, Dr. Morton's claim to it is established beyond all controversy, and his merit in this respect, with those who have taken the trouble to inform themselves on the subject, can be no longer a question of dispute." In 1860 the medical profession of Philadelphia signed a testimonial of the same character, which says: "We believe the practical originator of anæsthetic inhalation to be Dr. William T. G. Morton, of Boston, Mass. We are convinced that he is the

one who first resorted to ethereal inhalation for the purpose of producing insensibility to pain in a patient while undergoing a surgical operation; and that he is the one who first succeeded in effecting this result. He was, indisputably, the first to urge the anæsthetic properties of the vapor of ether upon the attention of the medical profession, and thus succeeded in establishing the practice of anæsthetic inhalation." In 1858, to save his home from the sheriff's sale for debt, he instituted a suit against a marine hospital surgeon for infringing his patent, as suggested by the president, which was decided in his favor in the U. S. circuit court.—See "Trials of a Public Benefactor," by Dr. Nathan P. Rice (New York, 1859).

MOSAIC (Gr. *μουσαϊκον*, polished, elegant, or well wrought; Lat. *mosaicum*), the representation of a design by the fitting together on a ground of cement of numerous small pieces of stone and glass, of various colors and generally of a cubical form, as stitches of different colors are used in worsted work. Although one of the most mechanical of the fine arts, it is entitled to rank as a style of painting, from the fact that it requires the preparation of a cartoon or colored design as in the case of a fresco or an elaborate oil picture, and no inconsiderable knowledge of art and the science of form, color, and composition on the part of the artist. Dating from a remote period, it has been transmitted through successive eras and schools to the present time, and in modern Italy has been carried to a higher degree of perfection than it attained at periods when it was almost the only species of pictorial art in vogue. Of the mechanical process, the following description of the practice in the establishment at the Vatican in Rome will convey an adequate idea: "The slab upon which the mosaic is made is generally of Travertine or Tibertine stone. In this the workman cuts a certain space, which he encircles with bands or cramps of iron. Upon this hollowed surface mastic or cementing paste is gradually spread as the progress of the work requires it, thus forming the adhesive ground or bed on which the mosaic is laid. The mastic is composed of calcined marble and finely powdered Travertine stone, mixed to the consistence of paste with linseed oil. Into this paste are stuck the *smalti* or small cubes of colored glass which compose the picture, in the same manner as were the colored glass, stone, and marble *sectilia* and *tesserae* of the ancients. The *smalti* are vitrified but opaque, partaking of the nature of stone and glass, or enamels; and are composed of a variety of minerals and materials, colored, for the most part, with different metallic oxides. They are manufactured in Rome in the form of long, slender rods, like wires, of different degrees of thickness, and are cut into pieces of the requisite sizes, from the smallest pin point to an inch. When the mastic has sufficiently indurated (and it acquires in time the hardness of stone), the work is susceptible of a polish like crystal. Care must be taken, how-

ever, that by too high a polish the entire effect of the work is not injured, as innumerable reflected lights in that case would glitter in every part of the picture. When the design is to be seen at a very considerable distance, as in cupolas or flat ceilings, they are generally less elaborately polished, as the inequalities of the surface are the less distinguishable, and the interstices of the work cannot be detected by the spectator." By this process many copies of the large pictures by Raphael, Domenichino, and other old masters in the Vatican have been executed, occupying periods of from 12 to 20 years, and requiring from 10,000 to 15,000 different shades of the primary colors for the purposes of the work. A very splendid specimen, owned by Edward F. Davison of New York, representing the ruins of Paestum, contains over 750,000 pieces of enamel within a space of 5 by 2½ feet, and occupied 5 years in the execution. In 1853 Pope Pius IX. sent to the crystal palace exhibition of New York a mosaic copy of Guercino's "St. John the Baptist," valued at \$60,000, which at a short distance it was impossible to distinguish from a highly finished oil painting. This, however, was a work of small importance in comparison with others preserved in the cathedrals of Europe, in one of which, that of S. Roque in Lisbon, is a chapel dedicated to St. John the Baptist, which contains 8 mosaics estimated to have cost together \$4,000,000. The value in this case was probably greatly enhanced by the employment of precious stones. Two other species of mosaic work are carried on in Tuscany (whence the name, Florentine mosaics), the *pietre dure* and *pietre commesse*, both of which are employed for ornamental purposes, and represent fruit, flowers, birds, &c. The former gives the objects depicted in relief in colored stones. The latter consists of precious stones, as agates, jaspers, lapis lazuli, &c., cut into thin veneer and carefully inlaid.—The employment of mosaics, which have always possessed a certain value, as well from their imperishable nature as from their intrinsic merits as works of art, originated probably among those eastern nations by whom so many of the arts have been transmitted to Europe. The Romans acquired a knowledge of the process from the Greeks, who in turn borrowed it from the Asiatics; and among these three nations it was originally applied as an ornament for pavements, the close imitation of inanimate objects scattered apparently over the floor being the chief aim of the artist. Large historical compositions, of which the mosaic representing the battle of Issus from the Casa del Fauno in Pompeii affords a felicitous example, succeeded; and under the first Roman emperors the art attained a considerable degree of refinement, though still used chiefly as an adornment for pavements. The Romans made it coextensive with their civilization, and from Britain to the Euphrates remains of ancient Roman mosaics have frequently been exhumed. Of the varieties in use among the an-

cients, the principal were the *pavimenta sectilia*, consisting of floors formed of pieces of stone of different colors, cut geometrically and cemented together; the *pavimenta tessellata*, or floors inlaid with small cubes of stone forming a colored design; the *opus vermiculatum*; and the *opus musivum*, in which colored cubes of clay or glass of every conceivable tint, set up very much as types are by compositors, were employed to produce elaborate finished pictures. The first three were included under the general name *lithostrotum*. With the overthrow of paganism and the establishment of the Christian religion commenced a new and grand era in the history of the art; and mosaics, from being used almost exclusively in pavements, were transferred to the walls and ceilings of sacred edifices. The connecting link between the mosaic pavements of Pompeii and the mosaics of Christian origin is so slight, that Dr. Kugler is "almost tempted to believe that historical mosaic painting of the grander style first started into life in the course of the 4th century, and suddenly took its wide spread." For nearly 1,000 years from this period it was almost exclusively employed for mural decoration, and from its durability, which caused Domenico Ghirlandaio to say that it was the only painting for eternity, has preserved a knowledge of the arts and in some degree of the religious ideas of the middle ages. From the 7th to the 9th century the most important and interesting remains of pictorial art are the mosaics in the churches and the MS. illuminations; and the most ancient representations of the Virgin Mary now remaining are the old mosaics in the churches of Rome, Pisa, and Venice, referred to the latter half of the 5th century.—Christian mosaics admit of two general divisions, the later Roman and the Byzantine style, the materials in use being in general cubes of colored glass, inlaid, in the Roman school, on a ground of blue or white, and in the Byzantine school on a gold ground, although in the latter the *tesserae* are frequently irregular in size and the workmanship coarse. The former style flourished in Italy chiefly in the 5th and 6th centuries, the most splendid specimens of it being found in the churches of Rome and Ravenna. The churches of Sta. Maria Maggiore and of San Vitale in the latter city contain perhaps the finest. When in the 5th century the arts and sciences were driven out of Italy by the distracted state of the country, they found refuge in Byzantium, where about the commencement of the 6th century arose that peculiar style pervading many branches of the fine arts to which the general name of Byzantine has been applied, and which for 5 succeeding centuries had a predominant influence throughout Europe and among many eastern nations. The first and greatest example of it is the celebrated church of St. Sophia, built by Justinian about the middle of the 6th century, and adorned with an almost incalculable wealth of mosaics, of which only a few colossal seraphim and

traces of a figure of the Madonna have escaped the effects of Mohammedan fanaticism. By the middle of the 7th century it gained a foothold in Rome, where the native school of mosaics had lapsed into decay; and subsequently it came into competition with the Lombard, Norman-Byzantine, and Romanesque styles, each of which betrays the influence of the parent Byzantine. The mosaics in the church of St. Mark in Venice, executed between the 11th and 14th centuries, are perhaps the purest specimens of the style in Italy. They cover a surface of many thousand square feet of the upper walls, wagon roofs, and cupolas, and are laid upon a gold ground. Others, in a different style, were executed as late as the 16th century, Titian, Tintoretto, and contemporary masters, in some instances furnishing the cartoons, and the whole are fitly described as "a gigantic work, which even all the wealth of Venice spent 6 centuries in patching together." In the 12th century a new or Romanesque style, founded upon Byzantine traditions, arose in Italy; and early in the 13th century the Italians in northern and central Italy, renouncing their dependence on Greek artists, began to execute mosaic work for themselves according to original conceptions of nature. Andrea Tafi, one of the earliest and most famous of the Italian *mosaicisti*, produced a figure of the Saviour, 14 feet high, which, Vasari says, spread his fame throughout Italy. Contemporary with and immediately succeeding him were Jacopo da Turriz, the Gaddi, Giotto, and others, of whom the last executed the celebrated *navicella*, now in St. Peter's in Rome. Among the latest of the *mosaicisti*, who worked from their own or original designs, were Baldovinetto, Gherardo, and particularly Ghirlandaio, the master of Michel Angelo, and Muziano, who brought the art to great perfection. At the commencement of the 17th century Clement VIII. employed numerous artists to decorate the interior of the dome of St. Peter's with mosaic copies of the works of eminent masters, and each succeeding century has added to the immense wealth in works of art of this description deposited in the church. In the 18th century Peter Paul de Christophoris founded a school for mosaic in Rome, where the art is now practised on a grander scale than in any other part of the world. Among eminent modern *mosaicisti* are Barbieri, director of the government manufactory, Luigi Moglia, Poggioli, Gabrini, and Boschetti, all of whom live in Rome.

MOSASAURUS, a gigantic fossil reptile, so named by Conybeare from its having been first found on the banks of the river Meuse, near Maestricht in Holland, in the upper cretaceous formations of that district. It was referred to the orders of cetaceans and crocodilians, but A. Camper and Cuvier showed from the teeth and the skeleton that its true place was between the monitors and the iguanian lizards. The bones of the head are like those of monitors; the teeth of the jaws are compressed, sharp-edged, sup-

ported on a socket in a shallow furrow, without true roots; there are teeth also on the pterygoid bones, as in the iguanians; there seem to have been 28 teeth in each jaw, with broad base and slightly curved. The head is elongated, and the mouth wide; the vertebræ concavo-convex, 84 from head to tail, the latter having nearly 100; as the articular processes are absent from the middle of the back, it has been inferred that the body possessed greater flexibility than that of the crocodiles; the tail is compressed laterally, and has strong V-shaped bones below, indicating its use as a powerful swimming organ; the ribs have a single head; the humerus short and thick as in the ichthyosaurus, and the limbs probably flattened into fins as in enaliosaurians. It must have been a very active marine carnivorous animal. The best known species, *M. Camperi* (Conyb.), had a head 4 feet long, while that of the largest living monitor is only 5 inches, and the length of the animal must have been 25 feet. When Maestricht was besieged by the French toward the close of the last century, the artillerymen were ordered not to direct their shot to the part of the city which contained this celebrated specimen; after the capture of the place, these bones were sent to Paris. (See Cuvier's *Ossemens fossiles*.) The genus *geosaurus* (Cuv.), found in the calcareous schists of Menheim, came nearer the crocodiles in the pelvis and thigh bones.—See "Proceedings of the Academy of Natural Sciences," pp. 91, 92 (Philadelphia, 1859).

MOSBOURG, COMTE DE. See AGAR, JEAN ANTOINE MICHEL.

MOSCHELES, IGNAZ, a German composer and pianist, of Jewish race, born in Prague, Bohemia, May 30, 1794. He was destined for a mercantile career, but at 8 years of age was allowed to receive musical instruction from Dionysius Weber. In 8 years he became a skilful pianist; and at 14 he was introduced at Vienna to Haydn and Beethoven, and by their advice became the pupil of Albrechtsberger, with whom he made rapid progress. As a pianist he also gained so much in facility of execution as to compete with Hummel, then reputed the first performer in Germany. After an extensive continental tour he arrived in 1820 in England, where he resided during the next 26 years. His reputation as a pianist, at first supreme, has yielded to the claims of Thalberg, Liszt, and others; but probably no musician has so greatly influenced the cultivation in England of the classical music of Bach, Mozart, Beethoven, and kindred composers, or so fully developed a taste for pianoforte music and a knowledge of the resources of the instrument. As a performer of the sonatas and concertos of Beethoven he is still without a superior. His compositions for the pianoforte are finished specimens of classical music, and his trios, quintets, &c., for the violin and other instruments, evince great theoretical knowledge. In 1846 he became musical professor in the conservatory of Leipzig, where he now resides.

MOSCHI, an ancient people of Asia, S. of the Caucasus, whose territory at the time of Augustus was divided between Colchia, Iberia, and Armenia, and from whom a mountain range extending from the Caucasus to the Anti-Taurus received the name of Moschic mountains. Their name, in early classical writers, frequently appears coupled with that of the Tibareni, and the two tribes are generally identified with the Meshech and Tubal of Scripture. (See **JAPHETH**.)

MOSCHUS, a Greek bucolic poet, who lived about the middle of the 8d century B. C. He was a native of Syracuse, and a pupil or imitator of Bion. There are 4 of his idyls and some small fragments of his lost poems still extant, chiefly in the Doric dialect. The best editions are those of Jacobs (Gotha, 1795), Wakefield (London, 1795), and Manso (Leipsic, 1807).

MOSCOU, a city of Russia, in the government of the same name, situated in the centre of the empire, on the rivers Moskva and Yansa, a small stream, in lat. $55^{\circ} 45' 18''$ N., long. $37^{\circ} 38' 8''$ E., 400 m. by railway S. S. E. from St. Petersburg; pop. of the city in 1856, 368,765; of the government, 1,580,405. Though no longer the sole metropolis, Moscow still shares this dignity with St. Petersburg; it continues to be specially esteemed by the Russians as the place of the coronation of the czars, the favorite residence of many of the nobility, the commercial emporium of central Russia and western Asia, and a principal seat of Russian manufactures. It is the holy or white mother city in the creed of the people, and no czar would dare to omit visiting it at least twice a year, or presenting in the city his eldest son after he has reached majority. No other city in the world presents so picturesque an aspect. The view of its thousand spires, domes, and minarets, with their diversity of form and color, of the fantastic pile of the Kremlin, and of the garden plots and trees intermixed with the houses, presents a strange oriental panorama, while the pagodas, temples, churches, modern palaces and old yellow cottages, Chinese tea houses and French cafés, Turkish bazaars and Russian market places, and the different costumes of the various classes of the population, including Persians, Armenians, Tartars, Circassians, Russians, Poles, and Europeans of all nations, everywhere combine the most striking Asiatic and European characteristics. From the promiscuous mingling in the same locality of palaces and huts, imposing and unassuming places of worship, stately public buildings and modest private residences, Moscow has been fitly described as being at once "beautiful and rich, grotesque and absurd, magnificent and mean." After the conflagration of 1812 a portion of the city was rebuilt in better taste, some of the principal streets were widened, and two concentric circles of boulevards were added; but the greater part of the smaller streets were rebuilt on the old plan, and though Moscow presents now to some extent the improved appearance and attractions of a

modern city, its ancient and unique character has not been essentially changed. The Kremlin, which has been completely repaired since 1811, still rises on an eminence in the heart of the former metropolis, and forms the central nucleus of Moscow. (See **KREMLIN**.) The emperor Nicholas extended the area of the Kremlin, and spent millions of rubles for its embellishment; nevertheless preserving the original architectural character of the great walls, porticos, staircases, and churches.—The diameter of the city from N. to S. is estimated at 8 m., and its circumference at 28 m. It has been justly called a city of magnificent distances, the lowness of the houses, the enormous width of the principal thoroughfares, the large interior courtyards and spacious market places, the immense space filled by the public edifices, by pleasure grounds, fields, upward of 200 ponds or small lakes, and marshes, all combining to give it a great extent in proportion to its population. The Moskva divides the city into two unequal parts, about $\frac{1}{2}$, including the Kremlin in the centre, occupying the northern, and $\frac{1}{2}$ the southern bank. On the latter are the Sparrow hills which run nearly E. and W. and include the whole southern portion of the city. Outside of the boulevard are the private residences, and in the outskirts are the cottages of the poor. Moscow is divided into 5 principal quarters: 1, the Kremlin, with the most magnificent churches, palaces, monasteries, the celebrated bell-towers (see **BELL**, vol. ii. p. 98), treasury, arsenal, house of the holy synod, and other public buildings and monuments; 2, the Kitai Gorod, or Chinese city, E. of the Kremlin, surrounded by a wall with 15 towers and 5 gates, the centre of trade, containing the Riadi, an open space of ground laid out in narrow streets of shops or booths, and the Gostinnoi Dwor, or great bazaar, the greatest mart after Nijni Novgorod, occupied by merchants trading with Siberia, China, Tartary, and almost all other parts of the world; 3, the Beloi Gorod or white town, encircling the Kremlin and Chinese city, and bounded by the river and inner boulevard, containing the palace of the governor and the assembly house, many palaces of the nobility, the university, the foundling hospital, the post office, a celebrated circus or military riding school (560 feet long and 184 wide, the roof being unsupported except by the outer walls), and the French and imperial theatres; 4, the Zemlianoi Gorod (earthen town), so called from the former earthen rampart, now converted into a boulevard planted with trees, containing the depot of the commissariat, the depot for spirits, the commercial school, the imperial philanthropic society, and academy of medicine and surgery; 5, the suburbs or Slobodi, surrounding the Zemlianoi Gorod, and like that part of the city possessing a great variety of fine mansions and houses, and presenting alternately scenes of bustle and animation and village-like places of rural seclusion. Many of the most celebrated hospitals are scattered over the suburbs, as well as churches and

monasteries.—Moscow has nearly 800 churches, chiefly Greek, beside a great number of chapels and religious houses. There are several places of worship for Roman Catholics, Protestants, and Armenians, and in the Turkish mosque in the vicinity of Tartar street service is held on the Sabbath (Friday) of the Tartar population. The most celebrated cathedrals of Moscow are those of the Assumption, the Archangel, St. Michael, and the Annunciation in the Kremlin, and that of St. Basil in the Krasnoi Ploshtschad or Red place between the walls of the Kremlin and the Kitai Gorod. The Petrovskoi cathedral in the Kitai Gorod consists of 21 places of worship joined together. The church of St. Anne in the Zemlianoi Gorod, which has given its name to a monastery, is a fine Gothic building noted for the elegance of the interior. Among the largest religious establishments are the Donskoi and Seminoff monasteries, which have both the outward appearance of fortresses. The convent of the Dewitchii at the end of the Dewitchieipolie or Maiden's field, an extensive place surrounded by 16 towers, where the czars give public banquets on occasion of their coronation, contains the tombs of many Russian princesses and the miraculous Virgin of Smolensk. The charitable institutions of Moscow are remarkable for their magnitude. Among the principal are the Galitzin hospital, Sheremetoff hospital, St. Catharine's hospital, the military hospital, and above all the great foundling hospital. (See *FOUNDLING HOSPITAL*, vol. vii. p. 638.)—At the head of the educational institutions stands the university, the centennial anniversary of which was celebrated in 1859, and which is attended by about 1,000 students. Dependent on it is the gymnasium of Moscow. The theological academy is the most important in Russia. There are also excellent military, medical, veterinary, and mercantile schools. Seminaries for young ladies are numerous, and the number of common schools is increasing. There are a number of extensive public and private libraries, and of societies for the promotion of letters, art, and science. A literary rivalry exists between the savants and litterateurs of Moscow and St. Petersburg, the Moscovitans looking down on the Petersburgians. Moscow is the focus of Panslavism, and Schafarik calls it the Slavic oak with golden leaves. Intellectual activity has made rapid progress in Moscow, as well as in other parts of Russia, since the promulgation of the decree for the consideration of the abolition of serfdom in the beginning of 1858.—Beside the imperial palaces in the Kremlin are the Petrovskoi palace and gardens outside of the St. Petersburg gate, the principal fashionable resort during the summer season, and the palace of the empress Elizabeth; and among the favorite pleasure grounds are the beautiful gardens of the Kremlin and the Galitzin garden on the Sparrow hills, near which is the villa presented to the empress Maria Alexandrovna by Count Orloff. Moscow is the residence of two archbishops, and of the governor-

general of the province (in 1860, Count Strogonoff).—The most important Russian manufactories of woollen cloths, cotton, silks, carpets, jewelry, paper, &c., are in the government and city of Moscow. Their number exceeds 1,200; they employ upward of 120,000 persons, and the articles produced in the government are valued at \$40,000,000. It is an important centre of the internal trade of the empire, which is facilitated by extensive intercommunication with all the ports and cities, and by the St. Petersburg railway, the receipts of which amounted in 1856 to \$5,000,000, $\frac{1}{3}$ for freight and the rest for passengers. The opening of all the ports of China to the commerce of the world, under the stipulations of the late treaties between that government and the western powers, promises to give a great impulse to the silk and tea trades and to the general commercial activity of Moscow. Beside the Riadi and the great bazaar, there are a great number of other market places. The so called winter market presents a remarkable aspect during the winter, when the fish of the White sea and northern lakes, the frozen oxen from the Crimea, Caspian sheep, and deer from the banks of the Irtysh and Yenisei, are piled together. The horse market of Moscow is of great importance, and the city contains also a race course. Industrial exhibitions often take place in the city.—Moscow is said to have been founded in the middle of the 12th century by George Dolgoruki, prince of Kiev. Ivan Danilovitch of Vladimir took the title of grand prince of Moscow in the early part of the 14th century, and from that time it remained the seat of government until the beginning of the 18th, when the administration was transferred by Peter the Great to St. Petersburg. Moscow was plundered by the Lithuanians and the Tartars of Tamerlane in the latter part of the 14th century, and subjected to many vicissitudes in the 15th and 16th. It was nearly consumed by fire in 1536, in 1547, and again in 1571, when the Tartars set fire to the suburbs, a large part of the population perishing on that occasion. During the insurrections caused by the pseudo-Demetrius (1605-'12), when the Poles and Cossacks took the city, it was again partly destroyed. In 1812 it was entered by the French under Murat on Sept. 14, and on the 15th by Napoleon, who took up his residence in the Terema palace in the Kremlin. The city, deserted by its inhabitants, was set on fire by order of the governor, Count Rostoptschin, compelling Napoleon to leave on Oct. 19, and to take his final departure on the 28d, and resulting in the disastrous retreat of the French army. The greater part of the city was then destroyed, notwithstanding the efforts of the French to stay the progress of the flames. It was rebuilt within a few years, and has since fully recovered from the calamity. The railway to St. Petersburg was opened in 1851. In 1856 Moscow presented a scene of great animation and splendor on occasion of the coronation of the present emperor Alexander II. in

the cathedral of the Assumption (Sept. 7). In Aug. 1860, the emperor visited Moscow in order to introduce the tzarewitch, the grand duke Nicholas, to the ancient capital of the empire.

MOSELLE (Germ. *Mosel*; anc. *Mosella*), an affluent of the Rhine, which rises in France, in the S. E. part of the department of Vosges, and flows nearly N. W. to Toul, in the department of Meurthe; thence its course is N. E. till it is joined by the Meurthe, when turning N. it passes through the department of Moselle, out of France, and for over 20 m. forms the boundary between Rhenish Prussia and Dutch Luxemburg. Its course then again changes to the N. E., and so continues through Rhenish Prussia to Coblenz, where it falls into the Rhine. The Moselle is about 820 m. long, more than 180 m. of which is through France. Its chief tributaries are: on the right, the Vologne, Meurthe, Seille, and Sarre; on the left, the Madon, Math, Orne, and Sure. The principal cities on its banks are Metz, Treves, and Coblenz. It is navigable for over 200 m., or from its junction with the Meurthe to its mouth.

MOSELLE, a N. E. department of France, bounded N. by Belgium, Luxemburg, and Rhenish Prussia, E. by Bavaria, S. by the departments of Bas-Rhin and Meurthe, and W. by that of Menne; area, 2,078 sq. m.; pop. in 1856, 451,152. The surface is in general uneven, but none of the hills are more than 650 feet high, and they are covered from base to summit with vineyards, fruit trees, or forests. The most important minerals are iron, copper, lead, building stone, gypsum, and potters' earth. Linen, muslin, canvas, woollen and cotton stuffs, &c., are manufactured. Capital, Metz. Chief towns, Thionville, Briey, and Sarreguemines.

MOSELLE WINES are produced in the above described department and in the neighboring districts of Luxemburg, Liège, and Lorraine. They are renowned for their pure taste and fine flavor, but are rather light. Both red and white wines are included under the name.

MOSEN, JULIUS, a German poet, born in Marieney, Saxony, July 8, 1808. His father was a schoolmaster; the son studied jurisprudence at Jena and Leipzig. After filling some inferior judicial stations in the provinces, he removed to Dresden, where he practised his profession. His first poem, *Lied vom Ritter Wasa* (1831), was followed in 1838 by *Ahasver*. His reputation was more firmly established by his *Andreas Hofer* and other poems, which appeared in 1836 under the title of *Gedichte*. He has since published a series of fanciful works (*Novellen*, 1837; *Die Bilder im Moose*, 1846, &c.). He is also known as a dramatist by his *Cola Rienzi*, *Otto III.*, and other tragedies, collected in 1842, and by his more recent plays *Johann von Oestreich*, the comedy entitled *Die Wette*, and other dramatic productions.

MOSER, GEORGE MICHAEL, an English enameller and gold chaser, born in Schaffhausen, Switzerland, in 1704, died in England in 1788. According to Sir Joshua Reynolds, he excelled

in his profession, had a universal knowledge in all branches of painting and sculpture, and "may truly be said in every sense to have been the father of the present race of artists." He was an original member of the royal academy, and for many years keeper of that institution, in which capacity he instructed the students in drawing and modelling from the antique.—MARY (LLOYD), daughter of the preceding, died in 1819 at an advanced age. She was distinguished as a flower painter, and was the only woman, with the exception of Angelica Kauffmann, ever a member of the royal academy.

MOSER, JOHANN JAKOB, a German jurist, born in Stuttgart, Jan. 18, 1701, died there, Sept. 30, 1785. He was educated at the university of Tübingen, where at the age of 19 he was appointed teacher, and in 1727 professor of law. In 1736 he was made director of the university of Frankfort-on-the-Oder, but this office he abandoned in 1739. In 1749 he founded at Hanau an academy for the instruction of young nobles in political science. In 1759 he was sentenced to 5 years' imprisonment in the fortress of Hohentwiel for having memorialized the duke on the subject of the rights of the estates. He was the first to give a systematic account of European international law. A catalogue of his works, which number nearly 500, is given by Menzel. His principal work is *Deutsches Staatsrecht* (50 vols., Nuremberg, 1737-'54).—FRIEDRICH KARL VON, a German statesman and publicist, son of the preceding, born in Stuttgart, Dec. 18, 1723, died in Ludwigsburg in 1798. He was for many years imperial councillor at the court of Vienna, and afterward a member of the administration of Hesse-Darmstadt. His work entitled *Der Herr und der Diener* (1759), exposing administrative abuses, created a great sensation. Although he was opposed by Lessing and his friends on account of his pietism, this work was warmly defended in Nicolai's "Letters upon Literature," as calculated to promote the political regeneration of the country. Herder, however, says of it: "The minister too obviously dictates, the philosopher has not time enough to digest, and the writer not leisure enough himself to write and to arrange." He exerted a still greater influence by means of the *Patriotisches Archiv*, which he edited from 1754 to 1790, and which for two years was followed by the *Neues Patriotisches Archiv*. He also wrote extensively on public and international laws, and is the author of a *Geschichte der Wenden* (Zürich, 1798), and of *Luther's Fürsten-Spiegel* (new ed., Frankfort, 1834).

MOSER, JUSTUS, a German statesman and author, born in Osnabrück, Dec. 14, 1730, died there, Jan. 8, 1794. He studied jurisprudence at Jena and Göttingen, and became attorney-general in 1747; and for 20 years during the minority of the duke Frederic of York. He came into possession of Osnabrück in 1760, and was the principal adviser of the regent. From 1762 to 1768 he officiated as a magistrate in

criminal court, and afterward until his death as one of the superior officers of justice. His services were as disinterested as they were important. In his writings he often presented his ideas in a humorous garb suited to the tastes of the people. One of his most celebrated humorous works is his *Harlekin*, directed against pedants and hypocrites of all kinds. In his work on the German language and literature he attacks the Gallomania and infidelity of Frederic the Great; and in a letter addressed to Jean Jacques Rousseau he opposes the theories of that philosopher. He believed in the necessity of positive religion for the people, and regarded an aristocratic and paternal administration as the best form of government. His most important contribution to literature is his "History of Osnabrück" (2 vols., 1768; 2d and improved ed., 1780; 3d ed., 1820; a 3d vol. published from his literary remains by Herbut von Bar, 1824). His most celebrated short essays, which originally appeared from 1766 to 1782 in the Osnabrück *Intelligenzblätter*, and were afterward published under the title of *Patriotische Phantasien* (Osnabrück, 1775-'86; 3d ed. prepared by his daughter in 4 vols., Berlin, 1804), relate to local subjects, and are to this day calculated to enlighten the mind and improve the character of German officials. A complete edition of his works was published by B. R. Abeken (10 vols., Berlin, 1842-'3).

MOSES. See HEBREWS, vol. ix. pp. 28-30.

MOSHEIM, JOHANN LORENZ VON, a German ecclesiastical historian, born in Lübeck, Oct. 9, 1694, died in Göttingen, Sept. 9, 1755. He was educated at the gymnasium of Lübeck and the university of Kiel, where he became professor of philosophy. In 1725 he accepted the chair of theology in the university of Helmstedt, and remained there till 1747, when he removed to Göttingen, on being appointed divinity professor and chancellor of that university, where he continued till his death. Mosheim was equally eminent as a scholar, lecturer, and preacher. He was the author of over 160 works, the principal of which are: *Institutiones Historiæ Ecclesiasticæ, Antiquioris et Recentioris* (Helmstedt, 1726); and *De Rebus Christianorum ante Constantinum Magnum Commentarii* (Helmstedt, 1758). These works have been translated into German and English. The best English translation is by James Murdock, D.D., "Institutes of Ecclesiastical History" (3 vols. 8vo., New York, 1832; many times reprinted); and "Commentaries on the Affairs of the Christians before Constantine" (2 vols. 8vo., New York, 1855).

MOSKVA, BATTLE OF THE. See BORODINO.

MOSLEM. See MUSSULMAN.

MOSQUE (Arab. *mesjid*, "place of prayer"), a Mohammedan temple or house of worship. The first mosque was erected by Mohammed himself at Medina, part of the work being done by his own hands. The place chosen for the site was a graveyard shaded by date trees, and the prophet was guided in his choice by the

favorable omen of his camel having knelt opposite to this place on his public entry into the city. The edifice was square in form and simple in structure, the walls of earth and brick, and the roof supported by the trunks of palm trees and thatched with palm leaves. It was about 100 ells square, and had 3 doors. A part of the building was assigned as a habitation to the poor among the faithful who had no other homes. In this mosque Mohammed was buried; and though the original edifice was long ago replaced by a larger and more sumptuous structure, the temple still bears the name of *mesjid al nabi*, "the mosque of the prophet," and has ever since served as a model for the construction of Mohammedan places of worship. Everywhere the mosque is substantially the same in plan, though differing in detail in some countries, as modified by national taste. What in Arabia was simple and elegant became highly ornate in Spain, florid in Turkey, and effeminate in India. It was in the reign of the caliph El Walid, toward the end of the 1st century of the Hegira, that the cupola and the minaret were added to the mosque, and the Saracenic style of architecture introduced throughout the Moslem world. The mosque of the prophet at Medina, the great mosque at Mecca, and the mosque of Omar at Jerusalem, are considered peculiarly holy, and are among the finest extant specimens of Moslem architecture. Cairo has nearly 300 mosques, the chief of which, that of Sultan Hassan, is a majestic edifice in the purest style. The Jumna Mesjid or great mosque at Delhi, built by the emperor Shahjehan about the middle of the 17th century, is however generally considered the noblest building ever erected for Mohammedan worship. The principal mosque of Constantinople was originally the Christian church of St. Sophia, built by the emperor Justinian in the 6th century. The mosque of Solyman the Magnificent, begun in 1550 and finished in 1555, surpasses St. Sophia in beauty and in taste. Attached to this mosque, as to almost all others, are various endowments for institutions of education, piety, and benevolence. It has an annual revenue of 800,000 piasters.

MOSQUITO. See GNAT.

MOSQUITO SHORE, MOSQUITO COAST, or MOSQUITIA, a portion of the eastern or Atlantic coast of Central America, usually understood among geographers as embracing the shore of the Caribbean sea, from Cape Gracias á Dios to Bluefields lagoon, between lat. 12° and 15° N., a distance of about 200 m. It has been claimed by the British government, in its capacity of protector of the Mosquito Indians, that it embraces the entire coast line of Central America, between Cape Honduras, near the port of Truxillo, lat. 16° N., long. 86° W., and Boca del Toro in Chiriqui lagoon, lat. 9°, long. 82°, a coast line of about 700 m. This coast was discovered by Columbus on his 4th voyage in 1502, and was described by his companions as a very low land, filled with creeks and la-

goons, and thinly inhabited by Indians of an inferior grade, dark in color, and barbarous in their character and habits. Without precious metals, and holding out small attractions to Spanish enterprise, this shore was allowed to remain unoccupied, while the central portions and the Pacific coast of Central America were rapidly reduced and populated. During the swarming of the buccaneers in the sea of the Antilles, about the middle of the 17th century, they made this coast a principal place of resort, and established relations which afterward served as the basis of the alleged British protectorate. Early in the same century a Guinea slave ship was wrecked on the coast near Cape Gracias; the negroes escaped, and, with the runaway slaves or *cimarrones* from the Spanish settlements in the interior, mingled with the natives, and gave them that peculiar semi-African character which the Spaniards have indicated by the term *Sambos-Mosquitos*. In 1740 the English attempted to occupy the shore in sovereignty; and, through the intervention of a Capt. Robert Hodgson, obtained from some of the chiefs a cession of the territory to the British crown. This act was followed by an actual occupation, which constituted one of the issues between England and Spain in the war which was terminated by the treaty of Paris of 1763, by which Great Britain agreed to evacuate not only the Mosquito shore, but "all other places in the territory of Spain in that part of the world." Owing to alleged infractions of this treaty by Great Britain, its provisions were revised and made more explicit by the subsequent treaty of 1783, which stipulated that all the "English settlements on the Spanish continent" should be abandoned "without exception." But on the ground that the Mosquito shore was not a part of the Spanish but of the American continent, relations were kept up with the coast as before. This led to reclamations on the part of Spain, which were only settled by the supplementary treaty of 1786, which provided that "his Britannic majesty's subjects and other colonists, who have enjoyed the protection of England, shall evacuate the country of the Mosquitos, as well as the continent in general, and the islands adjacent without exception." But soon afterward the stirring events of the French revolution and the great continental war drew the attention of both countries from this coast. A number of the old settlers remained there in spite of the treaties, and were joined by certain traders from Jamaica, who together established very intimate relations with the Mosquitos and their chiefs, to whom they gave sounding titles, such as kings, governors, generals, and admirals; and they even invented "a regalia," described by Macgregor as consisting of "a silver gilt crown, a sword, and a sceptre of moderate value." Finally, one of these "kings" was taken to the British establishment of Balize, and there, on April 28, 1825, formally crowned as king of the Mosquito nation. This king was sent back to the coast, but, having exhibited

some indications of independence, was again taken to Balize, where he died, not however until he had affixed his mark to a document previously prepared, and styled a will, in which he made over his kingdom to Col. Macdonald, superintendent of Balize, as regent. Col. Macdonald at once sent some of his subordinates to the coast, who were soon after recognized by the British government as acting in its name; and thus originated the English protectorate over the coast. In 1848 an attempt was made to extend this protectorate not only over the greater part of the Atlantic shore of the country, but inland so as to include fully one half of the states of Honduras, Nicaragua, and Costa Rica. Under pretence that it fell within the territory of the so called Mosquito king (an Indian boy living in the house of the British agent), an English naval force, in Jan. 1848, seized the Nicaraguan port of San Juan at the mouth of the river of the same name. As this port was understood to be the only possible Atlantic terminus for the proposed interoceanic canal through Nicaragua, and as its seizure followed close on the acquisition of California by the United States, which gave the question of communication between the seas for the first time a practical value, the attention of the world became suddenly and strongly directed to the British proceedings on the Mosquito shore. The United States sided openly with the Central American republics in denying the claims of nationality set up on behalf of the Mosquito Indians, and equally the validity of the alleged English protectorate. A diplomatic quarrel was at once raised between the two countries. The *de facto* occupation of the port of San Juan, however, by Americans engaged in opening an interoceanic transit, tended greatly to the settlement of the dispute; and a convention between Great Britain and the United States was proclaimed, July 4, 1850, known as the Clayton-Bulwer convention, in which both parties bind themselves not "to occupy, fortify, colonize, or exercise dominion over the Mosquito shore or any part of Central America." A convention was subsequently agreed upon, in 1856, between Lord Clarendon and the U. S. minister in London, according to which, in Dec. 1859, Great Britain concluded a convention with Honduras for the relinquishment of the Mosquito claims over the territory N. of the river Wanka, with the sole condition of an annuity of \$5,000 a year, for 10 years, to such Mosquito Indians as may be found in the district thus surrendered; and a similar arrangement has been proposed with Nicaragua.—The Mosquitos now retain little pure aboriginal blood, being for the most part mixed Indian and negro. They exist only on the sea coast, or on the creeks and lagoons near the sea, and are fishers rather than hunters or agriculturists. The Valiente, Rama, Cookra, Woolwa, Tonga, and Poyas Indians, who inhabit the interior of the country, although sometimes claimed as Mosquitos, are in fact independent tribes, distinct

in language and habits, and generally hostile to the Mosquitos. The same is true of the Caribs on the sea coast of Honduras. Exclusive of these tribes, the population of the shore does not exceed 1,000 or 1,500. The Mosquitos produce a little tortoise shell and sarsaparilla. They are without any form of religion, but believe in a certain spirit of the water called Le-wire, and an evil spirit named Wulasha, who consumes the bodies of the dead. They have great faith in their *sukias* or sorcerers. They are expert in managing their *pilpans* or canoes, and dexterous with the spear, with which they strike fish and capture turtles. Marriage is a rite unknown, and universal licentiousness has produced diseases among them which, with drunkenness, are rapidly reducing their numbers. Their language is peculiar.—The geography of the Mosquito shore is imperfectly known. It is low, and traversed in every direction by lagoons, which receive the rivers descending from the interior, and frequently overflow and unite with each other, so as to permit inland navigation for a distance of 200 m. along the coast. Back of the lagoon region there are extensive tracts of open savanna, well adapted for the raising of cattle. There are also broad, sandy plains, covered with large pines; and the banks of the rivers are generally lined with mahogany, rosewood, caoutchouc, and other valuable trees. The shore has several very good harbors, and positions capable of easy settlement. The most important of these is Bluefields lagoon, which derives its name from a Dutch pirate, Blanvelt, who established himself there early in the 17th century. It is a considerable body of water, between 80 and 40 m. in length, and completely landlocked. The great river Escondido, rising in the distant departments of Nicaragua, flows into it. On the S. bank of that river is situated the town of Bluefields (pop. 500, including 50 whites), the residence of the Mosquito king. N. of this lagoon 30 m. is Pearl Cay lagoon, of nearly equal size, which receives the waters of the large river Wawashaan. Among the other rivers, the Prinzapulka, Tongla, Brackma, Wava, and Duckwara are the largest. They all have their sources in the mountains of Nicaragua, and until they reach the vicinity of the coast are violent and rapid. Their lower waters abound in the manatee or sea cow. The climate of the shore is moist and hot, but compares favorably in respect of salubrity with the West India islands generally. The greater part of the soil is fertile.—See Squier, "States of Central America;" Waikna, or Adventures on the Mosquito Shore;" Roberts, "Voyages and Excursions on the East Coast of Central America;" Strange-ray, "Sketch of the Mosquito Shore," &c.

MOSSES (*musci*), a large family of cryptogamic plants, having distinct stems, leaves, flower-like reproductive organs, and seed-like bodies, which serve to propagate the species. They are cellular in structure, and bear only a faint resemblance to the higher orders of plants. The

stem of the mosses consists of cells of different forms and sizes, as may be readily seen by a transverse section, where those of the circumference are smaller and polyhedral, while those of the centre are elongated and by a closer arrangement approximate toward a woody texture. The stem, when it rises upward and ends in the organs of reproduction, is said to be determinate, and such a moss is acrocarpous; but when it extends lengthwise and laterally in an indefinite manner, it is said to be indeterminate, and the moss is pleurocarpous, because the reproductive organs are borne upon the side branches. The leaves of mosses usually clothe the stem; but in some species the lower part is bare, or at least only covered with a few leaf-like scales. There are two distinct kinds of leaves: 1, those which grow upon the stem, and are called caulinary; 2, those which surround the reproductive organs, and are called perichæstial. These latter are more closely set than are the others, forming a sort of rosette in the centre of which the reproductive organs are lodged. The leaves of mosses are very simple, and usually consist of a single cellular layer. They easily imbibe moisture, and as suddenly wither. A passing shower will revive the mosses which grow upon the driest rocks, and thus delight the eye with their verdure. The cells of the leaves are comparatively large, but the size differs greatly in different species. Each cell usually contains chlorophyl, though the cells of the *sphagnum* appear to be destitute of this principle. The cells are uniform in size and general shape, excepting those toward the central portion of the leaf, where they assume an elongated form and constitute themselves into a sort of rib, nerve, or vein, which either bifurcates at the base and shortly ceases, or is produced into a single nerve and continues through the greater length of the leaf, or even extends beyond the apex and ends in a sort of point. The cells upon the edges of the leaf are sometimes modified into a border or into serrated processes like teeth. Sometimes several laminae are produced along the midrib or nerve of the leaf, and sometimes granules or bulbules are produced there. Buds or innovations are also to be met with sometimes in the axils, which when separated can become new plants. With regard to the stem, the phyllotaxis or position of the leaves is $\frac{1}{2}$, $\frac{2}{3}$, or $\frac{3}{4}$. Another modification of the leaves is into a sort of covering situated inside of the perichæstial leaves, and consisting of 8 to 6 small leaflets closely adhering together and called the perigone.—The floral or reproductive organs are: 1. The *antheridia*, consisting of cylindrical, pear-shaped, or ellipsoidal stalked sacs containing minute cells of $\frac{1}{100}$ of an inch diameter, in each of which a spiral phytozoon is seen. The antheridia dehisce by irregular openings at their apices, and discharge their contents. Accompanying these are attenuated and abortive organs called *paraphyses*. 2. The *archegonia*, often mixed with paraphyses, arise also from similar small clusters or rosettes of leaves,

and appear in the form of spherical or obovate bodies having an outer envelope (*epigone*) and a central cellular nucleus. They are somewhat longer and considerably more slender than the antheridia, and are filiform except toward the base, where they are tumid, and at the apex, where they are slightly expanded. In the process of growth the central portion increases and rises upward, and at the same time the epigone is ruptured near the base, one portion of it remaining below in the form of a small sheath (*vaginula*), the other being carried up on the fruit-bearing stalk and converted into the *calyptra*. In general, a single archegonium only becomes perfect and undergoes these changes, the rest being found in an abortive state. These two distinct kinds of floral organs sometimes exist in the same flower and are enclosed in the same perichæcium, when the moss is called syncæious; if, however, the antheridia occur on one part of the plant and the archegonia on another part, the moss is called monocæious; and when each kind of organ occurs on separate plants, the moss is dicecious. The importance of these differences in the mosses is apparent from the fact that some species produce in some countries only barren flowers or antheridia, and consequently can never be found there in fruit, a condition always desirable to those who collect for herbariums. It has been well ascertained that where the antheridia are wanting the archegonia never come to perfection; and there are some dicecious species of *Hypna* for instance, which are usually destitute of capsules from that cause.—Having noticed the changes which take place in the archegonia as they proceed in their development, the structure of the antheridium and its probable function should be regarded. The structure of the contents of the antheridium is indeed very curious, and was first well observed by Unger. In the *sphagnum*, at the period of inflorescence, this anther-like organ bursts at its apex, when it is found to be filled with minute bodies (*spermatozoides*, Schimpfer), consisting at first of hemispherical cellules containing each a phytozoon, as before noticed. This takes the form of a spirally coiled fibre of one turn and a half attached to one end of an opaque greenish corpuscle. When immersed in water, as on the slide of the microscope, the corpuscle and fibre exhibit a great variety of movements. The function of the phytozoon is regarded as belonging to impregnation. This having taken place, the future fruit is the next effort. The separation of the epigone into *vaginula* and *calyptra* implies generally the lengthening of the intermediate portion, which thus becomes the *seta* or footstalk of the capsule. That portion which is carried upward and is under the *calyptra* is termed the *sporangium*. At first the sporangium is no more than a mass of cellular tissue, the cells of which are homogeneous and contain green matter. When mature it is an urn-like body, with a cellular, central axis called the *columella*, containing spores. In some instances

the sporangium is indehiscent (e. g., *placum*); in other cases it opens either by 4 lateral valves (*andrea*) or by means of a lid (*operculum*). This lid is thrown off when the sporangium is mature. Between the base of the lid and the edge of the mouth of the capsule or sporangium are frequently several rows of large cells forming a sort of ring (*annulus*), which distend themselves and assist in the dispersion of the spores. The edge of the mouth of the capsule in some mosses is entire (e. g., *gymnostomum*), or it has a fringe (*peristome*) consisting of prolongations and divisions of the two inner parietal layers of the capsule. The peristome consists of one or more rows of hygrometric cellular teeth, which are 4 or some multiple of that number. Where but a single row exists, the mosses are classed as *aploperistomi*, and as *diploperistomi* where there are double rows. The teeth are long and twisted together in *barbula*, or bifurcate in *dieranum*, or assume a variety of shapes, marking the different genera. In some mosses the inner parietal layer appears as a membrane called the epiphragm or tympanum, stretched across the mouth from the walls of the sporangium to the columella. The capsule does not always rest in a perpendicular manner upon the seta, but may be inclined to one side, and bent downward or cernuous; and in some mosses one side of it is more developed than the other, producing an unsymmetrical shape. Sometimes there is a considerable thickening or swelling at its base, to which the name of *apophysis* is given. The interior of the mature capsule is filled with a profusion of dust, which however will be found to consist of round bodies, which are in fact the spores or seeds. When they have been ejected from the capsule, they are in a condition to grow. From some part of their surface a bladder-like swelling protrudes, which after a while extends itself by increase of similar ones into a confervoid thread. An entangled mass of such threads soon covers the soil, or the moist surfaces of substances on which the spores have fallen. So much do these threads resemble some of the algae, that they were mistaken for them by the earlier botanists. This confervoid vegetation continues from 10 to 20 days, when upon its surface very small buds appear. On examination these buds will be found to be composed of minute scale leaves, and thus the axis or future stem is originated at their base. In some genera the moss scarcely develops itself beyond this condition, forming its fruit in the interior of the scale-like frond. In other kinds of mosses the plants grow for a shorter or longer period of time before the inflorescence appears. These confervoid threads have been compared to the primordial leaves of the higher orders of plants; they differ however in this, that on disappearing from the surface of the soil, similar threads penetrate it, and seem to careless observers to be the roots. In many mosses such seeming roots are produced from the under side of the stem, or even from the very extremities, in the progress of its growth.

—Very little is known of the uses of the mosses. In the economy of nature they serve as precursors of the higher plants, appearing first upon sterile places, and collecting among their matted and tufted stems the dust and sand. In winter they afford secure lodging places for insects, as well as food for them in summer. Some species of *sphagnum* seem to enter largely into the formation of peat bogs, growing in stagnant pools and ditches, and attaining to great length of stems. When taken from the water and thoroughly squeezed, the *sphagna* serve an excellent purpose for the transmission of trees and large plants by packing their roots in the spongy and elastic mass. Some *hypna* retain their elasticity on being dried, and serve for stuffing pillows. The Laplanders use turfs of *polytricha* for mattresses. Little brooms are sometimes made of these mosses. In dense forests the northern side of trees is usually more thickly covered with mosses than the other sides. Some fanciful medicinal qualities are attributed to a few kinds.—The geographical distribution of the mosses is very extensive. Scarcely any part of the earth's surface is destitute of them, from the polar regions to the equator. They constitute with lichens almost the only vegetation on the coast of the Polar sea, where the soil never thaws to a depth of more than a few inches. The northern sea coast of Siberia is an immense morass whose entire surface is covered with mosses. The schistose rocks of Spitzbergen, rising above the everlasting ice, are, according to Martens, covered with these plants. They enter largely into the flora of Greenland; the loftiest Swiss Alps, and the volcanic scorias of Iceland, afford abundant species. Montagne in his *Sylloge* exhibits species from almost every portion of the globe, and the various exploring expeditions find these forms of vegetation wherever they have visited.—The earliest writer on the mosses who comprehended their structure was Micheli, who in 1729 described and depicted the most minute portions of their reproductive organs, and seems to have understood their purposes. On the other hand, Dillenius (1741), Linnæus (1753), and Adanson (1768) regarded the sporangium as analogous to the anther of the phanogamous plants. Schmiedel in 1760, and subsequently in his *Icones Plantarum et Analyses Partium* (1762-'97), described and figured the *zootheca* of the *hepaticæ*; and, struck with finding them filled with a mucilaginous fluid analogous to that which fills the pollen grains, he considered them as male organs, and gave the name of female organs to the sporangia of mosses. Hedwig (*Theoria Generationis*, 1784) and other botanists now adopted the same view, until H. Mohl in 1838 showed that the spores of the *Hepaticæ* and mosses were developed exactly like the pollen grains, and that the ideas of Linnæus and others of that school were in a measure correct. We have seen, however, that the antheridia with their enclosed phytozoa seem to be essential in the production of the sporangium and its contents, though in what way is

not precisely known. In the United States the mosses were perhaps first collected by the celebrated Dr. Muhlenberg, a minister of the German church at Lancaster, Penn. He sent many American species to Hedwig, and they were described and published in the *Species Muscorum* (Leipsic, 1801). In 1813 Muhlenberg's *Catalogus Plantarum America Septentrionalis* (Lancaster) appeared, in which he gives the names of more than 170 species. The value of this list is apparent, when it is known that his correspondence abroad was extensive and highly prized. Many of the species in Bridel's *Bryologia Unicera* (Leipsic, 1826) were from contributions of Dr. Torrey of New York, who at that time had made ample collections of cryptogamic plants; and mention is frequently made by the same author of the names of Cooley and Dewey, who likewise furnished specimens. Those of Newfoundland had been collected by De la Pylaie. A synoptical table of the ferns and mosses of the United States was published in 1828 in Silliman's "American Journal of Science and Art," vol. xv., by Dr. Lewis C. Beck. A list of the mosses of Massachusetts is appended to the 2d edition of Prof. Hitchcock's "Geological Report" of that state. The mosses of the British possessions in North America were collected by Drummond, the celebrated author of *Musci Scotici*, who accompanied Franklin in his 2d land expedition in 1825. These subsequently appeared in sets of mounted specimens published by William Wilson at Glasgow in 1828; they were choice and valuable. In the Boston "Journal of Natural History" for 1845 (vol. v.), is a paper by John L. Russell on some species noticed by him in eastern Massachusetts; and in Hovey's "Magazine of Horticulture and Botany" for 1847, vol. xiii., is a valuable list of White mountain species prepared by William Oakes, who had made that region of New England his especial study. In the catalogue of the plants of Cincinnati, Ohio, by the late Thomas G. Lea, are more than 80 species collected by him. In Agassiz's "Lake Superior, its Physical Character, Vegetation," &c. (Boston, 1850), the mosses of that region are elaborated by Lesquereux. Dr. Darlington, in the 2d edition of his *Flora Cestrica* (Philadelphia, 1853), furnishes a list of species detected within the limits of Chester co., Penn., and prepared by Thomas P. James, Esq. The *Musci Alleghanienses* were issued from Columbus, O., in 1855, in 2 4to. fascicles, consisting of 215 species and well marked varieties of mosses, and 177 species of *hepaticæ*. Fifty copies only of this superb work were printed for private distribution among the friends of the author. These specimens were collected by William S. Sullivant, Esq., and Prof. Asa Gray, in a tour along the Alleghany mountains from Maryland to Georgia in 1853. A similar work from the joint studies of Lesquereux and Sullivant, consisting of 355 mounted specimens, and entitled *Musci Boreali-Americani* (Columbus, O., 1856), full of rich and well fruited species, and thus giving a view of the muscology of

North America, furnishes the student in this department of botany ample materials for comparison. In the 2d edition of Prof. Asa Gray's "Manual of the Botany of the Northern United States" (New York, 1856) can be found good descriptions of all the species known eastward of the Mississippi river, derived from the most careful study of the ample materials at the command of these botanists. A description of the mosses and liverworts found on the United States Pacific railroad expeditions and surveys, with figures of the rarer and new species by Mr. Sullivant, can be found in the 4th volume of the executive documents (senate) of the 38d congress, 2d session (Washington, 1856). Other valuable contributions in this branch of botany from the same pen are to be seen in the "Memoirs of the American Academy of Arts and Sciences" (Boston, 1848, &c.). The species found in Wisconsin are given by I. A. Lapham, Esq., in the 5th volume of the "Transactions of the Wisconsin State Agricultural Society" (1860). Many novelties likewise have been brought to notice through the labors of C. O. Frost of Brattleborough, Vt., and by Prof. D. O. Eaton of New Haven, who have minutely examined that region. The southern species have received the attention of botanists, and approximations to tropical forms have been detected.

MOSS TROOPERS, a species of banditti or freebooters who formerly infested the borders of England and Scotland, and were so called from the character of the country, composed largely of mosses or morasses. After the union of the two crowns they gradually disappeared, and for upward of 150 years have been extinct.

MOSUL, or **MOUSSUL**, a town of Asiatic Turkey, in the province of Al Jezirah or Mesopotamia, on the right bank of the Tigris, 220 m. N. N. W. from Bagdad; pop. about 85,000, of whom 9,000 are Christians, 1,500 Jews, and the rest Arabs, Turks, and Koords. It is the capital of an eyalet of its own name. Its fortifications are in a very dilapidated condition. The streets are narrow and irregular; the houses, mostly of stone or brick, have commonly vaulted roofs surrounded by flat terraces. Coarse cottons and shawls are manufactured. Mosul was once famous for the manufacture of muslin, which is said to have derived its name from this town. In the vicinity are several hot sulphur springs which are much frequented. Mosul is chiefly interesting as being near the site of Nineveh, whose remains exist in great mounds on the opposite side of the river, excavated by Botta and Layard.

MOTAGUA, Rio. See **GUATEMALA**, vol. viii. p. 539.

MOTET (It. *mottetto*), an elaborate vocal composition, consisting of from 1 to 8 parts, and generally of a sacred character. The Latin psalms and hymns of the Roman Catholic church are frequently so called, and in general the term may be applied to any sacred vocal composition which does not come under the character of a mass or anthem.

MOTH (*phalena*, Linn.), the common name of the 3d and last section of the order *lepidoptera*, the other two having been described under **BUTTERFLY** and **HAWK MOTH**. This section includes a great number of nocturnal insects, also called night butterflies and millers, including all that cannot be arranged under the other sections, whatever be their food or the ways in which they are beneficial or injurious to man. They vary greatly in size, color, and form; while those with gilded wings are very minute, the atlas moth of China (*attacus atlas*) covers a space 9 by 5½ inches with its expanded wings, and the owl moth of Brazil (*crebus striz*) expands 11 inches. The antennæ are usually tapering, either naked or feathered, varying according to sex, and amplest in the males; the wings are bridled by bristles and hooks, the first pair covering the posterior, and more or less sloping when at rest; some females have very small wings or none at all; the hind legs have 2 pairs of spurs. The tongue in most consists of a sucking tube formed of 2 hollow threads, rolled up when not in use; in some it is very short or wanting; there are generally 2 feelers, curving upward from the lower lip. The legs in the larvæ vary from 10 to 16; some in this condition are smooth and naked, others hairy uniformly or in tufts, others warty or spiny; some enclose themselves in silken cocoons (as the silkworm), others enter the ground, or undergo their change in the interior of plants; the chrysalides are of an oval shape, without angular elevations. Most moths conceal themselves by day in cracks and dark places, under leaves, stones, &c., flying only at night and during the warm season; a few, however, as some *bombyces*, fly by day and in the brightest sunlight. Modern entomologists generally recognize 7 groups of moths, as follows: I. *Bombyces* or spinners, including Latreille's 4 sections of *hepialites*, *bombycites*, *pseudo-bombyces*, and *apocura*. This, the largest group, was so named from *bombyx*, the old name of the silkworm, and its members are generally thick-bodied, with feathered antennæ (at least in the males), very short or no feelers, with wings on the thorax, and the fore legs often hairy; the caterpillars have 16 legs, and in most cases spin cocoons in which metamorphosis takes place. After Boisduval, Dr. Harris divides this group into 9 families: 1. *Lithoriada*, so called from their caterpillars living in stony places and often feeding on the lichens growing upon rocks. Many of the species are very handsome, but are injurious from devouring grass; they are of small size, slender bodied, with long bristly antennæ, narrow fore wings, and smooth back; they often fly in the daytime; their caterpillars are sparingly clothed with hairs growing in clusters from small warts, and enclose themselves in cocoons of silk interwoven with their own hairs. The rings of the chrysalides are closely joined. The most elegant species is the *driopis*, with white body, thorax dotted with black, and wings deep yellow crossed by about 6 black-

dotted white bands, the hind wings scarlet bordered with black behind, and a spread of about $1\frac{1}{2}$ inches; it can hardly be called injurious to vegetation. 2. *Arctiada*, tiger and ermine moths, called woolly bears from the thick hairy covering of most of their caterpillars; the tongue is generally very short, and the antennæ doubly feathered on the under side, hardly visible in the females; feelers shorter and thicker than in the preceding family; wings roofed on each side, thorax thick, abdomen short and plump, generally with black spots; they fly only at night; the hairy caterpillars run very fast, and when irritated roll themselves into a ball; some, like the salt-marsh caterpillar and the yellow bear, are very injurious to vegetation; when about to change they creep into a protected place, and make a cocoon of their own hairs and a little silk; the chrysalis is smooth, with movable joints. Most of our tiger and ermine moths belong to the genus *arctia* (Schr.). The largest is the *A. virgo*, which gives out a very disagreeable odor; it expands $2\frac{1}{2}$ inches, and the wings are reddish; the larva is brown. The great American tiger moth (*A. Americana*), represented in Europe by the *A. caja*, expands $2\frac{1}{2}$ inches; the fore wings are brown marked with white, and the hind ochre yellow spotted with blue black, and with a white edge of the collar; the caterpillar is blackish brown. The yellow bear (*A. Virginica*) is very common and destructive in gardens, devouring almost all kinds of plants; the moth is called the white miller, and would be called an ermine moth in England. The salt-marsh caterpillar (*A. aceræa*) is a great pest to the salt hay crop; it appears toward the end of June, attaining the full size during August, then measuring nearly 2 inches in length. The Isabella tiger moth (*A. Isabella*) is remarkable for the stiffness and evenness of its hairy covering, black toward the head and tail and tan-red between, with black body and head; the moth is tawny yellow with black dots, and the antennæ are not feathered. Some arctians devour the leaves of trees, the most familiar and destructive of which are the fall web worms (*A. textor*), whose large webs so often disfigure our fruit and ornamental trees toward the end of summer; the brood make a web in common, sometimes extending over entire branches, and feed in company under its protection, devouring the upper and pulpy portion of the leaves; when full grown they are a little more than an inch long, and are thinly clothed with hairs; the general color is greenish yellow dotted with black, the head and feet black; the moths are white, with tawny yellow fore thighs and blackish feet; the wings expand about $1\frac{1}{2}$ inches. For full descriptions of these and other arctians, see Dr. Harris's work on the "Insects Injurious to Vegetation." 3. *Liparidæ*, so called from the thickness of the body of the females, which are sometimes destitute of wings, while the slender males have broad wings; the antennæ are bowed and doubly feathered below; the feelers are very hairy, as are the fore legs; the males some-

times fly by day. The caterpillars are in most half naked, the thin hairs growing chiefly on the sides; they are called tussocks in England, and have sometimes proved so destructive there that prayers were offered in the churches to stay their ravages; they are far less common and injurious in this country, where they are called vaporers moths; they belong to the genus *orgyia*, among others. 4. *Lasiocampadæ*, with very thick woolly bodies, without the usual bristles or hooks to the wings, with the front edge of the hind wings turned up; the larvæ are generally not warty, and are sparingly clothed with short soft hairs, mostly on the sides; both sexes are winged, and fly only at night. Here belong the tent or lackey caterpillars so common in neglected orchards; the eggs are placed as little cylinders around the ends of branches, and the larvæ when hatched make a tent like a spider's web between the forks of the branches of apple and cherry trees; they make this in common, and remain under it except when eating; they spin from the mouth a silken thread which serves to conduct them to the tent in their search for food, and their pathways become in time well carpeted and secure from this cause. They are called lackeys in England, and *litrées* in France, from their parti-colored livery of white, black, and yellow. The American tent caterpillar or lackey (*clisiocampa Americana*) is so abundant and so well known as one of the worst enemies in the orchard, as to receive in many districts the name of "the caterpillar." The lappet moths are so called from the hairs which grow from fleshy or warty appendages that hang like legs from the sides of every ring; the American lappet moth is the *gastropacha Americana*, described in Dr. Harris's work above cited. The Chinese silkworm (*bombyx mori*), which belongs here, will be noticed under SILKWORM. The processionary moth (*B. processionæ*) is remarkable for the singular manner in which the caterpillars march, alluded to under CATERPILLAR. 5. *Saturniadæ*, containing some of the largest and handsomest moths, with thick woolly bodies, widely feathered antennæ, and wings without bristles or hooks, and generally with a conspicuous spot in the middle of each; they fly during twilight. The most beautiful of all is the luna moth (*attacus luna*), with long-tailed wings of light green expanding $4\frac{1}{2}$ to $5\frac{1}{2}$ inches, each having a transparent spot encircled with white, red, yellow, and black; the larva is bluish green, from 2 to 3 inches long, and when at rest nearly as thick as the thumb; it is found on walnut and hickory trees, and spins a strong cocoon within a cavity formed by the drawing together of a few leaves. The polyphemus moth is larger, expanding to 6 inches, of a dull ochre yellow color, without tails to the wings. The *A. Cecropia* expands to $6\frac{1}{2}$ inches, with rounded untailed wings of a grizzled dusky brown, with a red eye spot with white centre and black edge. The *A. Promethea* expands to about 4 inches. All these moths make very large cocoons entirely of silk, far

surpassing in strength those of the silkworm, and capable of being manufactured into very durable fabrics; the first two are well worthy the serious attention of persons interested in silk culture. Two other moths of this family, whose processionary larvæ are furnished with severely stinging prickles, are the *Saturnia Io*, expanding from 2½ to 3½ inches, and the *S. Maia*, resting like the former with the wings closed, expanding to about 8 inches. 6. *Ceratocampa*, or horned caterpillars, being armed with thorny points, some of the anterior long and curved like horns; in the moths the short antennæ are feathered at the basal half and thence naked to the tip; the wings, closed when at rest, have no hooks nor bristles; this family, according to Harris, is exclusively American. One of the largest, rarest, and most magnificent, is the royal walnut moth (*ceratocampa regalis*), expanding 5 or 6 inches, the fore wings olive-colored with yellow spots and red lines, the hind wings orange red with yellow patches and olive spots; the horns of this formidable-looking larva are unable to wound. Other horned larvæ belong to the genus *dryocampa*, as the imperial moth (*D. imperialis*), with yellow wings sprinkled and spotted with purple brown, expanding to about 5 inches. 7. *Zeuserada* or *hepialida*, whose larvæ are concealed in the wood and pith of plants like the borers of the hawk moths; these larvæ are whitish, soft, nearly naked, with horny heads, and 16 legs; they make imperfect cocoons. Here belong the ghost moth of Europe (*hepialus humuli*), very injurious to the hop vine; the famous *cossus ligniperda*, so destructive to the elm and willow, minutely described by Lyonnet, and hence called by an enthusiastic Frenchman "the immortal worm;" and various borers of the locust tree in this country, the carpenter moths of the genus *xyleutes* (Newman), which includes the *C. ligniperda*; the last are sometimes called goat moths from the strong odor which they emit. 8. *Psychada*, or sack-bearers, from the larvæ bearing about with them cases in which they live, made of bits of straw, leaves, and sticks, and lined with silk; they undergo their change within these; here belong the genera *psycha*, *acetius* (drop or basket worms), and *perophora*. 9. *Notodontada*, so called from the hunched or toothed back of the larvæ; some are naked, others slightly hairy, with 16 legs, of which the last pair are sometimes modified into a forked caudal appendage; some seem to be without legs, showing only the soles of the feet. Here belong the odd-shaped *limacodes* or slug caterpillars, found on forest and orchard trees; the *dioranura* or fork tails, the last pair of legs being held upward; and the various species of the old genus *notodonta*, as the *N. unicornis* and *concinna*. II. *Noctua* or owl moths, equivalent to the *noctualites* of Latreille, so called from their flying chiefly at night like owls. This tribe contains many thick-bodied and swift-flying moths, which generally have long and tapering antennæ, long tongue, distinct

feelers, wings fastened by bristles and hooks and roofed when at rest; the colors are usually dull, and shades of gray or brown; the larvæ are for the most part naked, slow-moving, usually with 16 legs, and nearly cylindrical; some make cocoons, while others go into the ground to transform. Their injury to vegetation is considerable. Among them are the maple moths (*apatela*) of America and Europe; the nonagrians, like the spindle worms; the agrotidians or rustic and dart moths and cut worms; and the mamestrians, like the zebra, painted, and wheat caterpillars, and cotton worms. III. *Geometra* or *phalanites* of Latreille, including the geometers, span worms, and loopers, so called from their manner of moving. The characters of this tribe are sufficiently given under CANKER WORM; they arch their backs when creeping, and when in repose fix themselves by their hind feet and extend the body immovable like a twig or branch. It contains the genus *phalana*, which has been divided into many sub-genera. IV. *Pyrallides* or delta moths (included in the *deltoides* and *tineites* of Latreille), nearly allied to the geometers, and so called from the triangular Δ form of the closed wings; the body is long and slender, the fore wings rather narrow and elongated, antennæ long and generally simple, and the legs slender; most of them fly by night, preferring moist localities. Here belong the meal moth (*pyralis farinalis*), the grease or tabby moth, the day-flying *simaethis* (remarkable for their gyrations after alighting), the aquatic *Hydracampa*, &c. (living in cylindrical leafy cases in the larva state), and the hop vine *Hypera*. V. *Tortrices* or leaf-rollers, so named from the habit of most of their larvæ of making rolls of leaves fastened by silk, serving both for habitations and food; they have 16 legs, and are mostly naked. The moths rarely expand more than an inch, and carry their wings when at rest like a steep roof; the fore wings are very broad at the shoulders, and are generally prettily banded and spotted; the hind wings are plain; the antennæ thread-like, the tongue short, the body thick, and the legs short; they fly only at night, and are most abundant in midsummer. The bud caterpillars are frequently very injurious in orchards and flower gardens, fastening the tender leaves together and eating the substance of the bud, and some go into and destroy young fruits; apricots, peaches, and plums often suffer much in this way. The turpentine moths pierce the tender shoots and terminal buds of the fir and pine trees, the extent of their depredations being indicated by the oozing of the resin. The apple worm, the larva of the *carpocapsa pomonella* (the codling or apple moth) is unfortunately too well known to fruit growers; the moth, which expands 1½ to 2 inches, may be known by a large oval brown spot, edged with copper, on the hinder margin of the fore wings; they lay their eggs on the young summer apples in July evenings, depositing them one by one in the hollow at the base

som end of the fruit; the larvæ are hatched in a few days, and at once burrow toward the centre, only one being commonly found in each fruit; it reaches the full size in about 8 weeks, by which time it has burrowed in various directions, getting rid of the refuse fragments by a hole which it gnaws in the side, through which it also escapes after the premature fall of the fruit; they make silken cocoons, and are not generally changed to moths till the following summer, though in some cases the earlier worms may become moths the same year and lay eggs of a second generation. Pears and cranberries are affected by a worm apparently the same as that of the apple. VI. *Tineæ* (*tineites*, Latr.), the moths *par excellence* of the household, the destroyers of clothing, furs, &c., and those referred to in the Scriptures and the old writers. The larvæ are smooth, with 16 feet, living usually in cases made from the fragments of the substances which they devour fastened together with silk, in which they move freely and unseen. Though the smallest of the *lepidoptera*, they are among the most beautiful and the most destructive. Here belong, among the *crambidae*, the bee or wax moth (*galleria cereana*), whose depredations in hives have been noticed under BEE; among the *tineada*, the clothes moth (*tinea vestianella*), carpet moth (*T. tapetella*), fur moth (*T. pellionella*), hair moth (*T. erinella*), and grain moth (*T. granella*); and among the *yponomentada*, the pack moth (*anacampsis sarcitella*), destructive to wool and its fabrics, and the Angoumois grain moth (*butalis cereatella*). Objects of natural history, articles of food, and even books have their destroyers in the shape of the larvæ of these minute moths. The best preventives against moths in household articles are to put them away before May or June where the moths cannot reach them when about to lay their eggs; to expose them to the air and sun for hours, after a good beating to dislodge any insects or eggs; to brush over their retreats with turpentine; to strew camphor, black pepper, tobacco, or shavings of Russia leather under or among carpets, woollens, furs, or feathers, when they are put away for the summer; the use of camphor wood or cedar trunks; corrosive sublimate washings, tobacco and sulphur fumigations, and the action of heat and steam. For an account of the American and European grain moths, see WHEAT MOTH. VII. *Alucita* or feather-winged moths, equivalent to the *pterophorites* of Latreille. These may be known by the longitudinal division of their wings into narrow fringed branches like feathers; the antennæ are slender and tapering, the tongue long, the body and legs long and slender, the wings at rest not covering the body, but standing out like a folded fan; the flight is slow and feeble, sometimes diurnal, sometimes nocturnal; the larvæ are short and thick, slightly hairy, with 16 legs, living on leaves and flowers, and constructing no cases. There are few species, and they are rarely injurious to man.

MOTHER CAREY'S CHICKEN. See PEARL-TREE.

MOTHER OF PEARL. See PEARL.

MOTHERWELL, WILLIAM, a Scottish poet and journalist, born in Glasgow, Oct. 18, 1797, died in that city, Nov. 1, 1835. He was educated chiefly at the grammar school in Paisley, and at the age of 15 was placed in the office of the sheriff clerk of that place. In 1819 he was appointed sheriff clerk depute of the county of Renfrew, and held that situation until 1829. He early developed a taste for the antique, suggested perhaps by his frequent researches among old manuscripts in the sheriff's office, and which impregnated most of his poetry. He possessed also a remarkable talent for drawing figures of men in armor and similar designs, which even in his school days attracted the attention of his teachers. As early as his 14th year he is said to have sketched the outline of his well known poem, "Jeannie Morrison," the heroine of which was a school companion of his childhood; but he does not appear to have occupied himself seriously with poetical composition previous to 1818-'19. In the latter year he edited the "Harp of Renfrewshire," a collection of songs and poems by Renfrewshire poets, with an introductory criticism; and he subsequently contributed articles in prose and verse to the "Paisley Advertiser." In 1827 appeared his "Minstrelsy, Ancient and Modern," with an elaborate historical introduction and notes, a work containing several original poems in antique guise, and which brought him into direct communication with several distinguished literary men. Subsequently he edited for a year the "Paisley Magazine," and printed in it some of his best poems, and between 1828 and 1830 conducted the "Paisley Advertiser." In the latter year he took charge of the "Glasgow Courier," a journal of very decided tory principles, with which he remained connected until his death. In 1832 he published a collection of his poems, most of which, in consequence of his absorbing duties as a political journalist, were fugitive, and soon after commenced in conjunction with James Hogg an annotated edition of Burns's works, which he did not live to complete. In 1849 a greatly enlarged edition of his poetical remains, accompanied by a memoir, was published in London.

MOTHERWORT (*leonurus cardiaca*, Linn.), the name of a homely plant introduced from Europe, belonging to the mint family or natural order of *labiata*. It is frequently met with around walls, fences, and neglected spots near farms and gardens. The root of the motherwort is perennial, stem 2 to 5 feet high, branching near the base, large and downy; leaves 2 to 4 inches long, lobed and broad, growing narrower toward the top of the stem, the uppermost entire, all bending downward, and downy underneath. The flowers, which will be found to be very pretty if carefully examined, are borne in many whorls; the calyx has rigid and prickly teeth; the corolla, hairy without, is variegated

with white and red; the seeds are triquetrous, truncate at summit, hirsute, and numerous, and freely vegetate, helping to render the species, as Dr. Darlington ("Useful Plants and Weeds") observes, an unsightly and disagreeable weed. Another species (*L. marrubiastrum*, Linn.), he adds, has become partially naturalized in some districts of Pennsylvania, but does not threaten to become so prevalent and troublesome. The common motherwort has a strong, pungent odor, and, as its name indicates, is principally used as a medical remedy in diseases of females; in hysteria, nervous complaints, morbid nervous excitability, in many chronic diseases when attended with restlessness, wakefulness, spinal irritation, neuralgic pains in the head, stomach, and liver. The infusion of the root is diuretic; the seeds have been given in bilious colic; a decoction of the plant is frequently used in menstrual colic, suppression of the menses, and lochia.

MOTLEY, JOHN LOTHEROP, an American historian, born in Dorchester, Mass., April 15, 1814. He was graduated at Harvard college in 1831, and thence proceeded to the university of Göttingen, where he continued about one year, and another year at the university of Berlin, after which he travelled for some time in the south of Europe, chiefly in Italy. On his return to America he studied law, and was admitted to the bar in 1836-'7. He displayed little liking for the drudgery of the law, and scarcely practised his profession. In 1839 he published a novel entitled "Morton's Hope, or the Memoirs of a Young Provincial." In 1840 he received the appointment of secretary of legation to the American embassy to Russia. He held the post about 8 months, when he resigned and returned to the United States. In 1849 he produced a second historical fiction, entitled "Merry Mount, a Romance of the Massachusetts Colony." This work, like the preceding, although well written, and giving abundant evidence of talent, attracted little attention. Meanwhile he had contributed various articles to some of the leading reviews. Among these papers, one on De Tocqueville's "Democracy in America," and another on Goethe and his writings, appeared in the "New York Review." Still another of very striking character, on Peter the Great, was published in the "North American Review" for Oct. 1845. Soon afterward he became interested in the history of Holland, and began to collect authorities for a work on that subject, writing enough to form two volumes; but, unable to gather such material at home as he deemed necessary for the thorough prosecution of the subject, he embarked for Europe with his family in 1851. On examination he became dissatisfied with his labors, threw aside all that he had written, and began his entire task anew. In Berlin, Dresden, and the Hague, he passed the principal portion of his time during the next 5 years, engaged upon the composition of his history, entitled "The Rise of the Dutch Republic." It was published in London in 1856

(3 vols. 8vo.), and was at once reproduced in New York. It was also reprinted in English at Amsterdam, beside being translated into Dutch under the supervision of the historian M. Bakhuizen van den Brink, who prefixed an introductory chapter. A German translation was published at Leipsic and Dresden; and the 1st volume of a French translation, with an introduction by Guizot, was published in 1859. The sale of the work in England, to Nov. 1857, had reached 15,000 copies; and in America, up to June, 1860, 7,590 copies had been printed. Mr. Motley visited the United States for a short time in 1858. He is now in Europe pursuing his researches regarding the history of Holland. A new work entitled "The United Netherlands" (3 vols. 8vo.) is announced (Oct. 1860) for publication in London. Since the publication of his "Dutch Republic" he has been elected a member of various learned societies in Europe and America, among them of the institute of France in place of Mr. Prescott, deceased. In 1860 he received the degree of D.C.L. from the university of Oxford, and that of LL.D. from Harvard college.

MOTION. See MECHANICS.

MOTMOT (*momotus*, Briss.), a genus of American fissirostral birds of the family of rollers and sub-family *momotinae*. The single genus is characterized by a bill rather long, slightly curved, with compressed sides, hooked and obtuse tip, and lateral margins serrated; wings moderate and rounded, with 4th to 6th quills nearly equal and longest; tail lengthened and graduated, with the 2 middle feathers usually longer than the others; tarsi as long as the middle toe, covered in front with narrow transverse scales; toes unequal, the outer nearly as long as the middle and united at the base as far as the 2d joint, the inner short and slightly united, the hind short and weak, and the claws compressed and curved; the tongue is long and barbed as in the toucans. The name is derived from the peculiar notes. There are about a dozen species, bold and wild, inhabitants of tropical America and the West Indies, especially in the deep shades of the forests or gloomy recesses of old buildings; they are usually solitary in the daytime, perching with the head drawn between the shoulders, solemn and still except for an occasional melancholy croak; they are most lively at early morning and in the dusk of evening, pursuing insects in short flights; they also eat fruits, lizards, and snakes, which are tossed into the air from the point of the bill and swallowed; they sometimes devour the eggs of other birds. The nest is made in holes of trees or banks of earth. They are said to peck off the barbs from a portion of the stem of the central tail feathers, leaving a rounded feathered surface at the tip. The best known species is the Brazilian motmot (*M. Brasiliensis*, Lath.), about the size of a blackbird, of a deep rich green color, with bluish forehead, violet back of head, and black crown. The movements are awkward on the ground.

MOTT, LUCRETIA, an American minister of the society of Friends, born in Nantucket, Jan. 8, 1793. Her parents, Thomas and Anna Coffin, were natives of that island, and removed thence to Boston in 1804. After attending school in that city for 2 years, she spent 8 years at a Quaker boarding school in the state of New York, the latter part of the time as assistant teacher. There her attention was first called to the duty of abstaining from the use of slave produce, and succeeding years deepened her convictions. In 1809 she went to Philadelphia, to which city her parents had removed, and in 1811 she married James Mott, who entered into partnership with her father. The depression in business consequent upon the war of 1812, and the death of Mrs. Mott's father, soon after made it necessary for her to engage in business with her husband. In 1817 she took charge of a large day school in Philadelphia, until compelled by other duties to relinquish it. Soon after this, in her 26th year, her labors as a preacher began. After an interval of several years devoted to the care of a family of 6 children, she travelled through New England, Pennsylvania, Maryland, and a part of Virginia, preaching against slavery, and advocating the peculiar tenets of the society of Friends, obedience to the inward light, and a steadfast adherence to peace principles. At the time of the division in that society in 1827, Mrs. Mott adhered to the Hicksite party, opposing any approximation to a more orthodox faith, and earnestly urging the duty of negro emancipation, and of abstaining from the use of goods obtained by slave labor. She took an active part in the organization of the American anti-slavery society in Philadelphia in 1838, and with other abolitionists was subjected to the mob violence which resulted in the burning of Pennsylvania hall, a new building opened for anti-slavery meetings. Notwithstanding the odium attaching to the name of abolitionist at that time, she continued to preach against slavery, advocating the interests of the negro race, speaking occasionally in their churches, and aiding in their charitable associations. She was a delegate to the world's anti-slavery convention held in London in 1840, but was excluded from a seat as delegate, the right of women to take part in public assemblies being denied by a majority of the members. At the same time, she with the other delegates received every courtesy and attention; and as strangers and abolitionists, they were welcomed to the convention. In 1848 the first woman's rights convention was held at Seneca Falls, N. Y.; and Mrs. Mott took an active part in that and subsequent conventions, which have been held annually, for advocating the equal rights of women. After the passage of the fugitive slave bill, Mrs. Mott attended all trials of fugitive slaves in Philadelphia, encouraging them by her presence and words of sympathy, and endeavoring to evoke a public sentiment in opposition to their surrender to their masters.

MOTT, VALENTINE, M.D., LL.D., an American surgeon, born at Glen Cove, Long island, Aug. 20, 1785. His father, Dr. Henry Mott, practised medicine for many years in the city of New York. The son was graduated as M.D. at Columbia college in 1806, and proceeded to London, where, as well as in Edinburgh, he studied clinical surgery and medicine under the most eminent professors. On his return in 1809 he was called to fill the chair of surgery in Columbia college, a position which he held till the medical department of that institution was merged in the college of physicians and surgeons in 1818. Difficulties arising with the trustees and professors on principles of collegiate government, he withdrew from that school in 1826, and with Dr. Hosack, Dr. Francis, Dr. Mitchill, and others, founded the Rutgers medical college, which, owing to a question about its charter, existed but 4 years. Since 1830 Dr. Mott has lectured in New York in the college of physicians and surgeons, and in the university medical college, as professor of surgery and relative anatomy, of which latter branch of science he is the founder. His professional reputation, however, is mainly due to his original operations as a surgeon. As early as 1818 Dr. Mott placed a ligature around the brachio-cephalic trunk, or arteria innominata, only two inches from the heart, for aneurism of the right subclavian artery, for the first time in the history of surgery. The patient survived the operation 26 days, indicating the feasibility of so dangerous an undertaking; and what is most remarkable to the practitioner, Dr. Mott states that, though all apparent supply of blood vessels was cut off from the right arm, pulsation could be distinctly felt in the radial artery, and the limb presented no evidences of sphacelation. On the 26th day, however, secondary hæmorrhage having set in, the life of the patient was speedily terminated. He excised the entire right clavicle for malignant disease of that bone, where it was necessary to apply 40 ligatures; an operation which Dr. Mott himself asserts to be the most dangerous and difficult that can be performed upon the human body. Though many have tried to rob him of the originality of this operation, a priority of 80 years sufficiently establishes it as his. The patient is still living and enjoys perfect health. Dr. Mott was the first to tie the primitive iliac artery for aneurism. He has tied the common carotid 46 times, cut for stone 165 times, and amputated nearly 1,000 limbs. He early introduced his original operation for immobility of the lower jaw, and succeeded after many eminent surgeons had failed. In 1821 he performed the first operation for osteo-sarcoma of the lower jaw. He is the first surgeon who removed the lower jaw for necrosis. Notwithstanding his advanced age, he continues to fulfil the duties of a lecturer and practitioner with vigor and clearness. Sir Astley Cooper said in regard to Dr. Mott: "He has performed more of the great operations than any man living, or that ever did

live." In 1835 Dr. Mott visited Europe for his health, and travelled extensively through England, the continent, and the East. His principal works are as follows: "Travels in Europe and the East" (8vo., New York, 1842); translation of Velpeau's "Operative Surgery" (4 vols. 8vo., New York); "Anniversary Discourse before the Graduates of the University of New York" (1860); "Mott's Cliniques," reported by Samuel W. Francis (12mo., 1860); and several separate papers concerning special operations and cases, published in medical periodicals and in the "Transactions" of the New York academy of medicine. He has received many honors from learned American and European associations.

MOTTE, COUNTESS DE LA. See LAMOTTE.

MOTTE CADILLAC, ANTOINE DE LA, the founder of Detroit, born in Gascony about 1660, died subsequent to 1717. He was of noble birth, came while still young to New France, was a captain in the army in service in Acadia, and in 1689 was ordered to Versailles by Louis XIV. to furnish information in relation both to New France and the English colonies, and especially to the condition of the harbors and defences on the coast. He was ennobled by the title of *Sieur Bonagrat* and *Mount Desert*; and *Mount Desert* island and a large tract of land on *Frenchman's bay*, *Maine*, were granted to him. In 1694 he was appointed by the governor-general *Frontenac* to the command of *Michilimackinac*, then the most important post in the Indian territory, and, next to *Montreal* and *Quebec*, the largest place in Canada. He remained here until 1697, and in 1699 visited Versailles, laid before the king his project of establishing a permanent post and settlement at *Detroit*, that should become the great centre of commerce and civilization in the north-west, and obtained the royal consent with a promise that he should be furnished with 200 settlers and 6 companies of soldiers. He returned to Canada, but the governor-general did not favor the project; and after unexpected delays and difficulties, on July 24, 1701, he landed at *Detroit* with 50 artisans and settlers and 50 soldiers, and laid the foundations of the present city, which he named *Fort Pontchartrain* in honor of the French colonial minister. He was *commandant*, and also stood in the relation of feudal lord to the inhabitants. But from the very first the little settlement had many foes, among whom were the *Iroquois*, the *Jesuits*, the governor-general, and all the Canadian officials. Unlike other posts, *Detroit* was established by the direct command of the king, *De la Motte* receiving his commission directly from Versailles; and this excited jealousy and dislike. The post itself, too, threatened to divert profitable Indian trade from *Montreal* and *Quebec*. In 1704 *De la Motte* was arrested at *Quebec* upon charges of official misconduct, but, after vexatious delays, was triumphantly acquitted. Subsequently he vindicated his conduct at the court of Versailles against similar charges instigated by his enemies. In 1711 he was ap-

pointed governor of Louisiana, then almost an unknown wilderness. Those exaggerated ideas of the boundless wealth of the valley of the Mississippi, which afterward culminated in the famous "Mississippi scheme" of John Law, were already prevailing. *De la Motte* on this new field manifested the same qualities that had ever distinguished him, but it was not within the power of man to meet the extravagant expectations that were indulged by monarch and people; and in 1717 the John Law scheme was perfected, and the government and trade of Louisiana passed into the hands of his new "Western Company." *De la Motte* returned to France. His career after this and the time and place of his death are enveloped in obscurity. He probably died soon after, or his restless activity and high ambition would have brought him into notice. His voluminous correspondence shows him the master of a clear, vigorous style, and a persuasive eloquence. He left an only daughter; and the commonwealth of Massachusetts in 1787 confirmed to his granddaughter, *Mme. Grégoire*, so much of *Mount Desert* island as was not already granted to others.

MOTTEUX, PIERRE ANTOINE, an English author, born at Rouen, in Normandy, in 1670, died in London, Feb. 19, 1718. On the revocation of the edict of Nantes he settled in London and established a large Indian warehouse in *Leadenhall street*; but, being a good linguist, he ultimately obtained a situation in the foreign letter department of the post office. His death was sudden, and attended with suspicious circumstances. Motteux acquired a complete mastery of the English language, and wrote several works in it. The principal of these are dramatic: "The Loves of Mars and Venus" (London, 1697); "Beauty in Distress" (1698); and "The Amorous Miser" (1705). He also published a poem "On Tea" in 1722, and translated "Don Quixote" (4to., London, 1701), and "Rabelais" (4to., 1708) into English.

MOULINS, or MOULINS-SUR-ALLIER, a town of France, capital of the department of Allier, on the right bank of the Allier, 213 m. by railway S. S. E. from Paris; pop. in 1856, 16,391. Cutlery, hardware, silk, and cotton hosiery are manufactured. There are 10 fairs yearly. Fitz-James, duke of Berwick, natural son of James II. by Arabella Churchill, and Marshal Villars, the antagonist of Marlborough at *Malplaquet*, were born in this town.

MOULTON, JOSEPH WHITE, an American historian, born in Stratford, Conn., in June, 1789, has resided in New York city from his childhood, where for many years he practiced the profession of the law. His curious and laborious antiquarian researches into the Dutch records and old Dutch patents of that city, and the 80 volumes of Dutch documents in the state office at Albany, brought to light the administration of Peter Minuit, the first governor or director-general for 9 years prior to that of Wouter Van Twiller. He has published a history of early New York (part I., 1894; part II.,

1826), "New York 170 Years Ago" (1849), and several works on legal subjects.

MOULTRIE, a central co. of Ill., drained by the Kaskaskia river and its branches; area, 320 sq. m.; pop. in 1855, 4,435. It has a level or undulating surface and a fertile soil. The productions in 1850 were 873,630 bushels of Indian corn, 60,040 of oats, 6,148 of wheat, and 15,368 lbs. of wool. There were 5 saw mills, 7 churches, and 880 pupils attending public schools. The Terre Haute and Alton railroad crosses the southern portion. Capital, Sullivan.

MOULTRIE, **FORT**, a fortress on Sullivan's island at the mouth of Charleston harbor, where a memorable victory was gained by the troops of South Carolina under Col. Moultrie over a British squadron commanded by Sir Peter Parker, June 28, 1776. Early in that month a fleet of 40 or 50 sail, comprising ships of war and transports conveying troops, arrived off Charleston with a view of investing the place, which was then occupied by the Americans. Hasty preparations for defence were made in the city and its suburbs, and a fort on Sullivan's island destined to command the entrance to the harbor, and which was then building under the direction of Col. Moultrie, was ordered by John Rutledge, the president of South Carolina, to be finished without delay. On the 9th Gen. Charles Lee, who held the chief command in Charleston, made a tour of inspection to Sullivan's island, and expressed much dissatisfaction with the character and position of the work, declaring that it was no better than a "slaughter pen." He subsequently advised Rutledge to abandon the post; and failing to convince him of the impossibility of holding it half an hour against the fire of the British fleet, he directed Moultrie to construct bridges for his retreat to Haddrell's point on the main land. A few days after he detached 600 men from the garrison, and took away also a large portion of the ammunition. In spite of these discouragements, Moultrie pushed forward the work with vigor. To render victory easy and certain, the British commanders had organized an attack on the fort by the fleet and another by a land force in the rear; and with this view Sir Henry Clinton had occupied with 3,000 men a low sandy island called Long island, opposite the east end of Sullivan's island, with which it was supposed to communicate by a ford at low water. The ford proved impracticable, and the further deliberations which this fact provoked, together with the prevalence of storms, preventing the fleet from coming into action, gave Moultrie many precious hours for labor. Notwithstanding these advantages, the morning of the 28th found the fort only partially completed. In its general plan it presented a "square with a bastion at each angle, built of palmetto logs, dovetailed and bolted together, and laid in parallel rows 16 feet asunder; between these rows the space was filled with sand. On the eastern and northern sides the palmetto wall was only 7 feet high, but it was surmounted by

thick plank so as to be tenable against a scaling party; a traverse of sand extended from east to west. The southern and western curtains were finished, with their platforms, on which cannon were mounted." In the rear of the fort and opposite Long island, Col. Thompson, with 800 men and 2 cannon, was posted behind a series of breastworks to resist the landing of Clinton. The fort mounted 31 guns, and the garrison consisted of 435 men, rank and file. To the last Lee counselled the abandonment of the work, telling Moultrie that the British fleet would knock it to pieces in half an hour; to which the latter replied: "We shall then fight them behind the ruins. I am not at all uneasy," he added, "we shall beat them off." At 10½ A. M. the British fleet got under weigh, and soon after the Active of 28 guns, the Bristol of 50 guns, in which was Sir Peter Parker, the Experiment, also of 50 guns, and the Solebay of 28, anchored with springs on their cables about 350 yards from the fort, against which they commenced a furious cannonade. The Thunderbomb covered by the Friendship also threw a number of shells against it. To the surprise of all on board the fleet, the repeated broadsides from the heavy frigates seemed to produce little or no effect upon the fort, in the soft, spongy wood of which the balls were harmlessly buried. Far otherwise, however, was the result of the fire upon the ships. Moultrie, having a limited supply of ammunition, discharged his guns with such deliberation that every shot told upon the hulls or rigging of the enemy. The admiral's ship in particular became the target at which the garrison aimed, and so great was the slaughter on board that at one time only Sir Peter Parker remained on the quarter deck. The other ships suffered proportionally. Meanwhile Sir Henry Clinton attempted to cross over to Sullivan's island and coöperate with the fleet; but his detachment had hardly embarked in boats for that purpose when it was recalled, it being very evident that "the landing was impracticable, and would have been the destruction of many brave men without the least probability of success." A more formidable movement of a portion of the British fleet, consisting of the Actæon, the Sphinx, and the Siren, each of 28 guns, toward Haddrell's point, whence they could have enfiladed the fort so as to render it untenable, was rendered abortive by their running aground on a bank of sand known as the lower middle ground, where they remained inactive during the remainder of the engagement. The fire between the main fleet and the fort, however, continued without cessation, the result of the conflict being watched by thousands from the wharfs and roofs of Charleston in anxious suspense. At one period the American flag, a white crescent on a blue ground, disappeared suddenly from view, and the inhabitants, supposing the fort had surrendered, prepared to defend themselves. It had however been cut down by a ball from the enemy, and was recovered by William Jasper, a sergeant, who leaped through an embrasure to

the ground amid a heavy fire, and returned in safety with the color, which he fixed on the summit of the bastion nearest to the enemy. Moultrie and his officers presented an example of equal coolness to their men, and smoked their pipes with composure during the hottest fire of the enemy. Between 1 and 2 o'clock P.M. Moultrie sent to Lee for more powder, his ammunition being nearly expended, and was advised in reply to spike his guns and retreat. Rutledge, however, sent him 700 pounds, with which he was enabled to continue his defence to such purpose that at sunset every gun on the fort but one was still in position. At that hour the enemy's fire began to slacken; the Bristol and Experiment were so riddled as to have almost become wrecks; all hope of coöperation from Clinton was abandoned, and at 9½ P. M. the ships slipped their cables and dropped down with the ebb tide to their previous moorings. Of the 3 ships which grounded, the Siren and Sphinx escaped, but the Actæon was set on fire by her crew and abandoned. At the expiration of several weeks the discomfited squadron returned to the north. The British loss in this engagement was 225 killed and wounded. The Americans lost 11 killed and 26 wounded, and the fort remained comparatively uninjured.

MOULTRIE, WILLIAM, an American revolutionary general and statesman, born in South Carolina in 1731, died in the same state, Sept. 27, 1805. He was of Scottish descent, his parents having emigrated to South Carolina at the beginning of the 18th century. At an early age he appears to have won the confidence of his fellow citizens by his cool and steady character, and in 1761 he was appointed a captain of foot in a militia regiment raised to defend the frontier against the incursions of the Cherokees. He rendered important services in this capacity, and acquired a knowledge of military affairs which proved of great advantage to him in the subsequent war of independence. He took part in the domestic agitations which prepared the popular mind for this latter event, and from the outset proved himself a firm friend of the colonies, notwithstanding some of his near relations arrayed themselves on the side of the crown. When South Carolina, following the example of the sister colonies, raised troops to resist the aggressions of the mother country, Moultrie was appointed to the command of the 2d colonial regiment, and he also represented the parish of St. Helena in the provincial congress of 1775. He was one of those who led in the seizure of the public arsenals, arms, and forts; but the approach of a British land force and fleet under Sir Henry Clinton and Admiral Sir Peter Parker, to invest Charleston, first brought his regiment into active service. In March, 1776, he was designated to construct a fortress on Sullivan's island at the mouth of Charleston harbor, and was still busy at the work when the enemy made his appearance. (See **MOULTRIE, FORT.**) In commemoration of Moultrie's bravery in defending the fort, it was subse-

quently called after his name; and he even rose in the estimation of Gen. Lee, who had strongly opposed the holding of the fort, and had desired to deprive Moultrie of his command, but who now proposed to him to lead an expedition against St. Augustine, Florida, then commanded by a brother of Moultrie, who was a royalist. Moultrie readily accepted the command, but the limited resources of the state rendered its execution impossible. He was soon after put upon the continental establishment, was made a brigadier, and had in charge the military interests of Georgia as well as South Carolina. For nearly 3 years South Carolina enjoyed an exemption from foreign attacks, her troubles being wholly internal; but in the spring of 1779 the British, who occupied Savannah in force, took advantage of the absence of Gen. Lincoln with most of the continental troops in Georgia, to make a demonstration against Charleston. In the latter part of April Gen. Prevost advanced upon the town with a large force of regular troops and Tories. Moultrie, who was stationed on the N. side of the Savannah river, with 1,000 or 1,200 militiamen drawn from the neighboring country, hastened to throw himself in his path, and, by retarding the progress of the enemy, enabled the people of Charleston to place themselves in a condition of defence. The return of Lincoln from Georgia subsequently compelled Prevost to retire to Savannah. After a brief season of repose, Charleston was in the spring of 1780 attacked for the third time by a strong land and sea force, and Moultrie, who was second in command in the town, shared in the capitulation of the American troops. While a prisoner he was approached by the British officers with offers of pecuniary compensation and the command of a British regiment stationed in Jamaica if he would leave the American service. He replied: "Not the fee simple of all Jamaica should induce me to part with my integrity." After remaining nearly two years a prisoner, he was permitted to go to Philadelphia, where in 1782 he was exchanged and released. Congress soon after made him a major-general, but too late to enable him to render any active military service to his country. In 1785 he was elected governor of South Carolina, and again in 1794. Soon afterward he retired into private life, and devoted his remaining years to the preparation of his "Memoirs of the Revolution" (2 vols. New York, 1802), a work particularly valuable to the student of American history.

MOUND, a term used technically in the United States as synonymous with barrow or tumulus, designating a large class of aboriginal antiquities or earth works, scattered throughout the valleys of the Mississippi river and its tributaries, but also found in New York, Pennsylvania, and other states to the E. of the Allegheny mountains. The term is also understood to include those vast lines of circumvallation or embankment, often regular in form in walls regarded as sacred or symbolical, and some-

times irregular, enclosing defensible positions, and obviously of military origin, found in the Mississippi valley. (See *AMERICAN ANTIQUITIES*.)

MOUNT, WILLIAM SIDNEY, an American artist, born in Setauket, Long island, Nov. 26, 1807. He was bred a farmer's boy, but at the age of 17 removed to New York and became an apprentice to his brother, Henry S. Mount, who was then by profession a sign painter. Showing a strong taste for art, he was in 1826 placed in the school of the national academy of design, and in 1828 produced his first picture, a portrait of himself. In 1829 he established himself in New York as a portrait painter, and at the same time attempted scriptural pieces, such as the "Raising of the Daughter of Jairus," and "Saul and the Witch of Endor." A "Rustic Dance," which appeared in the exhibition of 1830, attracted much attention. His pictures of humorous subjects have since been numerous. Negro physiognomy and scenes of negro life in particular have been treated by him with success. Among his best known works are: "Men husking Corn," "Walking the Crack," "The Sportsman's last Visit," "The Raffle," "The Courtship," "Nooning," "Bargaining for a Horse," "The Power of Music," "Music is Contagious," "Just in Time," "California News," "The Lucky Throw," "Banjo Player," "Bone Player," &c., several of which have been widely distributed through the medium of colored lithographs. He has also steadily practised portrait painting down to the present time. Since 1832 he has been a member of the national academy of design.

MOUNT AUBURN. See *CAMBRIDGE, MASS.*

MOUNT DESERT, an island of the state of Maine, at the southern extremity of Hancock co., situated in Frenchman's bay, about 40 m. S. E. from Bangor, lat 44° 20' N., long. 68° 30' W.; pop. in 1850, 3,509. The island is 15 m. long and 12 broad, and has an area of about 100 sq. m. It is divided into 3 towns or townships, Eden, Tremont, and Mount Desert, and contains 6 small villages, 9 post offices, 51 schools, and 8 churches. There are several good harbors. Ship building is carried on, and many vessels owned in the island are employed in the cod and mackerel fisheries. A narrow bay or sound runs from the ocean at the S. side of the island into the interior in a northerly direction to the distance of 6 or 8 m. The scenery of the island is very grand and beautiful. The greater part of its surface is covered by a group of granite mountains 13 in number, whose highest peak, Mt. Adam or Mt. Green, rises to an elevation above the sea variously computed at 1,500 and 2,300 feet. High up among the mountains are many beautiful lakes, the largest of which is several miles in length; these lakes and the streams that flow from them abound in trout. The S. E. coast of the island is lined with stupendous cliffs several hundred feet in height; the most remarkable of these are Great Head and Schooner Head. In Frenchman's bay, on the E. side of Mount Desert, are 5 high

rocky islands called the Porcupines, and about 20 m. to the southward in the open ocean is Mount Desert rock, the site of a noted lighthouse. Mount Desert is much resorted to in summer by artists and others for the beauty of its scenery, and is connected by steamer with Rockland, Bangor, Portland, and Boston. The island was discovered and named by the French about the beginning of the 17th century. M. De La Saussaye and Fathers Quentin, Lalemant, Biard, and Masse, with 25 colonists from France, landed here in May, 1613, built a small fort and a few cabins, and called the place St. Saviour. This settlement was forcibly broken up in a few weeks by Gov. Argall of Virginia. The first permanent settlement on Mount Desert was made by Abraham Somes, who in 1761 built a house at the head of the sound.

MOUNT EVEREST. See *HIMALAYA MOUNTAINS*, vol. ix. p. 176.

MOUNT MITCHELL. See *BLACK MOUNTAINS*.

MOUNT VERNON. I. The capital of Knox co., Ohio, on the Vernon river, and on the line of the Sandusky, Mansfield, and Newark, and the Springfield, Mount Vernon, and Pittsburg railroads (the latter completed only to Delaware, 22 m. from Mount Vernon), 45 m. N. E. from Columbus; pop. in 1859, about 7,000. It is well and compactly built on gently ascending ground, is lighted with gas, has many elegant mansions, and in 1859 contained 26 stores, a bank, 2 flour mills, 2 saw mills, 8 or 10 churches, and 3 newspaper offices. II. The capital of Posey co., Ind., situated on a bend of the Ohio river, about 160 m. S. W. from Indianapolis; pop. in 1859, about 2,500. It contains, beside the county buildings, 15 stores, a bank, 2 hotels, 2 steam flour mills, 2 saw mills, several manufactories, a foundery, planing mill, 7 churches, and a number of schools and benevolent and literary institutions, and has 2 weekly newspapers.

MOUNT VERNON, the home and burial place of George Washington, situated on the right bank of the Potomac, in Fairfax co., Va., 9 m. S. by W. from Alexandria and 15 m. from Washington city. At the time of Washington's decease the estate comprised several thousand acres, divided into farms devoted to different kinds of culture. The mansion is beautifully situated on a swelling height crowned with trees and commanding a fine view up and down the Potomac. The house is of wood, two stories in height and 96 feet in length, with a lofty portico extending along the whole front. On the ground floor are 6 rooms, none large except the dining room. The library and Washington's bedroom remain as they were at the time of his death, and contain many articles of great interest. In front of the house sloping to the river is a lawn of 5 or 6 acres. About 300 yards S. of the mansion, on a hillside in full view of the river, is the old family vault, where the body of Washington was first laid and remained till 1830, when it was removed to a new vault

at no great distance on the edge of a deep wooded dell. Mount Vernon mansion was built by George Washington's elder brother Lawrence, who settled there in 1743, and named the estate in honor of Admiral Vernon, under whom he had served in the West Indies. George Washington added wings to the mansion, and greatly enlarged and embellished the estate, which was his home from boyhood till his death, when by his will it was bequeathed to Bushrod Washington, from whom it passed into the possession of his nephew John A. Washington. By him it was sold in 1858 for \$200,000 to the "Ladies' Mount Vernon Association," who design to hold it in perpetuity as a place of public resort and pilgrimage. Means have been collected by private subscription and by the efforts of Mr. Edward Everett to pay the purchase money, of which at present (Nov. 1860) only \$2,000 remains unpaid, and to establish a fund for keeping the place in order. Their purchase comprises the mansion, the tomb, and 200 acres of the original estate. About \$20,000, beside what has been paid to Mr. Washington, has already been expended upon it.

MOUNTAIN, THE (Fr. *la montagne*), a name applied during the French revolution to a party in the convention which occupied the highest benches on the left. The deputies composing it were the most ultra of the revolutionists and the leaders of the Jacobins and Cordeliers. From the fall of the Girondists to that of Robespierre they were the ruling party. By degrees the name came to denote any association of persons of similar principles to the deputies of the extreme left, and nearly every commune in France had its *montagne*. In the constituent assembly of 1848 and the legislative assembly of 1849-'52 the appellation was revived.

MOUNTAINS, portions of the earth's surface which rise to a great height above the level of the sea, in the form of peaks and ridges, and groups of these called chains. The elevation which gives to them the name of mountains is considerable, not in relation to the great body of the globe itself, in comparison with which the irregularities of the surface are insignificant, but as it appears to the limited observation of man, and is accompanied by changes of climate and of vegetable productions, which in a level country would be effected only by differences of many degrees of latitude. Thus the high peaks of the Himalaya and of the Andes, mounting into regions inaccessible to man, and to his view presenting the sublimest objects in nature—their feet among the palms of the tropics, and their summits covered with the never wasting snows of polar climes—are really of so trifling height, that upon a map of the globe spread out even over 80 feet in length a bit of pasteboard placed upon the spots they occupy would fairly represent by its thickness their proportional elevation. The slight difference of 850 feet in height is equivalent in its effect upon the mean temperature to a difference of latitude of 60 miles, each being accompanied by a change of

about 1° F.—The mountains of the earth rarely occur isolated, but in groups and chains; and those of the eastern and western hemispheres present several marked distinctions. In each the principal chains range with the greatest longitudinal extent of the continent they traverse; but in the new world this is on the meridians, while in the old it is on the parallels of latitude. In North and South America the chains are comparatively narrow, and are composed of numbers of parallel ridges, which with great uniformity in their features continue near together sometimes for several hundred miles. In the old world much less regularity is perceived in the distribution of the mountains. The chains widen out over broad territories, and several chains in neighboring groups are connected together by high table-lands or plateaux, from which rise the loftiest mountains upon the globe. This is the case with the great mountainous district of central Asia, 1,500 miles in width, upon the range of the chains from northern Africa to the N. E. coast of Asia. Upon these belts the ridges are rarely found in parallel lines, as in the American continent, but more commonly diverging from each other, and in northern China spreading out like a fan. In the new world the line of the coast on the Pacific side lies along the range of the Andes, by which it seems to be determined; and that of the Atlantic shows a marked conformity to the general direction of the Alleghanies at the north and of the Brazilian mountains at the south; but in the old world this connection is less obvious. Still in both hemispheres it is observed that all the great chains present toward the Pacific and its extension, the Indian ocean, their steeper slope, the opposite slope subsiding over immense tracts of gradually diminishing elevation toward the opposite oceans. This consideration, in connection with the numerous volcanoes in action around the borders of the Pacific and upon its islands, has led to the belief that the vast basin of this ocean was occupied by a continent that has sunk and disappeared in one of the latest great revolutions of the surface.—The geological formations of which mountains are composed belong to different periods, as is evident from the fossil remains they contain; and thus it is that one group is referred for the time of its uplifting to an epoch as recent as the carboniferous, another to that of the jurassic, another to the tertiary, &c. By comparing together the various mountain chains, M. Élie de Beaumont detected a correspondence between their general directions and the period of their elevation, and was thus led to group them into systems, each system comprising all the chains, in whatever part of the world they might be found, which lay on parallel courses. The theory has lost much of the favor with which it was received, it being found that the number of systems would equal the number of points of the compass, and a single chain in some cases proving to be the result of successive elevations at different geological epochs. But, how-

ever this may prove, the same geological formations impress upon the mountains they compose a similarity of form and appearance. And thus it is that, whether in one hemisphere or the other, the bold and rugged slopes with projecting masses of rock are seen to be of granitic character; the rounded gentle slopes betray the calcareous strata within; the high needle-like peaks suggest the mode of weathering peculiar to the crystalline slates and gneiss; the precipitous walls marked in vertical lines tell of basaltic columns; and the conical isolated hills, with their truncated horizontal summits, are monuments of volcanic fires, that may have been extinguished long previous to any human records. So through many other varieties of outward form the accustomed eye recognizes the rock (hidden it may be beneath the soil and vegetation) to which these surface outlines are peculiar. The steepness of the slopes of mountains, as remarked by Mrs. Somerville in her work on "Physical Geography," is very generally and curiously exaggerated. Vertical precipices of great height are very rare; in the whole range of the Alps there is not one 1,600 feet high; and the surface of many in other regions as well as this, which seems to approach this degree of steepness, proves to be on the other side of 45° , or nearer the horizontal line. Thus on the steep sides of Mont Blanc, toward the Allée Blanche, the slopes are less than 45° ; and the mean inclination of the peak of Teneriffe is given by Humboldt at only $12^\circ 38'$. The Silla of Caracas, which rises precipitously from the Caribbean sea, at an angle of $53^\circ 28'$, to the height of between 6,000 and 7,000 feet, is a majestic instance of perhaps the nearest approach to perpendicularity of any great height yet known.—Though the height of mountains is insignificant in comparison with the dimensions of the globe, their influence upon climate, the precipitation of rain, and the circulation of the winds, is of immense importance to the human race. This is treated under various heads in this work, as ANDES, GHAUTS, HIMALAYA MOUNTAINS, METEOROLOGY, RAIN, WINDS, &c.—The highest summits upon the globe are among the Himalaya mountains, and of these the most elevated peak is Mt. Everest, the height of which above the level of the sea is 29,002 feet. Several other peaks rise from 25,000 to over 28,000 feet. Great numbers of mountains in Asia exceed 15,000 feet. In the Andes the Nevado de Sorato is 25,300 feet high, and the two summits of Nevado Illimani rise 24,200 and 24,450 feet above the sea. Chimborazo is 21,440 feet high, and Cotopaxi, the highest active volcano in the world, 18,858 feet. In Mexico the volcano of Popocatepetl is 17,720 feet high, and the plateau of Mexico 7,500 feet. That of California is 6,000 feet high. The highest peaks of the Sierra Nevada are from 15,000 to 17,000 feet high. The highest summits of the Rocky mountains are 13,500 feet. Of the Appalachian mountains there are 12 peaks in North Carolina from 6,300 to 6,700 feet in height. (See

BLACK MOUNTAINS.) Mt. Washington in New Hampshire is 6,285 feet high, Mt. Katahdin in Maine about 5,000, and Tahawus in New York 5,837. In Europe the highest mountains are Mont Blanc, 15,775 feet; Monte Rosa, 15,150; and Finster-Aarhorn, 14,106. Several peaks among the Pyrénées exceed 11,000 feet. Mt. Etna is 10,874 feet, and Vesuvius 8,978. The mountains of Abyssinia, in Africa, attain the height of 18,000 feet, and Kilimandjaro and other snow-covered mountains in the countries south of Abyssinia are supposed to be still higher. The peak of Teneriffe in the Canary islands is 12,180 feet high, and the Table mountain of the Cape of Good Hope 8,582 feet.

MOUNTAINS OF THE MOON, a mountain range said to exist in central Africa, in which Ptolemy and other ancient geographers placed the sources of the Nile. On modern maps, until recently, the name was given to a great range which was supposed to cross the continent from E. to W., from the Indian ocean to the Atlantic, at the general distance of 8° or 10° N. of the equator. It is now known, however, that no such range exists, and the name was recently applied by the African explorer Capt. Speke to a range N. of the newly discovered lake Tanganyika, though incorrectly, according to his fellow traveller, Capt. R. T. Burton.

MOURAVIEFF. See MURAVIEFF.

MOURNING, an outward manifestation of grief, particularly on occasions of death. Every nation has some conventional form of mourning. The ancient Hebrews tore their garments, dishevelled their hair, threw dust or ashes on the head, and abstained from washing. During the time of mourning they sat on the ground, and went bareheaded and barefooted. The usual period of mourning was 7 days, but for Moses and Aaron they mourned a month. On public occasions professional mourning women were employed. The modern Hebrews preserve to a great extent the customs of their forefathers, such as sitting on the ground, and making an incision in some part of their clothing to symbolize the old tearing of garments. This last practice was observed by the Egyptians, who also sprinkled their heads with dust and ashes, struck their breasts, allowed their hair to grow and their dress to hang neglected, went unwashed, and abstained from wine and other delicacies. The women ran crying through the streets with disordered hair and exposed bosoms. The Lycians, regarding grief as unmanly, had a law which compelled men when they went into mourning to put on female garments. The Syrians wept for their dead during a number of days in solitary places.—The Greeks withdrew into retirement, cut off their hair, put on black, or in some states, as Argos, white garments, rolled themselves in the dust or mire, threw ashes on their heads, tore their clothes, never appeared in public without a veil, lacerated their faces, and frequently uttered the exclamation \bar{e} , \bar{e} , \bar{e} , in a mournful tone. When a popular general died, the whole army cut off their hair and the manes

of their horses. In Athens the duration of mourning was about 30 days; in Sparta it was 11 days.—The Roman forms of mourning did not differ greatly from the Grecian. In the time of the republic the color of the mourning dress was black for both sexes, and it always continued so for men; but during the reign of Augustus a white veil was worn by women, and subsequently a complete costume of white became their conventional token of sorrow. Ornaments for the person were laid aside, and the men, instead of cropping their hair and beards, let them grow long. The extreme duration of mourning was 10 months, but this period was abridged by the occurrence of any auspicious event, such as the birth of a child, the happening of any piece of good fortune to the family, certain religious feasts, or the consecration of a temple. The period of public mourning for the death of a great person or for a public disaster was fixed by special decree. At such times the forum, baths, shops, temples, schools of exercise, and other places of concourse were closed, the senators put aside the laticlave, the consuls sat on a lower seat than usual, and the magistrates appeared without their badges of office. On private occasions the mourning was done almost wholly by the women; the men wore black only for a few days, and the domestic ceremonies in honor of the deceased terminated on the 9th day after the funeral with a sacrifice called *novendiale*. A widow who married again during her time of mourning for a husband (10 months or a year) was accounted infamous and debarred from inheriting of her late spouse. Persons in mourning kept within doors, and the custom of tearing the garments was sometimes practised. Hired mourning women were employed at funerals by both Romans and Greeks.—Among the modern Syrians mourning women play a very important part at funerals, and frequently perform their avocation in a really affecting manner. There is no fixed period of mourning, the ceremonies, which are repeated at certain intervals, being indefinitely prolonged according to the relationship of the deceased and the wealth of the survivors. It is not unusual for families in moderate circumstances to be ruined by the expensive feasts and other commemorations which are held for weeks after the funeral. In the old tombs which have been opened in Palestine, as well as in Greece and Rome, are found lachrymatories or tear bottles, in which, as we read in ancient authors, it was customary for mourners to preserve their tears.—In Arabia the men wear no mourning, the women stain their hands and feet with ink, which they suffer to remain for 8 days, during this time they abstain from milk on the ground that its white color ill accords with the gloom of their minds. The hired mourning women of Medina dance before the house of the deceased, tearing their arms, faces, and heads, and uttering the fiercest imprecations.—The Chinese mourn in white, and on the death of a near relative every article of clothing, from the cord which ties up their queue

down to the shoes, must be of that color. Less intense affliction is indicated simply by caps and girdles of white linen, and a very moderate degree of grief by shoes and queue cords of blue. Mourning on occasion of the death of a parent or husband is enforced by the penalties of 60 blows and a year's banishment. The duration of mourning is fixed by law. For a father or mother it is 3 years, but in the case of government officers it has been reduced to 27 months. During this period of mourning a Chinese cannot perform the duties of any public office. For 30 days after the demise the nearest kindred must not shave their heads nor change their dress, but rather exhibit a slovenly and slipshod appearance. When the emperor dies all his subjects let their hair grow for 100 days. At funerals the relatives of the deceased furnish all who take part in the procession with mourning dresses, just as gloves and scarfs are given at the present day in Europe and America. They employ mourning women, whose faculty of shedding tears was remarked by Father Huc as something extraordinary.—The Japanese mourning color also is white, but it is a remarkable fact that relatives in the ascending line and seniors neither mourn for their junior kindred nor go to their funerals. Persons in mourning stay at home for 50 days, abstain from animal food and from the intoxicating liquor *saki*, and neither shave their heads nor pare their nails. This period of 50 days, called the *imi*, is succeeded by the *buku*, or 13 months of a sort of "second mourning," during which it is not allowed to wear bright colors or enter a Shinto temple. These long periods are only observed on the death of parents; for other relatives the *imi* and *buku* vary from 30 days and 13 months for a husband to 3 days and 7 days for cousins and their children. The laboring classes are not required to go into mourning at all, but some of them do so for 2 or 3 days.—In the Feejee islands, after the death of a chief, a general fast until evening is observed for 10 or 20 days, the women burn their bodies, and 50 or 100 fingers are amputated to be hung above the dead man's tomb. The ceremonies of domestic mourning consist of abstinence from delicate dishes, and from the use of oil on the person; the mourners sleep on the bare ground, and use only leaves for dress. These customs are optional; among those exacted by fashion are the "jumping of maggots," or a meeting of friends on the 4th day after the funeral to picture to themselves the corruption of the corpse, and the "causing to laugh" on the next night, when comic games are held. The introduction of a comic element in mourning was not confined to the Feejee islands, for a troop of buffoons used to exhibit their antics in the funeral processions of the Romans. About the 10th day of Feejee mourning the women scourge all the men except the highest chiefs. Among the natives of New Caledonia there is a custom for women to burn parts of their bodies in time of mourning. The Sandwich islanders denote

grief by painting the lower part of their faces black and knocking out their fore teeth.—Among all civilized modern nations there is a great similarity in mourning customs, and black is universally considered the proper color to be worn, although in the fashions for ladies' dresses modern refinement has gone so far as to symbolize the gradual change from the depth of affliction to a normal state of cheerfulness by a gradual return from black to the gay colors through the intermediate hues of purple and violet, which are recognized as "second mourning." The material of a mourning dress is also prescribed by fashion, being for ladies generally crape. The time varies, according to the degree of relationship of the deceased, from a week to a year, the latter being the period fixed by custom for a widow. Hired mourners are retained by the English, as attendants at funerals, but their office with them is one of mere show, and they are commonly called *mutes*. In some parts of Ireland, however, the *keeners* or professional mourners, generally old women, are famous for their extravagant lamentations. It was anciently the custom in England to give mourning rings and suits at funerals. On occasion of the burial of Samuel Pepys, the famous diarist (1708), 128 rings and 40 suits of mourning were thus distributed. In France, of old, the color of grief was white. Certain forms of private as well as public mourning were prescribed by Napoleon I., but went out of use at the restoration. Court mourning in Europe for members of the reigning family, even in remote degrees, is prescribed by ceremonials which give the minutest directions as to dress. The sovereign wears violet, except in England, where the color is black; but violet was formerly used there also. The courtiers appear in black. Court mourning seldom lasts more than 6 months. Public mourning, though rarer than it was of old, is not yet banished from the civilized world. It was witnessed in the United States on the death of Franklin, Washington, and Lafayette. Members of legislative, civic, military, and other associations usually wear a piece of crape on the left arm on public occasions for 30 days after the death of any one of their comrades.

MOUSE, the common name of the smaller members of the rodent sub-family *murinæ*. This sub-family is characterized by incisors smooth in front and compressed laterally; molars $\frac{2}{3}$ – $\frac{3}{4}$ or $\frac{3}{4}$ – $\frac{2}{3}$, rooted, the anterior the largest; the ante-orbital foramen a deep narrow slit, widening above; palate mostly on one plane; the descending branch of the lower jaw has not the angles above the plane of the crowns of the molars; other characters in the palate and lower jaw sufficiently distinguish them from *arvicolinæ* or meadow mice; feet usually naked beneath; the hind legs the longest and 5-toed, the anterior with only 4 and a kind of wart for a thumb; clavicles complete; tail more or less scaly, with hairs passing out between the whorls of the scales. They hold their food

in the fore paws, and sit on their haunches to eat it; most of them burrow and swim well. Reserving the larger species for the article **RAT**, this sub-family may be subdivided into two principal groups: *mures*, confined in the wild state entirely to the old world; and *sigmodontes*, exclusively American. The former have very large and broad molars, with 8 tubercles in each transverse series of the upper jaw; the latter have narrower molars, with 2 tubercles in each similar series. There is in the old world a 8d group, *merionides*, intermediate to the above, with plane molars and transverse complete lamellæ, found in Africa and central Asia.—In the murine group of this sub-family, the genus *mus* (Linn.) has the molars of opposite sides parallel to each other, no cheek pouches, the upper lip divided, the whiskers in 5 series, the nose sharp and hairy to the cleft, and the large, prominent ears nearly naked; the nails are short, pointed, and curved; palms naked, with 5 small balls, those of the hind feet the largest; the hair is soft and fine; the mammae are 10, 8 pairs on the lower abdomen and 2 pairs on the chest. More than 50 species are described, including the house rats; the only one here called a mouse is the common little creature of our houses (*M. musculus*, Linn.). This well known animal varies much in color, from almost black to pure white; the albino or white mice are a mere variety of the common animals, but have the ability of propagating their race *inter se*, as most pet-fanciers know; there have been several specimens seen recently of what are called "singing mice," which do not differ in appearance from ordinary mice, but which make, especially at night, a pleasing whistling noise somewhat like the feeble chirp of a canary bird. The house mouse was originally a native of Europe and central Asia, but is now spread over most inhabited regions of the world; in some parts of the United States, and particularly in newly settled districts, it is replaced by the white-footed mouse (described below), which commits about as much mischief in houses and out-buildings as the common mouse. Of European field mice may be mentioned the *M. sylvaticus* (Linn.), or wood mouse, found in fields and gardens, where they make large deposits of provisions in subterranean burrows, laying up grain, nuts, acorns, &c., for winter use. It is a smaller species than the house mouse, reddish gray above, and white below; the hind legs are so long that it moves by jumps, making the transition to *meriones* (Ill.). The harvest mouse (*M. minutus*, Pall.; *M. messorius*, Shaw) is only 2½ inches from end of nose to root of tail, this being about 2 inches more. These tiny and pretty mice make nests of leaves and straws among standing corn and in thistles, and are often carried into barns with the harvest, where they live and multiply; in winter they retire to burrows and corn ricks; the color is ruddy above and white below. The lineated mouse (*M. pumilio*, Gmel.), from the Cape of Good Hope, weighs less than

4 scruples (80 grains). Some mice of the genus *dendromys* (Smith) live on trees; the upper incisors are grooved, the fore feet 3-toed with a thumb-like wart, and the long tail is thinly haired and ringed; here belongs the *M. mesomelas* (Licht.).—Among the American or sigmodont mice will be mentioned here only the genera *reithrodon* (Waterh.) and *hesperomys* (Waterh.), as *neotoma* and *sigmodon* belong properly among the rats on account of the large size of all their species. In *reithrodon* the ears and tail are short and hairy, and the upper incisors are grooved longitudinally in front; 8 species of rat-like size have been found in the extreme southern portion of South America, while the North American ones resemble slender house mice; the body is depressed, limbs short, head broad and short, tail about as long as the body, thumb rudimentary and with a short nail, and heel hairy; the North American species are found in the southern states on the Atlantic border, and from St. Louis westward to the Rocky mountains, and to the Pacific territories. The harvest mouse (*R. humilis*, Baird) is about 2½ inches long, with the tail a trifle less; in color and general appearance it so nearly resembles a small house mouse, that it can only be distinguished at the first glance by the grooved incisors; the eyes are small; it is rarely injurious to the farmer, preferring grass lands to grain fields for its habitation. In *hesperomys* or the vesper mice, the typical species have long tails scantily-haired, large ears, the quick motions of the common mouse, and generally white feet and a whitish tail. The old genus was of very great extent, embracing a large portion of the American *muridae*; the South American species, most of them too large to be considered mice, have been arranged by Burmeister under the genera *calomys*, *habrothrix*, and *oxymycterus*, established by Waterhouse, the first resembling the common mouse, the 2d the meadow mice (*arvicola*), and the 3d the lemmings. Baird divides even the North American species into 3 groups, as follows: *hesperomys* (Waterh.), containing 18 species; *onychomys* (Baird), and *oryzomys* (Baird), each with a single species. In *hesperomys* the form is mouse-like, tail not less or even longer than the body without the head, claws weak, hind legs and feet long, and soles naked or less than half hairy. The white-footed or deer mouse (*H. leucopus*, Le Conte) is between 3 and 4 inches long, with tail about the same; the color of the adult is yellowish brown above, darker on the back, the lower parts of the body and tail and the upper surface of the feet white; the young are dark slaty; the eyes and ears are large, and the fur long and soft. It is distributed from Nova Scotia to Virginia, and as far west as the Mississippi, and is a common inhabitant of houses and barns; it is nocturnal in its habits, as active as a squirrel, nesting in trees, in the fields, in barns and houses, and making a dwelling resembling a bird's nest; it feeds principally on grain, seeds, nuts, and

acorns, and is very fond of maize; it produces 2 or 3 broods in a season, according to latitude, 5 or 6 at a birth; it is not very injurious to the farmer, most of the mischief commonly attributed to it being due to the *arvicola* or meadow mice; great numbers are destroyed by the smaller carnivorous mammals and birds. Allied species are found in Texas, California, the southern states, and on the Pacific coast. The cotton mouse (*H. gossypinus*, Le Conte) makes its nest under logs and in trees, often robbing the Georgia planter of more than a pound of cotton for a single nest. The hamster mouse (*H. myoides*, Gapper) has been mentioned under HAMSTER. The prairie mouse (*H. Michiganeensis*, Wagner) is 3½ inches long, with a tail of 1½ inches, and the smallest of the genus; the color is grayish brown above, whitish beneath, with the cheeks yellow. The Missouri mouse (*H. leucogaster*, Pr. Max.), the type of the group *onychomys*, has the clumsy form of the *arvicola*, tail less than half the head and body, claws large and fossorial, the posterior ⅔ of the soles densely furred, and the skull without crest; the body is 4 inches long and the tail 3½ inches; grayish brown above, passing into yellowish red and fulvous on the sides; feet and under surface of body and tail white; the eyes are large, the ears rather short, and the whiskers long; it lives on the seeds and roots of wild plants, and sometimes on corn. The rice-field mouse (*H. palustris*, Wag.), the type of *oryzomys* of Baird, has a rat-like form, ears nearly buried in the fur, coarse hair, tail longer than head and body, hind feet long, soles naked, and upper margin of the orbit raised into a compressed crest; it is over 5 inches long, and the tail about the same; the color is rusty brown above, and whitish below. It is found in the rice fields of Carolina and Georgia, burrowing in the dams just above the water line; it scratches up the newly planted rice, eats it in the milky state, and gleans it from the fields in autumn; it is a good swimmer and diver; it eats also seeds of marsh grasses, and sometimes small mollusks and crustaceans.

MOUTON, GEORGE. See LOBAT.

MOVERS, FRANZ KARL, a German orientalist, born in Koesfeld, Westphalia, July 17, 1806, died in Breslau, Sept. 28, 1856. He was the son of a watchmaker, and a member of the Roman Catholic church. He studied at Munster, was ordained in 1829, and officiated in the pulpit from 1830 to 1839, when he was appointed professor of Old Testament theology at the Catholic faculty of Breslau, which office he held till his death. His principal work, *Die Phönizier*, presents a comprehensive view of Phœnician history. The 1st volume (Breslau, 1840) treats of the religion and the divinities of the Phœnicians; the 2d volume bears the title of *Das Phönizische Alterthum*, and is divided into two parts, embracing the political history (1849) and the colonial history (1851) of that nation; the 1st part of the 3d volume (1856) treats of navigation and commerce.

MOWATT (RITCHIE), ANNA CORA, an American actress and authoress, born about 1821 in Bordeaux, France, where her father, Samuel G. Ogden, a merchant of New York, was then established in business. She was the 10th of a family of 17 children, and her early childhood was passed in an elegant chateau in the neighborhood of Bordeaux, in the private theatre attached to which she frequently participated in the juvenile dramatic performances with which her brothers and sisters were accustomed to amuse themselves. When she was about 6 years of age the family returned to New York, and Miss Ogden in the intervals of her daily studies devoted much time to reading and private dramatic entertainments. At the age of 14, while yet at school, she attracted the attention of James Mowatt, a lawyer of New York, to whom, with the consent of her parents, she was soon after engaged, with the understanding that she was not to be married until she had reached the age of 17. Before the appointed time, however, she made a runaway match with him. During the first two years of her married life she continued her studies with great diligence, and published also two poems, "Pelayo, or the Cavern of Covadonga," an epic in 5 cantos, and the "Reviewers Reviewed," a satire directed against the critics of the former poem. At the end of this period her health began to fail, and she made a visit of a year and a half to Europe, during which she wrote for private performance a play entitled "Gulzora, or the Persian Slave," which was afterward published. Not long after her return financial difficulties overtook her husband, and as a means of providing for their support she gave a series of public dramatic readings in Boston, Providence, New York, and other cities. The exertions incident to this career, however, produced a serious illness, and for two years she was a confirmed invalid. She employed herself during this interval in contributing articles to the magazines under the pseudonyme of Helen Berkley, and also wrote a 5 act comedy entitled "Fashion," produced at the Park theatre, New York, in March, 1845, with considerable success. In June of the same year she made her public debut at this theatre as Pauline in the "Lady of Lyons," and thenceforth for many years was a popular actress on the American stage. In 1847 she made an extended professional visit to England, where in 1851 her husband died; and in the latter part of 1854 she played a series of farewell engagements in the United States and left the stage. She was soon after married to Mr. W. F. Ritchie of Richmond, Va., and has since lived in retirement. Her remaining works are: "Armand," a drama produced in 1847, and in which, as in "Fashion," she took a prominent part; the "Fortune Hunter, a Novel of New York Society" (last ed., 1854); "Autobiography of an Actress" (New York, 1855); and "Mimic Life, or Before and Behind the Curtain" (New York, 1856).

MOWING AND REAPING MACHINES, mechanical devices now in general use in the United States and parts of Europe for cutting grain or grass by animal power. Though this important invention was suggested by the ancient Romans, it is believed that the first experiments tending toward practical results were made in Europe in the early part of the present century; while for its general usefulness and present perfection the world has acknowledged its obligations to the genius and enterprise of American inventors. The names of Smith, Bell, Gladstones, and Scott are well known as connected with the experimental working of this machine in England; and those of Hussey, McCormick, Ketchum, and Manny are familiar to nearly every American farmer, as among the many inventors who have improved it and demonstrated its practical utility. The first machines were constructed with the idea of imitating the hand process as nearly as possible. Cutters similar to the ordinary scythe or sickle were employed, and a rotary motion communicated to them through suitable mechanism, from the wheels supporting the machine. This plan of communicating power to the cutting device is still used, but the form and movement of the cutters have been materially changed. A series of small shears were substituted for the scythe or sickle, and these were again superseded by a single series of two-edged pointed knives, standing at right angles with and attached to a horizontal rod or long plate of metal, the whole resembling a saw plate with very coarse teeth. These cutters work through mortised, stationary fingers or guards, a series of which are permanently fixed to the front of the machine, and, being longer than the cutting teeth, project a short distance forward, thus gathering small portions of the grass or straw between them where it is clipped off by the rapid reciprocating passage of the cutters. This device proved superior to either of the others, and with its various modifications has been universally adopted by manufacturers. The names of Adams of New York, Ten Eyk of New Jersey, and Lane of Maine are among the earliest that appear as connected with the invention of harvesters in the United States; but in 1838 Obed Hussey, then of Cincinnati, O., patented a machine to which he applied the saw-toothed cutters and guards. This machine was at once put into practical operation, and, after annual experiments and modifications, was in 1835-'6 favorably noticed by the press. On July 12, 1837, a public exhibition of its operation was made under the direction of the board of trustees of the Maryland agricultural society for the eastern shore of Maryland, and was witnessed by several hundred persons, principally farmers, who expressed great satisfaction with the result. The board also awarded a handsome pair of silver cups to the inventor. During the same season this machine cut in a satisfactory manner 180 acres of oats and barley on a farm in Maryland. Though this implement

would hardly compare with the reaper of the present day, it may be said to have proved its utility, and laid a firm foundation for the experiments which have led to more modern inventions.—Owing to the variety in form and the multiplicity of patented modifications of the several parts of the modern machines, we will give a general description only of their construction and operation. These machines consist of a strong framework, so constructed as to support a driver's seat, the cutting mechanism, and, when used for harvesting grain, a platform on which the grain falls when cut, and from which it is raked or otherwise removed as often as a sufficient quantity for a bundle has accumulated thereon. This framework is somewhat longer than the width of the swath to be cut, which is usually 5 feet, more or less, and of sufficient width for the platform, say 8 feet, except when used for cutting grass, when the platform is dispensed with, as the mown grass is allowed to fall over the cutters directly upon the ground. On the front edge of the frame is fixed the cutting apparatus, consisting of a series of iron guards or pointed fingers which are permanently fastened to the frame and extend 7 inches, more or less, beyond its edge, parallel to each other, horizontal and pointing forward. They are about $8\frac{1}{4}$ inches apart, of suitable size, say $1\frac{1}{4}$ inches, at the base, lessening toward the point. Each guard has a horizontal mortise through it, and being on a line with each other they all form a continuous horizontal mortise or slit through the whole line of guards. The cutters are formed of thin triangular plates of steel, fastened to a straight flat rod or plate of metal. These steel plates are arranged side by side, resembling a saw with teeth 8 inches wide at their base and 4 inches long, sharp on both sides, and terminating in a point. This saw or cutting plate is passed through the slits in the guards with the teeth pointing forward and their points coming even with the centres of the guards. One end of the saw is connected to a crank, which receives a rapid motion through intermediate cog wheels, from the tractive force and motion of the main or driving wheel. The framework with all its mechanism is supported by two or more wheels, the driving wheel being much larger than the other, and the axles so constructed as to admit of the platform, cutters, &c., being horizontal and suspended within a few inches of the ground. The pole is so attached to the framework as to allow the team to walk before the machine on the stubble of the last swath, while the platform with the cutters on its front edge extends on the right at right angles with the direction of the horses, so that the guards and cutters are presented to the standing grain or grass. A large reel, in front

of and parallel with the series of cutters, is sometimes attached to the framework, and, being connected by a band or otherwise to the driving wheel, is made to revolve with it in the right direction to bend back the top of the standing grain or grass, past the cutters and over the platform, which tends to assist the cutting and to insure the backward fall of the grass upon the platform, or the ground in the rear of the machine. A seat for the driver is usually attached directly behind the team, above and over the driving wheel. Some of the machines used for harvesting grain have two seats, one for the driver of the team, and the other so attached to the framework as to seat the raker in a convenient position to remove the grain from the platform.—The litigations among patentees and others interested in the many improvements in these machines, have been so numerous and complicated that we must refer the reader to the records of the courts for all the particulars in relation to the specific claims and awards of the several inventors. But in justice to the genius and enterprise of the modern American inventors whose names appear at the commencement of this article, we may say that since McCormick's award for the best harvester at the industrial exhibition in London in 1851, an active competition for excellence has been carried on at our annual agricultural fairs, which has resulted in a pretty general distribution of prizes. Some patents have been granted for machines for reaping and threshing grain at the same operation, and many for a binding apparatus as an attachment to the reaper; but if any of these have proved successful, they are yet to be brought into general notice. J

MOXA, any substance whose gradual combustion on or near the skin is used as a remedy in disease. The mode of treatment was brought into Europe from China and Japan by the Portuguese, but has now fallen into comparative disuse on account of its severity, although in neuralgic and certain other complaints it is still sometimes recommended as an effective counter-irritant. The Chinese use for moxas a cone formed from the down of the leaf of a plant of the mugwort kind (*artemisia moxa*, De Candolle); but the down or pith of many other plants may be used, and the pith of the common sunflower answers very well. In the United States and Europe the operation is usually performed with a roll of cotton wool, which is held upon the skin by an instrument, set fire to at the top, and suffered to burn down. The moxa has often been used in conjunction with acupuncture, the combustible substance being perforated by the needle which is pushed into the flesh to convey the heat directly to the seat of the disease.
